*Like its predecessor (Stress)
written 25 years ago
this book is dedicated to those
who suffer from stress.*

TO those who—in their efforts for good or evil, for peace or war—have sustained wounds, loss of blood or exposure to extremes of temperature, hunger, fatigue, want of air, infections, poisons or deadly rays.

To those who are under the exhausting nervous strain of pursuing their ideal—whatever it may be. To the martyrs who sacrifice themselves for others, as well as to those hounded by selfish ambition, fear, jealousy,—and worst of all by hate.

FOR my stress stems from the urge to help and not to judge.

But most personally, this book is dedicated to her who helped so much to write it, for she understood that I cannot, and should not, be cured of my stress but merely taught to enjoy it.

FOREWORD

PURPOSE AND SCOPE

In our time, characterized by a rapid increase in the rate of medical and social developments, research on stress and adaptation to change assumes particular importance in health and disease. We can no longer count on "having finished our training" for our work or on "having arrived at our goal" in society; nowadays, the skills and knowledge demanded by any job, as indeed the goals of society itself, are developing (or at least changing) at such an unprecedented rate that our first objective must be to learn how to cope with the stress of adaptation to change as such, both in our work and in our social goals. Only thus can we hope to succeed in overcoming the distressing loss of stability and perhaps even to enjoy the challenge of adjustment to ever-changing tasks, aspirations and possibilities.

Of course, the need to adjust to constant change arises from the fact that the more we know and the larger the number of people who acquire knowledge, the faster the pace of development, or at least of exploratory change, in all fields. This situation is primarily created by recent progress in mathematics, physics, chemistry and engineering with its resulting industrial implications: computers, automation and extraordinary acceleration in the rate at which people and information travel and alter the world.

All this is durable, and sometimes even enjoyable, but only within the limits of human adaptability. In the final analysis, the mastery we gain over our inanimate surroundings and the psychosocial consequences thereof are essentially physiologic and medical problems.

For the reasons just mentioned, interest in stress as it influences the lives of individuals, and even entire societies, has grown enormously during the past few decades. There has been a phenomenal increase in the number of laboratories, technical articles, books, journals and congresses dealing with the far-reaching implications of stress in virtually all fields of human endeavor, including medicine, physiology, psychology, psychiatry, sociology and philosophy. Nowadays, even the lay press, television and radio are constantly discussing stress, although frequently without real awareness of the objective scientific proofs upon which certain conclusions are based.

The magnitude and danger of the resulting confusion stem mainly from the fact that, unlike all other research subjects, stress (as defined in medicine) affects every aspect of life in health and disease; indeed, it exerts an ever-increasing influence upon even the most sophisticated activities of the mind. A real understanding of stress is therefore essentially dependent upon a holistic and integrative approach; no special

aspect of it can be analyzed in depth without a full realization of where and how it fits into the whole picture.

These are the considerations that encouraged us to attempt the somewhat Herculean task of providing a guide to the seemingly limitless number of publications concerned with stress in all its aspects. This effort has been inspired by the daring (and perhaps somewhat overoptimistic) hope that stress research, at the present critical period in its history, could best be promoted by providing an easily available source of at least key references to all of its implications. Only thus could we facilitate ready access to relevant data for highly specialized scientists lacking the bibliographic resources for an overview of the entire concept, which data would allow a proper evaluation of their own findings relative to the whole.

Since the publication in 1936 of a letter to the editor of *Nature* on "A syndrome produced by diverse noxious agents," about ninety-five thousand articles, reviews and books have dealt with what has become known as the *Stress Syndrome* or *General Adaptation Syndrome* (*G.A.S.*). The documentation service and library attached to our Institute have made every effort to collect and fully index all relevant published data.

I cannot claim to have studied thoroughly every one of these works, but I have at least glanced through all of them to maintain an overview of the subject, while scrutinizing more closely those that struck me as particularly important. I was best aided in this effort by my long-standing involvement in the field since its birth almost forty years ago, when biologic stress as we now understand it was first described. During this time I have studied and lectured throughout the world at most of the centers where important stress research was being done. It was of considerable help to me on these trips, as well as in the evaluation of the literature, that my own varied personal background had forced me to acquire at least a working knowledge of most languages in which pertinent data are described; hence, I could read and speak to foreign scientists in their own tongues without excessive linguistic handicaps.

These are the credentials that emboldened me to undertake the task of selecting and evaluating what I consider key references. The resulting work is meant to include most of the important publications on the mechanism of stress reactions without limiting itself to these. Many data are mentioned merely because of the difficulty in finding publications on highly specialized topics (for example: stress in plants and uncommon animals and the applicability of the stress concept to problems of forensic medicine, executive life, diabetes, emigration, concentration camps, captivity, air-traffic control, urbanism and noise). On some of these subjects reliable data are scarce, and here even relatively unimportant papers are mentioned to give at least one or two key references. On the other hand, subjects that occupy the attention of a great many contemporary scientists—such as the mechanism of the stress reaction, its biochemical and morphologic indices, and its applications to psychology, psychiatry and sociology—are generously documented, even if available space permits only the briefest summary of the contents or merely the listing of a descriptive original title.

It is hardly possible to draw a sharp line between stress research as such and work on organs involved in the mechanism of stress reactions. In this treatise I give considerable attention to the types of agents that can act as stressors or modifiers ("conditioners") of the stress response, the role of nervous and hormonal mediators, and the diseases primarily dependent upon inappropriate reactions to stress, called "de-

railments of the G.A.S." On the other hand, only cursory mention is made of the embryology, anatomy, histology and physiology of nerve centers and endocrine glands, the biosynthesis and degradation of hormones and metabolic changes, except insofar as they are directly related to the stress concept. Thus, I do not deal with the embryology of the hypothalamo-pituitary system, the enzymatic mechanisms leading to the synthesis or secretion of corticoids, or the electron microscopic (EM) structure of the median eminence (ME) unless such topics are of particular interest for the interpretation of stress reactions. Even the effects of catecholamines, ACTH or corticoids are considered only in this limited sense.

A glance at the table of contents and the subject index will suffice to show the wide variety of topics that are thus included. They will readily guide the reader to any particular field (as does an encyclopedia or dictionary), without the need to wade through the rest of the text.

PREFATORY REMARKS ON THE STYLE OF THIS BOOK

General Structure. In five previous monographs, *The Mast Cells* (Butterworths, Washington, D.C., 1965), *Thrombohemorrhagic Phenomena* (Thomas, Springfield, Ill., 1966), *Anaphylactoid Edema* (Green, St. Louis, Mo., 1968), *Experimental Cardiovascular Diseases* (Springer-Verlag, Berlin, Heidelberg and New York, 1970), and *Hormones and Resistance* (Springer-Verlag, Berlin, Heidelberg and New York, 1971), I have tested the practicality of what might be called the *analytico-synthetic style*. In essence, it attempts to facilitate fact-finding by strictly separating: (1) the *analysis* of previous publications in search of facts, which must be objective, and (2) the author's evaluation and *synthesis* which, being guided by his personal experience, are largely subjective.

The lessons learned in compiling these earlier monographs are incorporated in the present treatise, and since no major changes in method have been made, the rationale of the analytico-synthetic style may be described here in essentially the same terms.

Conventionally, the preparation of a monograph progresses through two stages:

- (1) The author surveys the literature and makes brief abstracts of each publication pertinent to his subject.
- (2) In writing the successive chapters of his book, he transforms these abstracts into a current narrative.

In theory, this seems to be a perfectly logical procedure, and it can be successfully applied in some cases. However, the second phase of the work usually meets with virtually insurmountable difficulties. Whenever numerous data are accumulated by many investigators who have used different techniques, the interpretations may be consonant, contradictory or unrelated, so that a unified, concise report of all relevant facts and views is hardly possible without confusing distortions or oversimplifications.

Take a sentence such as "Allegedly, it is possible to augment corticosterone secretion by a single intravenous injection of substance X in the rabbit (Smith and Johnson, 1943; Jones, 1944; Jackson, 1952) but not in the mouse (Simpson, 1961; Walker, 1964); however, the latter claim has been challenged by several investigators (McKay, 1963; Dow, 1963; Fisher, 1964), who have obtained positive results in both these species." Did all these investigators use exactly the same technique? Did all of them use the same criteria for a "positive result?" Were the animals used of the same age and weight? Were the animals invariably killed after the same length of time following the injection, so as to give them an equal chance to develop the response? Only in the rarest instances would the answers to all these questions be affirmative. In other words, the sentence designed to combine the three reports has made them quite meaningless.

But why yield to the customary practice of verbal acrobatics to give the un-unifiable the appearance of unity? To make sense, the incongruous monster sentences painfully synthesized by the author must be broken down mentally into their constituent parts by the reader. What the author has coded, the reader must decode. Statements must be very diplomatically worked to fit several papers because the different authors bracketed after one remark have rarely, if ever, said exactly the same thing. Hence, such texts are difficult to read, and in the final analysis, they do little more than act as indices to the literature, which still must be procured and read in the original before it can serve as a reliable guide to further work. The essential weakness of this conventional style is that the author must formulate his remarks very vaguely whenever he wants to cite several related, but of course never identical, papers in support of a statement. This procedure is necessary for unification, but the result is uninformative or misleading; usually both.

I learned these facts by bitter experience while writing sixteen earlier medical texts in the conventional style. Could the usual drawbacks of monographs be avoided by a totally different approach? In compiling a scientific treatise, it is undoubtedly necessary first to peruse all pertinent publications and to prepare concise abstracts of them. (Indeed, I never minded this part of the work, for it was instructive and pleasant and gave me a panoramic view of the observations and reflections of others, the very basis for any correlative scientific study.) Then, however, came the deadly and uninstructive task of modifying and paraphrasing portions of my summaries so that they could be squeezed into more or less cohesive, current prose. Why bother? All that was accomplished in this second stage was to conform with the style sanctified by common usage, but in the process the practical value of my abstract collection was largely lost. I must admit that even after the book appeared in print, I usually still preferred to look up my original résumés. After all, the volume contained only portions of these, and even they were not expressed as clearly as in the abstracts, mainly for three reasons:

- (1) Whenever several references were cited to document a statement, certain details had to be eliminated or diluted to make the text fit all the supporting publications.
- (2) Transitional sentences were needed to connect one idea with another, and these were only confusing ballast that served no real purpose.
- (3) Many circumlocutions were necessary to distinguish tactfully between data that were fully, partly, or not at all, acceptable.

In other words, the first part of the work, the reading and abstracting, was pleasant, instructive and comparatively easy, while the second part, the paraphrasing into current narrative, was tedious and largely spoiled the earlier accomplishments.

Of course, a collection of abstracts is not a monograph; it does not possess any overall structure or continuity, and even with the aid of an extensive index, it cannot act as a handy guide to a new field. Such a compendium is also necessarily uncritical and devoid of originality. It gives none of the interpretations or personal findings of the reviewer.

How could I devise a style that would combine concise, objective reporting with original interpretations without creating any confusion between the two? How could the writing of scientific monographs be simplified sufficiently so that even a large field might be covered by a single author who could give it unity? This is what I have tried to accomplish, and the technique has been described in detail in *Experimental Cardiovascular Diseases* and in *Hormones and Resistance*.

References. In this treatise there is only one major deviation from the style used in my earlier analytico-synthetic works. Previously, the full references (title, journal, volume, inclusive page numbers and year) were listed at the end of the book, in alphabetic order (according to the senior author's name), with the accession number assigned by our library, whereas in the text each abstract was preceded only by the name of the author(s), followed by the same accession number. Hence the reader had to consult the bibliography for the details necessary to locate the publication in a library other than our own. In this treatise, each abstract is preceded by the complete reference. Often, the title itself yields enough information on the material discussed or even on the principal observations, making it possible for me to shorten, and sometimes even eliminate, abstracts. Each abstract provides data on the journal, number of pages and the original language in which the publication appeared. To facilitate orientation, there are section titles indicating the topic under discussion; in addition, the key words in abstracts or even in titles (when no abstracts were necessary) are *italicized*, especially in sections where many subjects are summarized under such titles as "Varia," "Metabolites," or "Other Hormones." Having made this statement here, we shall not have to repeat "italics mine" in quoted abstract texts or in abstract titles. In addition, all authors are now listed with the abstract; this is very useful because the senior author may not be the one whose work is best known to the reader.

Finally, an alphabetic Author Index is added at the end of the book. This includes even coworkers not mentioned in the first position of the publication itself, and gives each page number in the text where their work is cited. Thus, the complete reference is cited with each abstract and all text references to the work of any author or coauthor can be located by the page numbers after his name in the alphabetic Author Index.

Critique and Personal Observations. This classified collection of concise abstracts served as a convenient guide to the literature on the physiology and pathology of stress. However, precisely because of its strict objectivity and the absence of any connecting sentences between the abstracts, this text lacked both originality and continuity. It was useful for the experienced specialist who wanted only to consult the literature on a particular point, but it gave no guidance to the beginner and contributed no new unpublished thoughts or observations.

My published data are handled in the usual manner, in objective abstracts prepared for the small-print sections. However, my own interpretation of the literature and hitherto unpublished observations are reported in an entirely different, current narrative form; this text is clearly separated from the rest by being printed in large type. Here there are no references, it being tacitly understood that the conclusions are my own, based on a critical interpretation of the literature and on my personal experience. Only when a remark is to be attributed to one of the abstracts in the immediately following small-print section do I refer to its author(s) and serial number.

For the sake of clarity, the titles of groups and subgroups are printed in fonts of decreasing prominence. Italics are used to indicate the lowest groups or subdivisions in the original texts, abstracts and even in titles (where no abstracts are required) or quotations. They should not be interpreted as words emphasized by the original authors by means of italics or boldface print. In this treatise, the origin of foreign words or their importance is rarely emphasized by special fonts, except in a few cases where this is done by the use of italics.

Thus, we end up having a book within a book: the *small-print* sections representing concise and impersonal abstracts of published and unpublished data, formulated in telegraphic style, to be looked up but not to be read through from cover to cover; the *large-print* text being both a critical summary of the most noteworthy highlights in the literature and a description of unpublished observations. The reader who wishes only to get an overall view of the present status of knowledge on stress can do so without becoming lost in details and confusing contradictory statements if he reads only the large-type sections. The investigator who wants to verify a special point quickly will find it merely by consulting the classified abstracts in the corresponding section.

This analytico-synthetic style would not lend itself to the writing of textbooks for students, nor would it be suitable for monographs on entirely new subjects on which there is little if any earlier literature. However, I think it can be (and sometimes already has been) profitably employed in the compilation of doctoral theses, reviews or monographs that are to combine an extensive literature survey with personal observations and critical interpretations.

In our era, when interest in research has reached unprecedented proportions, one of the greatest handicaps to the further development of science is the growing difficulty in keeping track of the ever-expanding mass of literature. Hence, a generally acceptable, simplified style of reporting could be of immeasurable value. Of course, many laboratory men will say that they lack the time, money, library facilities, or the knowledge of foreign languages necessary for a thorough personal search of the original literature in an extensive field. Yet any competent scientist must master his own subject. The breadth of his investigations may be limited by lack of documentation, but in his restricted field he will eventually gather valuable expertise that should be made available to others as well. It is hoped that the extreme simplicity of reporting in the style recommended here will encourage the writing of surveys by authors who would not have ventured to do so in the more time-consuming conventional form. Should this be the case, correlative investigations would certainly receive a welcome stimulus at a time when mass production threatens to discourage the integration of knowledge.

Reviews

OUR EARLIER STRESS MONOGRAPHS

Selye, H.: *Stress*, p. 822. Montreal: Acta Inc., 1950.
B40,000/50

Selye, H.: *First Annual Report on Stress*, p. 644. Montreal: Acta Inc., 1951.
B58,650/51

Selye, H., Horava, A.: *Second Annual Report on Stress*, p. 526. Montreal: Acta Inc., 1952.
B87,000/52

Selye, H., Horava, A.: *Third Annual Report on Stress*, p. 637. Montreal: Acta Inc., 1953.
B90,100/53

Selye, H., Heuser, G.: *Fourth Annual Report on Stress*, p. 749. Montreal: Acta Inc., 1954.
C1,001/54

Selye, H., Heuser, G.: *Fifth Annual Report on Stress 1955-56*, p. 815. Montreal: Acta Inc., 1956.
C9,000/56

Each of the above monographs discusses 5,000-6,000 references directly connected with our subject. They are cited separately here because, to save space, we shall often refer to them conjointly as our earlier stress monographs. The large collection of find-

ings to which they refer will not be repeated in the present work, except where it is indispensable for the evaluation of new data.

The following references are subdivided into three sections:

1. *General*, which lists technical, English language reviews and books concerned with the entire G.A.S. concept,

2. *Popular*, which enumerates reviews and books on stress irrespective of language,

3. *Foreign*, which discusses technical data in languages other than English.

GENERAL

(See also our earlier stress monographs, p. xiii)

Selye, H.: "The alarm reaction." In: Piersol, G. M. and Bortz, E. L., *The Cyclo-pedia of Medicine, Surgery and Specialities*, Vol. 15, pp. 15-38. Philadelphia: F A Davis, 1940 (341 refs.). A8,048/40

Selye, H.: "The general adaptation syndrome and the diseases of adaptation." *J. Clin. Endocrinol.* 6: 117-230 (1946).

B1,204/46

First detailed review on the G.A.S. and the diseases of adaptation, presented in a special number of the *Journal of Clinical Endocrinology* (over 700 refs.).

Pincus, G.: "Studies of the role of the adrenal cortex in the stress of human subjects." *Rec. Prog. Horm. Res.* 1: 123-145 (1947). 98,426/47

Excellent review on the biochemical changes characteristic of the G.A.S. in man, with special reference to 17-KS excretion and blood count under the influence of circadian variations, the stresses of daily life, operating a Hoagland-Werthessen pursuit meter, flying and exposure to heat. The response of schizophrenics is abnormal in many respects, and the question is raised whether adrenal malfunction may play a pathogenic role in mental disease (20 refs.).

Selye, H.: *Textbook of Endocrinology*, p. 914. Montreal: Acta Endocrinologica, 2nd ed., 1949. 94,572/49

Textbook of endocrinology with an extensive section on the concept of the G.A.S. as it appeared before the discovery of cortisone.

Yacorzyński, G. K.: "The alarm and the general homeostatic syndrome (the adaptation syndrome of Selye) in psychopathological and psychosomatic relationships" (abstracted). *Am. Psychol.* 7: 347 (1952).

J13,183/52

Jensen, J.: *Modern Concepts in Medicine*, p. 636. St. Louis, Mo.: C V Mosby, 1953. B84,030/53

Voluminous treatise which attempts to reinterpret virtually the whole of physiology, biochemistry and medicine using the G.A.S. as a unifying concept. Very painstaking compilation of data interpreted in a rather daringly speculative manner.

Symposium on Stress, p. 332. Washington, D.C.: Army Medical Service Graduate School, 1953.

B87,548/53

Conference on stress sponsored by the Division of Medical Sciences, National Research Council and the Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington, D.C. Numerous papers on the hormonal and nervous regulation of stress responses, with special reference to combat situations, interpersonal relationships, nutrition and adaptation to catastrophic events.

Thorn, G. W., Jenkins, D., Laidlaw, J. C., Goetz, F. C., Reddy, W.: "Response of the adrenal cortex to stress in man." *Trans. Assoc. Am. Physicians* 66: 48-64 (1953).

B91,232/53

Noble, R. L.: "Physiology of the adrenal cortex." In: Pincus, G. and Thimann, K. V., *The Hormones. Physiology, Chemistry and Applications*, Vol. 3, pp. 685-819. New York and London: Academic Press, 1955.

C22,214/55

An extensive chapter on the adrenal cortex in an encyclopedia on hormones, with numerous discussions on the relation of corticoids to stress reactions (1,263 refs.).

Liebman, S. (ed.): *Stress Situations*, p. 144. Philadelphia and Montreal: J B Lippincott, 1955.

C4,030/55

Anthology of publications on emotional reactions to the stress of frustration, illness, catastrophes, marriage, fertility and sterility, divorce, death and suicide, presented in highly simplified lay language.

Hinkle, L. E. Jr.: "Physiological aspects of life stress." *J. Dent. Med.* 11: 69-77 (1956).

J13,193/56

Brief review on the role of the G.A.S. in "life stress."

Fox, H. M., Gifford, S., Murawski, B. J., Rizzo, N. D., Kudarauskas, E. N.: "Some methods of observing humans under stress." *Psychiatr. Res. Rep. APA* 7: 14-26 (1957).
J11,149/57

Review on the G.A.S. with special reference to behavioral changes in man.

Applezweig, M. H. (ed.): *Psychological Stress and Related Concepts: A Bibliography*, p. 185. Technical Report No. 7. New London, Conn.: Dept. of Psychology, Connecticut College, 1957.
J13,040/57

An extensive bibliographic list on stress, with special reference to the psychologic and psychosomatic implications of the G.A.S., but without annotations or comments (2,611 refs.).

Hambling, J. (ed.): *The Nature of Stress Disorder*, p. 298. Springfield, Ill.: Charles C Thomas, 1959.
E4,674/59

Proceedings of the Conference of the Society for Psychosomatic Research (Royal College of Physicians, London). Several experts discuss the G.A.S. on the basis of animal experiments and observations in man. Special sections deal with stress in aviation, skin disorders, gastrointestinal disease, industry and the family setting, as well as genetic predisposition.

Engel, G. L.: "A unified concept of health and disease." *Perspect. Biol. Med.* 3: 459-485 (1960).
J12,716/60

Singer, H. A.: "The management of stress." *Advanc. Management* 25: 11-13 (1960).
J14,314/60

Popular review on stress, especially as it affects the manager, with recommendations concerning the avoidance of distress.

Ganong, W. F., Forsham, P. H.: "Adenohypophysis and adrenal cortex." *Ann. Rev. Physiol.* 22: 579-614 (1960) (317 refs.).
C83,368/60

Messner, J.: "Über die Einheitlichkeit der Krankheitsabwehr im lebenden Organismus" (The uniform nature of disease defense in the living organism). *Z. Gesamt. Inn. Med.* 16: 111-117 (1961).
D5,855/61

Highly theoretical but extensive review on the uniformity of defensive phenomena in various diseases which suggest a participation of the stress mechanism (70 refs.).

Hamburg, D. A.: "The relevance of recent

evolutionary changes to human stress biology." In: Washburn, S., *Social Life of Early Man*, pp. 278-288. Chicago: Aldine, 1961.

J16,062/61

Farber, S. M., Mustacchi, P., Wilson, R. H. L. (eds.): *Man Under Stress*, p. 173. Berkeley and Los Angeles: University of California Press, 1964.
E4,227/64

Proceedings of a symposium organized by the University of California. A group of physicians, surgeons and basic research men (among them Brock Chisholm, René Dubos, Seymour Farber, Stanley Sarnoff, Hans Selye, Paul Dudley White) discussed various aspects of stress in relation to the philosophy of life, the social environment, cardiovascular disease and space medicine. Most of the speakers refrained from highly technical discussions, but key references to scientific papers are given.

Dubos, R.: *Man Adapting*, p. 527. New Haven and London: Yale University Press, 1965.
E10,710/65

Scientifically well-founded monograph on adaptation, with many sections referring to Cannon's "emergency reaction" and the G.A.S. The volume formed the subject of the Silliman Lectures at Yale University.

Edholm, O. G., Bacharach, A. L. (eds.): *The Physiology of Human Survival*, p. 581. New York and London: Academic Press, 1965.
E6,283/65

Monograph on human reactions to various stressors such as heat, cold, anoxia, high altitudes, compression and decompression, nutritional damage, sleep deprivation, monotony, fatigue, emotional arousal and muscular exercise. Each chapter is written by a specialist in the corresponding field, and numerous references indicate the difference between specific defense mechanisms and the stressor effect of the agents used.

Howard, A., Scott, R. A.: "A proposed framework for the analysis of stress in the human organism." *Behav. Sci.* 10: 141-160 (1965).
G40,977/65

An encompassing theoretical scheme which "proposes to reduce the conceptual barriers between various biochemical, physical, psychological, and sociocultural models of stress." Numerous references to the technical literature.

Weitz, J.: *Stress*. Research paper IDA/HQ 66-4672, pp. 251-294. Washington, D.C.: Inst. Defense Analyses, Research and Engi-

neering Support Div., 1966. J13,888/66

Review on stress research, particularly in relation to military medicine, with a section criticizing various currently used definitions of the term "stress" (16 refs.).

Levi, L.: *Stress, Sources, Management, and Prevention* (Foreword by Hans Selye), p. 192. New York: Liveright, 1967. E250/67

Very readable volume on the sources, management and prevention of stress, emphasizing both the purely medical and the psychologic aspects of everyday experiences.

Bajusz, E. (ed.): *Physiology and Pathology of Adaptation Mechanisms*, p. 583. Oxford, London and Edinburgh: Pergamon Press, 1969. E8,161/69

Technical monograph with independent articles by numerous specialists in adaptation. One large section deals with "the pituitary adrenocortical system, its regulation and adaptive functions," and another with "regulation of 'adaptive hormones' other than ACTH." Additional presentations are concerned with neuroendocrine regulatory adaptation mechanisms and adaptation to changes in environmental temperature.

Smelik, P. G.: "Integrated hypothalamic responses to stress." In: Martini, L., Motta, M. et al., *The Hypothalamus*, pp. 491-497. New York and London: Academic Press, 1970. J12,268/70

Dodge, D. L., Martin, W. T.: *Social Stress and Chronic Illness: Mortality Patterns in Industrial Society*, p. 331. Notre Dame, Ind., and London: University of Notre Dame Press, 1970. E10,654/70

Monograph attempting to evaluate modern concepts of systemic stress within the body in relation to social stressors.

* Harris, R.: "Stress." *Aust. Dent. J.* **16**: 255-256 (1971). J19,854/71

Levi, L. (ed.): *Society, Stress and Disease*, p. 485. New York, Toronto and London: Oxford University Press, 1971. E9,300/71

International Interdisciplinary Symposium sponsored by the University of Uppsala and the WHO. The principal subjects for discussion were: definition of problems and objectives of stress research, relationships between the G.A.S. and social adjustment, neuroendocrine function, potentially pathogenic psychosocial stressors in today's society, epidemiologic evidence for diseases produced by stressors, and possible ways of modifying or

preventing psychosomatic diseases through social action. First formulation of the definition: "biologic stress is the nonspecific response of the body to any demand made upon it." An excellent overview of contemporary ideas on the different somatic and psychic manifestations of stress. A rich source of useful references.

Selye, H.: *Hormones and Resistance*, 2 vols., p. 1140. New York, Heidelberg and Berlin: Springer-Verlag, 1971. G79,100/71

Very extensive encyclopedic treatise on the role of various hormones in resistance to specific and stressor agents. First detailed description of the difference between syntoxic and catatoxic hormones and the results of extensive screenings of steroids for these actions. Among all compounds tested, pregnenolone-16 α -carbonitrile (PCN) proved to be the most active catatoxic substance.

Grant, J. K., Hall, P. E.: "Laboratory investigation of the human hypothalamic-pituitary-adrenocortical system." *Scott. Med. J.* **16**: 157-167 (1971). G83,953/71

Review on the results of laboratory investigations on human hypothalamic-pituitary-adrenocortical reactions, especially to stress (about 50 refs.).

Levi, L.: "Definition and evaluation of stress." *Rep. Lab. Clin. Stress Res.* (Stockholm) No. 25: 1-11 (1971). G87,068/71

Review on the hormonal, nervous and cardiovascular indices of stress defined as "the nonspecific response of the body to any demand made upon it."

Buckley, J. P.: "Physiological effects of environmental stimuli." *J. Pharm. Sci.* **61**: 1175-1188 (1972). H57,401/72

Highly constructive and critical evaluation of the present status of the stress concept, cocorticoid elimination following delivery, based on technical literature (158 refs.).

Smelik, P. G.: "Neuroendocrine adaptation." *Prog. Brain Res.* **38**: 245-253 (1972). J11,298/72

Brief but excellent review on the G.A.S. and the diseases of adaptation.

Dottke, R. B.: "Intrapartaler Blutverlust und Stress Syndrom" (Hemorrhage during delivery and the stress syndrome), p. 63. Thesis, University of Berlin, 1972. J16,430/72

A detailed description of the G.A.S. and personal observations on the increase in glu-

especially when associated with severe hemorrhage.

Németh, Š.: *Hormones, Metabolism and Stress. Recent Progress and Perspectives* (Proc. Int. Symp. Smolenice, 1972), p. 322. Bratislava: Slovak Academy of Sciences, 1973. E10,453/73

Proceedings of a symposium primarily devoted to the mechanism of neuroendocrine interrelations in the regulation of the G.A.S.

Problems in Occupational Safety and Health: A Critical Review of Select Physical and Psychological Factors. Arlington, Va.: Staff Century Res. Corp. Pamphlet No. 2, p. 90 and 1,317 abstracts, 1973. J13,172/73

Annotated bibliography of 1,317 articles on occupational safety and accident proneness.

Selye, H.: "Stress without distress." *World Health* December, 1974, pp. 3-11. J4,263/74

Page, I. H.: "What is the role of stress in disease? New books on stress: more theories but little evidence." *Mod. Med.* August 19, 1974, pp. 26-27. J14,893/74

Introduction to a symposium on stress and psychosomatic medicine.

Levi, L.: "Psychosocial stress and disease: a conceptual model." In: Gunderson, E. K. E. and Rahe, R. H., *Life Stress and Illness*, pp. 8-33. Springfield, Ill.: Charles C Thomas, 1974. E10,679/74

Singleton, W. T.: "Comment." In: Gunderson, E. K. E. and Rahe, R. H., *Life Stress and Illness*, pp. 34-40. Springfield, Ill.: Charles C Thomas, 1974. E10,680/74

Comments on a symposium on stress in everyday life as related to disease.

Selye, H.: "The implications of the stress concept." *Biochem. Exp. Biol.* 11: 191-199 (1975). J4,260/75

Review on the stress concept with special emphasis upon its psychosocial implications.

Mason, J. W.: "A historical view of the 'stress' field. Part I." *J. Hum. Stress* 1 No. 1: 6-12 (1975). H97,891/75

Mason, J. W. "A historical view of the 'stress' field. Part II." *J. Hum. Stress* 1 No. 2: 22-36 (1975). H97,892/75

Review of the evolution of the stress concept from Cannon's work on the emergency discharge of EP during fight-or-flight reactions up to present day views on the importance of the hypothalamus-pituitary-adrenocortical system, the triphasic nature of the G.A.S., and the nonspecific stereotyped response pattern of the body to any demand. Eustress is not discussed, but the author emphasizes that "of all the known responses of higher organisms, emotional arousal is certainly one of the most ubiquitous or relatively 'nonspecific' reactions common to a great diversity of situations." However, he clearly recognizes that "this is not to conclude that the pituitary-adrenal cortical system responds only to psychological stimuli." In accordance with earlier work on the effect of internal and external conditioning factors upon the resulting reaction form, it is agreed that the response could not be absolutely nonspecific, even if it occurred after any demand (48 refs.).

Selye, H.: "Confusion and controversy in the stress field." *J. Hum. Stress* 1 No. 2: 37-44 (1975). J4,295/75

Reply to the preceding articles. "The continued use of the word stress as a non-specific response to any demand is deemed most desirable. The once vague term can now be applied in a well-defined sense and is accepted in all foreign languages as well, including those in which no such word existed previously in any sense. Subdivision of the stress concept has become necessary as more recent work has led to such notions as 'eustress,' 'distress,' 'systemic stress' and 'local stress.' Confusion between stress as both an agent and a result can be avoided only by the distinction between 'stress' and 'stressor.' It is explained that the stress syndrome is—by definition—nonspecific in its causation. However, depending upon conditioning factors, which can selectively influence the reactivity of certain organs, the same stressor can elicit different manifestations in different individuals."

Brooks, Ch. McC.: "Homeostasis and adaptation." In: Brooks, Ch. McC., Koizumi, K. et al., *The Life and Contributions of Walter Bradford Cannon 1871-1945*, pp. 84-86. Brooklyn, N.Y.: State University of New York Downstate Medical Center, 1975. E10,900/75

Comparison of Cannon's and Selye's approaches to the problems of homeostasis and adaptation.

Conn, J., Dorfman, A., Selye, H.: "Stress and disease." *University of Chicago Round Table*, December 10, 1950, No. 663, pp. 1-10. B67,642/50

A nontechnical round table discussion on the roles of stress and stress hormones in the pathogenesis of arthritis.

Wolff, H. G.: *Stress and Disease*, p. 199. Springfield, Ill.: Charles C Thomas, 1953. B82,545/53

Brief résumé in semitechnical language on the relationship between stress and disease (210 refs.).

Kennedy, J. A.: *Relax and Live*, p. 205. Englewood Cliffs, N.J.: Prentice-Hall, 1953. B90,700/53

Advice in lay language on how to relax and avoid disease. One section is devoted to the relationship between aging and the G.A.S.

Selye, H.: *The General Adaptation Syndrome in Its Relationships to Mental Health*. Proc. Fifth Int. Congr. Mental Health. Toronto, 1954. B94,999/54

Brief, popularized summary on the G.A.S. and the diseases of adaptation with special reference to mental health.

Selye, H.: *The Stress of Life*, p. 324. New York, Toronto and London: McGraw-Hill, 1956; 2nd ed., 1975. C19,000/56

First popularized explanation of the stress concept as presently used in medicine.

Gross, N. E.: *Living with Stress* (Foreword by Hans Selye), p. 207. New York, Toronto and London: McGraw-Hill, 1958. C60,445/58

Summary, in lay language, of the stress concept and its application to daily life.

Schindler, J. A.: *How to Live 365 Days a Year*, p. 222. Englewood Cliffs, N.J.: Prentice-Hall, 1959. C69,069/59

Recommendations on how to avoid psychosomatic illness, based primarily on the stress concept. Written exclusively for the lay reader.

Kerner, F.: *Stress and Your Heart* (Introduction by Hans Selye), p. 237. New York: Hawthorn Books, 1961. D5,450/61

Practical advice on the avoidance of cardiovascular disease resulting from stress, based principally on the technical monographs of Hans Selye.

Friedrich, R. (ed.): *Frontiers of Medicine*, p. 320. New York: Liveright, 1961. D24,182/61

Popularization of various new concepts in medicine (antibiotics, artificial hibernation, sleep therapy, and so on) with one section entitled "A New System: Selye's Theories of Stress and Adaptation."

Selye, H.: "The individual reaction to stress." In: *Man Under Stress: Proc. Conference No. VII*, pp. 31-37. San Francisco: University of California Press, 1963.

E24,103/63

Popular review on man's reaction to various stressors.

Summary of the stress concept in popular language.

Fraser, T. M.: "Men under stress." *Sci. Technol.* No. 73: 38-44, 82 (1968). F98,050/68

Semipopular review on men under stress, with special reference to environmental factors.

Selye, H.: "The problem finders." *Abbottempo* 7 No. 4: 20-23 (1969). G46,773/69

Description of the G.A.S., and various observations explaining, in nontechnical language, the problems posed by the introduction of new concepts into medicine.

Selye, H.: "Clinical implications of the stress concept." *Osteopath. Physician* March, 1970, pp. 22-31. G70,414/70

Semipopular outline of the G.A.S., the diseases of adaptation, and pluricausal diseases.

The Concept of "Stress." Story of Psychosomatic Medicine Pamphlet No. 2. Montreal, 1970. G78,380/70

Popularized summary of the stress concept, based mainly on *The Stress of Life*.

Selye, H.: "General adaptation syndrome or stress syndrome." In: Sahakian, W. S., *Psychopathology Today: Experimentation, Theory and Research*, pp. 200-213. Itasca, Ill.: F E Peacock, 1970. J4,226/70

Popular review on the G.A.S., representing a chapter in a textbook on psychopathology.

Selye, H.: "How to cope with stress." In: Cranfield, H. V., *The Empire Club of Canada. Addresses 1970-1971*, pp. 83-94. Ottawa: The Empire Club Foundation, 1971. G70,487/71

Popular lecture on stress and the diseases of adaptation with special reference to coping behavior.

Graham-Bonnalie, F. E.: *The Doctor's Guide to Living with Stress*, p. 148. New York: Drake, 1972. E10,624/72

McQuade, W.: "What stress can do to you." *Fortune* January, 1972, pp. 102-141. J21,322/72

Excellent popular review of the stress concept. Both the physiologic mechanism of stress and its implications in daily life—particularly its relationship to diseases—are discussed on the basis of interviews with various North American specialists in this field.

Blythe, P.: *Stress Disease. The Growing Plague*, p. 175. New York: St. Martin's Press, 1973. E10,704/73

Felstein, I.: *Living to be a Hundred. A Study of Old Age*, p. 200. Newton Abbot, England: David and Charles (Holdings), 1973. E10,768/73

Discussion on aging with special reference to the role played by the G.A.S.

Hardy, J. P.: "Le stress de 9 à 5" ("Stress: is your job killing you?") *Orbite 2* No. 4: 7-10 (1973) (published in French and English). J18,285/73

Hardy, J. P.: "Vivre avec son stress" (How to live with stress). *Orbite 2* No. 5: 1-3 (1973). J19,813/73

Selye, H.: "Le stress et la santé de la nation" (Stress and the nation's health). *Méd. Qué.* 8: 26-33 (1973). G39,905/73

Popularized summary of the G.A.S. and its implications regarding human behavior.

Selye, H.: *Guidelines to Living with Stress*, pp. 335-342. Proc. 1973 Ann. Meeting Million Dollar Round Table. Seattle, 1973. G70,458/73

Brief, popular summary of a code of ethics based exclusively on biologic laws rather than tradition or the commands of any unquestionable authority. Essentially, a preview of Selye's *Stress Without Distress*.

Chin, A., Mandel, H.: "The two faces of stress: a new look at the enemy." *Impetus* November, 1973, pp. 16-19; 53-59. H62,174/73

Popular review on the stress concept with special reference to the problems of executives.

Vester, F.: "Hormone und die Umwelt des Menschen" (Hormones and the surrounding world of man). *Die Kapsel* 31: 1343-1399 (1973). J10,473/73

Semipopular, excellently illustrated review on stress with special reference to its neurohumoral regulatory influence on aging and possible prophylactic measures.

McQuade, W., Aikman, A.: *Stress. What it is, what it can do to your health, how to fight back*, p. 243. New York: E P Dutton, 1974. E10,491/74

Popular treatise with a brief chapter on the mechanisms underlying stress. Gives many examples of stress and the diseases of adaptation as they appear in everyday life.

Preddie, C. K.: "An engineering analysis of man's reaction to stress." *Ont. Digest and Engin. Digest* February, 1974, pp. 5-7. J10,476/74

Popular review on biologic stress in comparison with engineering stresses.

How to Use This Book

In surveying the literature, I was keenly aware that my lack of expertise in many fields prevented me from making useful critical comments concerning certain sections. Hence, I have restricted my personal evaluation to those fields with which I am particularly familiar. In other areas, relevant data have merely been listed, especially when I felt that even consultation with colleagues would not help much, because the volume of known facts greatly exceeds the possibility of coordinating them all in an instructive manner. This is true, for example, of most sections concerning the "Nervous Mechanisms" involved in stress reactions, the innumerable "Stress Tests," and some of the poorly-understood "Diseases of Adaptation" in which the role of stress is not yet clearly established. In such instances, this treatise can only serve as a collection of data carefully arranged according to subjects, objectively described, and in the case of foreign publications, translated into English. With these facts in mind, I hope that the text will be of considerable heuristic value for those who want to do further research in a particular field without having to waste too much time accumulating, translating and abstracting pertinent publications. Texts of special interest should be consulted in the original, since our abstracts are intended only as a guide to selection. Full coverage of a topic will require consultation of related entries. Only some related entries could be pointed out by cross-references, and each reader will have his own view as to which material may be worth scanning for additional information.

Certain observations are listed somewhat arbitrarily either under Functional or under Morphologic Manifestations of Stress, for the two areas are often interdependent, and to repeat the same references under both headings would have added uselessly to the length and expense of the text. For example, connective tissue changes (wound healing, inflammation and so on) are discussed only under Morphologic Changes, and alterations in muscle contractility only under Functional Changes.

In many fields, the literature is seemingly quite contradictory, such as that concerning typical stress-induced changes in the secretion of thyroid hormones, STH or insulin, the variations in blood cholesterol and many other areas. It is characteristic of the difficulty investigators experience in finding pertinent data that these evident contradictions are often left without comment, frequently because the authors reporting one type of change are quite unaware of the multitude of data indicating opposite results to be "typical of stress." From the published evidence, it is often impossible to arrive at a suitable explanation. It must be kept in mind, however, that some determinations are made with inadequate techniques whose flaws are not obvious from the printed texts. Sometimes diurnal variations have not been considered in describing

How to Use This Book

In surveying the literature, I was keenly aware that my lack of expertise in many fields prevented me from making useful critical comments concerning certain sections. Hence, I have restricted my personal evaluation to those fields with which I am particularly familiar. In other areas, relevant data have merely been listed, especially when I felt that even consultation with colleagues would not help much, because the volume of known facts greatly exceeds the possibility of coordinating them all in an instructive manner. This is true, for example, of most sections concerning the "Nervous Mechanisms" involved in stress reactions, the innumerable "Stress Tests," and some of the poorly-understood "Diseases of Adaptation" in which the role of stress is not yet clearly established. In such instances, this treatise can only serve as a collection of data carefully arranged according to subjects, objectively described, and in the case of foreign publications, translated into English. With these facts in mind, I hope that the text will be of considerable heuristic value for those who want to do further research in a particular field without having to waste too much time accumulating, translating and abstracting pertinent publications. Texts of special interest should be consulted in the original, since our abstracts are intended only as a guide to selection. Full coverage of a topic will require consultation of related entries. Only some related entries could be pointed out by cross-references, and each reader will have his own view as to which material may be worth scanning for additional information.

Certain observations are listed somewhat arbitrarily either under Functional or under Morphologic Manifestations of Stress, for the two areas are often interdependent, and to repeat the same references under both headings would have added uselessly to the length and expense of the text. For example, connective tissue changes (wound healing, inflammation and so on) are discussed only under Morphologic Changes, and alterations in muscle contractility only under Functional Changes.

In many fields, the literature is seemingly quite contradictory, such as that concerning typical stress-induced changes in the secretion of thyroid hormones, STH or insulin, the variations in blood cholesterol and many other areas. It is characteristic of the difficulty investigators experience in finding pertinent data that these evident contradictions are often left without comment, frequently because the authors reporting one type of change are quite unaware of the multitude of data indicating opposite results to be "typical of stress." From the published evidence, it is often impossible to arrive at a suitable explanation. It must be kept in mind, however, that some determinations are made with inadequate techniques whose flaws are not obvious from the printed texts. Sometimes diurnal variations have not been considered in describing

the findings, or even in planning the studies. Furthermore, we must remember that there exist mutual antagonisms between various stress-induced changes. The effect of a stressor upon one parameter may depend largely upon inherited, dietary and other conditioning factors that influence another—a fact which is not always taken into consideration. For example, STH, corticoids, insulin and glucagon may interact among themselves and with other parameters; hence the determination of one hormone at one particular time in individuals of a certain species and of a certain age can virtually never be indicative of stress as such, even if it occurs under the influence of several stressors. Finally, many determinations of stress-dependent metabolites fail to consider blood levels in relation to rates of secretion, resynthesis and distribution, which may be influenced by many factors.

Such interactions among the effects of various stressors and conditioning agents are especially likely to confuse interpretations if, as is often the case, the investigators are not sufficiently aware of one of the most fundamental concepts in stress research, namely, that no agent is only a stressor, without specific effects of its own, and that no specific agent is completely devoid of all nonspecific (that is, stressor) effects. The best way to avoid errors in this vein is to accept as true stress-manifestations only those changes associated with exposure to all kinds of demands as long as these do not specifically nullify the nonspecific change under study. Thus, the hyperglycemic response to stress could not be expected if insulin is used as a stressor, any more than an increase in blood corticoid levels could occur if hypophysectomy or adrenalectomy were employed to cause increased demands for adaptation. Furthermore, the EP secretion classically elicited by fighting causes a decrease in the size of the spleen that is undoubtedly typical of the alarm reaction, although after repeated fights among animals, the spleen is often enlarged because of the associated wound infections. The same is true if an alarm reaction is produced by overloading the circulation with particulate substances that are stored in the RES cells of the spleen.

Perhaps the most useful advice I can give, especially to those not particularly familiar with stress research, is to consult the carefully-prepared Subject Index. There, virtually every topic discussed in the text is identified as such along with cross-references under diverse synonymous designations.

Although this encyclopedia attempts to cover the subject of stress as completely as possible from every point of view, it should be kept in mind that it is no longer possible to quote in a single monograph all papers dealing with the G.A.S. Moreover, unlike our earlier stress monographs, this treatise could not elaborate on subjects only indirectly related to stress, such as the structure or function of stress hormones (for example, catecholamines, corticoids, ACTH, CRF) or specific (not stress-dependent) problems related to common stressors, such as anxiety, trauma, infection and so on.

Those who wish to have more complete literature surveys on any particular subject may obtain them at cost from our documentation service by writing to the Chief Documentalist, Institute of Experimental Medicine and Surgery, University of Montreal, C.P. 6128, Montreal 101, Quebec, Canada.

Glossary*

This glossary furnishes succinct descriptions of some of the technical terms and abbreviations most commonly used in this treatise. For additional definitions, see the section on terminology (p. 14), as well as the corresponding entries in the Subject Index.

- ACTH** Adrenocorticotrophic hormone of the pituitary.
- ADH** Antidiuretic hormone. See **Vasopressin**.
- ADP** Adenosine diphosphate.
- AMP** Adenosine monophosphate.
- androgen** See **Testoid**.
- ANS** Autonomic nervous system.
- ARH** Adrenal regeneration hypertension.
- ATCs** Air-traffic controllers.
- ATP** Adenosine triphosphate.
- ATPase** An enzyme metabolizing ATP.
- BMR** Basal metabolic rate.
- BTS** Blue-tetrazolium-reducing steroids.
- cAMP** Cyclic adenosine monophosphate.
- catatoxic actions** Increased metabolic degradation and/or excretion of potentially toxic substances.
- catecholamines** Any of a group of biologic amines containing a catechol moiety (e.g., epinephrine, norepinephrine, dopamine).
- cGMP** Cyclic guanosine monophosphate.
- CHD** Coronary heart disease.
- CNS** Central nervous system.
- compound 48/80** A histamine liberator.
- conditioning actions** Actions that prepare an organism for a special type of response. These may be positive, sensitizing through the induction of receptivity (also known as permissive actions), or inhibitory, desensitizing (blocking actions).
- corticoids** Hormones of the adrenal cortex. It is customary to subdivide them into the anti-inflammatory glucocor-
- ticoids and proinflammatory mineralocorticoids.
- CRF** Corticotropin-releasing factor.
- CSF** Cerebrospinal fluid.
- DA** Dopamine.
- DCA** Desoxycorticosterone acetate.
- DMSO** Dimethyl sulfoxide.
- DOC** Desoxycorticosterone. Also known as **DOCA**.
- DOPA** Dihydroxyphenylalanine, an epinephrine derivative.
- dopamine** Aminoethylpyrocatechol, an antihypotensive agent.
- E** See **EP**.
- ECG** Electrocardiogram.
- ECT** Electroconvulsive therapy.
- ectohormone**. See **pheromone**.
- EEG** Electroencephalogram.
- EM** Electron microscopy.
- EMG** Electromyogram.
- EOG** Electrooculogram.
- EP** Epinephrine.
- ESCN** Electrolyte steroid cardiopathy with necrosis.
- FFA** Free fatty acids.
- FLA-63** Bis(4-methyl-1-homopiperazinyl-thiocarbonyl) disulphide (an inhibitor of dopamine- β -hydroxylase).
- folliculoid** Follicle hormone-like, gynecogenic, estrogenic, or estromimetic (e.g., estradiol, estrone).
- FSH** Follicle-stimulating hormone. A gonadotropic hormone of the pituitary.
- GABA** γ -aminobutyric acid.
- galvanic skin resistance** See **CSR**.

* Although linguistically the suffix “-trophic” (nourishing, nurturing) is more correct, the ending “-tropic” is likewise employed in the literature, and hence, throughout the text, the two are used interchangeably in such expressions as “gonadotrophic” (gonadotropic), “thyrotrophic” (thyrotropic), and “somatotrophic” (somatotropic).

- galvanic skin response** See **GSR**.
- G.A.S.** General adaptation syndrome.
- GDP** Guanosine diphosphate.
- GH** Growth hormone. See **STH**.
- glucocorticoid** Possessing the effects of the carbohydrate-active hormones of the adrenal cortex (e.g., cortisol, corticosterone, dexamethasone).
- GMP** Guanosine monophosphate.
- GPT** Glutamic pyruvic transaminase.
- CSR** Galvanic skin response. A change in electric resistance of the skin which serves as a dependent variable in conditioning and is used in lie detection tests.
- CTP** Guanosine triphosphate.
- 5-HIAA** See **5-hydroxyindoleacetic acid**.
- 5-HT** 5-Hydroxytryptamine or serotonin.
- 5-HTP** 5-Hydroxytryptophan.
- 5-hydroxyindoleacetic acid** Principal metabolite of 5-HT.
- 4-hydroxy-3-methoxy-mandelic acid** See **Vanillylmandelic acid**.
- Ig** Immunoglobulin.
- 17-KGS** 17-Ketogenic steroids.
- 17-KS** 17-Ketosteroids. Principally, metabolites of corticoids and testoids (androgens).
- lactotropic hormone** See **LTH** or **prolactin**.
- L.A.S.** Local adaptation syndrome.
- LDH** Lactic dehydrogenase.
- L-dopa** Levadopa.
- LH** Luteinizing hormone. A gonadotropic hormone of the anterior pituitary.
- LH-RF** LH-releasing factor. See **LH**.
- LPL** Lipoprotein lipase.
- LRF** Luteinizing releasing factor.
- LTH** Luteotropic or lactotropic hormone, synonym of prolactin.
- luteoid** Corpus luteum hormone-like, progestational, gestagenic, progestagenic (e.g., progesterone).
- MAD** Methylandrostenediol. A testoid hormone capable of being transformed into a mineralocorticoid within the adrenal.
- MAO** Monoamine oxidase.
- MBH** Medial basal hypothalamus.
- ME** median eminence.
- ME-CRF** CRF produced by the median eminence.
- α -methyl-p-tyrosine** See **α -MT**.
- α -methyltyrosine** See **α -MT**.
- MHPG** 3-Methoxy-4-hydroxyphenylglycol.
- mineralocorticoid** Possessing the effects of the salt metabolism regulating hormones of the adrenal cortex (e.g., aldosterone, DOC).
- MSH** See **MTH**.
- α -MT** α -methyl-p-tyrosine, an inhibitor of tyrosine hydroxylase.
- MTH** Melanophorotropic hormone. Also known as MSH (Melanophore-stimulating hormone of the middle lobe of the pituitary, which increases deposition of melanin in the melanocytes).
- NAHD** The NAHD reaction of Camber (1949), a histochemical demonstration of ketosteroids in tissue.
- NADPH** Reduced nicotinamide-adenine dinucleotide phosphate.
- NDV** Newcastle disease virus.
- NE** See **NEP**.
- NEP** Norepinephrine.
- NPN** Nonprotein nitrogen.
- 11- or 17-OHCS** 11- or 17-Hydroxycorticosteroids. Commonly-used indicators of corticoids.
- 18-OH-DOC** 18-Hydroxy-desoxycortosterone.
- PAS** Periodic acid Schiff.
- PBI** Protein-bound iodine.
- PCN** pregnenolone- 16α -carbonitrile.
- PCPA** p-Chlorophenylalanine. An agent blocking 5-HT synthesis.
- PGR** Psychogalvanic reflex.
- pH** Hydrogen-ion concentration.
- pheromones** Substances secreted externally by one individual and received by a second individual of the same species whose behavior or develop-

- ment they modify. Also known as ectohormones.
- PK** Pyruvate kinase.
- PPLO** Pleuropneumonia-like organisms or "micoplasma."
- prolactin** See LTH.
- RER** Rough endoplasmic reticulum.
- RES** Reticuloendothelial system.
- RF** Reticular formation; term also used for releasing factors of pituitary hormones.
- SER** Smooth endoplasmic reticulum.
- SGOT** Serum glutamic oxalacetic transaminase.
- SH** Sulfhydryl groups.
- STH** Somatotropic or growth hormone.
- STH-RF** STH-releasing factor. See STH.
- syntoxic actions** Stimulation of biologic responses that permit coexistence with potential pathogens by increasing the resistance of the host's tissues, without attacking the pathogens.
- T3** Triiodothyronine, or thyroid hormone.
- T4** Tetraiodothyronine, thyroxine.
- testoid** Male hormone-like, androgenic, andromimetic (e.g., androsterone, testosterone).
- THC** Tetrahydrocannabinol.
- TM** Transcendental Meditation.
- TPNH** Reduced triphosphopyridine nucleotide, the former name for the reduced form of nicotinamide-adenine dinucleotide phosphate.
- TSH** See TTH.
- TRH** Thyrotropin-releasing hormone.
- TTH** Thyrotropic hormone of the anterior pituitary.
- TTH-RF** TTH-releasing factor. See TTH.
- UMP** Uridine monophosphate.
- vanillinemandelic acid** See vanillylmandelic acid.
- vanillylmandelic acid** A major metabolite of catecholamines excreted in the urine. (Also designated vanillinemandelic acid or VMA.)
- vasopressin** A pressor and antidiuretic hormone of the posterior pituitary. (Also designated ADH.)
- VDM** Vasodepressor material.
- VEM** Vasooexcitatory material.
- VMA** See vanillylmandelic acid.
- Indicates action on (e.g., A→B means: effect of A on B).
- + Refers to two agents given simultaneously (e.g., A+B means: A given conjointly with B).

Stress Tests

The most commonly used stress tests are listed here with their abbreviations.

- AAR** Adjusted Averaged Evoked Response Questionnaire.
- APQ** Autonomic Perception Questionnaire.
- BPI** Berkeley Psychological Inventory.
- BUPI** Boston University Personality Inventory.
- CFF** Critical Flicker Fusion.
- CMACL** Composite Mood Adjective Check List.
- CMI** Cornell Medical Index.
- CST** Controlled Stress Test.
- EPI** Eysenck Personality Inventory.
- FPJP** Frequency of Perceived Job Pressure.
- GSR** Galvanic skin resistance (or response, or reflex).
- HOS** Health Opinion Survey.
- HSTT** Harrower Stress Tolerance Test.
- IES** Impulse Expression Scale.
- IPAT Anxiety Scale** Institute for Personality and Ability Testing Anxiety Scale.
- JAS** Jenkins Activity Survey.
- LCI** Life Change Inventory.
- LCU** Life Change Unit.

- LEI** Life Events Inventory.
- MARS** Manifest Affect Rating Scale.
- MAS** See **TMAS**.

ACKNOWLEDGMENTS

I would like to take this opportunity to express my heartfelt gratitude to my associates, graduate students, technicians, secretaries, photographers and others who, through forty years, have helped me in many of the experiments that form the subject matter of this treatise as well as in the compilation of our unique documentation service on stress. Unfortunately, all of them cannot be mentioned here individually. Those whose names do appear here have done far more than the work that could be expected of them because of the positions they held. Many of them—especially the editors—have given generously of their free time, working at night and often on weekends to meet deadlines, in order to bring out this book before its author succumbs to his own “stress in health and disease.”

Mr. Kai Nielsen, my chief technician for thirty-five years (now retired), and Mrs. Irene Mécs, my chief scientific assistant in charge of laboratory matters for the last seventeen years, have been principally responsible for the organization of all laboratory and administrative activities. Mrs. Mécs was assisted in these matters especially by Giselle Maheu, Ginette Samuel and Lucette Kubat.

In connection with the writing of the present treatise, my gratitude is due first of all to Mr. Ovid Da Silva, Chief of our Editorial Department, and to his colleagues Geoffrey Languedoc, Cynthia Alperowicz, Gertrude Dore and Dan Saykaly. They worked as a perfect team, not only in editing the text but also in collaborating with the Documentation and Library Departments of our Institute, the typists and proof-readers. They piloted the work through the innumerable difficulties of synchronizing all activities necessary for the publication of a treatise such as this.

A great deal of credit must also be given to Mr. Antonio Rodriguez, Chief Documentalist, and his staff (Marianne Timm, Vesna Blazina, and Tora Hylten-Cavallius), who have gone through more than 100,000 publications on stress, indexing them and underlining key passages to facilitate my task of selection and critical evaluation.

Mrs. Rolande Rioux (assisted by Ginette Larue, Marguerite Samson, Marie-Suzanne Samson, Manon Bergeron, Guy Belanger, Marie Foucreault, Marguerite Desfosses, Anita Gagne, Roland Hamel and Olinda Rebouco) ingeniously collected even the least accessible literature, a crucial task in the preparation of a book of this kind, which depends so largely upon the completeness of its bibliography.

Except for about fifty quite inaccessible but important publications, no work was discussed on the basis of second-hand information obtained from references made by others. All works unavailable to us in the original form were obtained from other libraries for photoreproduction.

Finally, I would like to express my thanks to Mrs. Annette Amar, Chief of our Secretariat who, with her associate Arlette Guirguis, looked after the correspondence

and the coordination of typographic work, as well as to Maret Rutishauser and Franca Intrevado, who did much of the typing and proofreading.

It is only fair to add that I must take responsibility for any errors that may have occurred in the selection, abstraction or interpretation of the papers quoted.

This treatise and the original experimental work done at our Institute were subsidized in part by: the Medical Research Council of Canada; the Conseil de la recherche médicale du Québec; the Ministère des affaires sociales du Québec; the Fondation Canadienne des maladies du coeur; the Fondation du Québec des maladies du coeur; Fondation J. A. DeSève; the U.S. Army Medical Research and Development Command; the U.S. Department of Health, Education and Welfare; the National Library of Medicine; the U.S. National Institute of Child Health and Human Development; Wyeth Laboratories; Biermans Foundation; the Pfizer Foundation; Smith, Kline and French Laboratories; Hoffman-La Roche Inc.; the Population Council, New York, U.S.A.; the Cancer Research Society Inc.; the Canadian Tobacco Industry; the Council for Tobacco Research, U.S.A.; the Colonial Research Institute, Freeport, Bahamas; Banner Gelatin Products Corp.; the John A. Hartford Foundation; Reader's Digest; the World Health Organization; the Emko Company; UHU Werk Fisher, West Germany; the Geridex Foundation; the Killam Award of the National Research Council; Fondation Aldina, Fontaine, Hamel; Dr. Madaus & Company; the Upjohn Company; G.D. Searle & Company; and Schering AG.

I. HISTORY AND GENERAL OUTLINE OF THE STRESS CONCEPT

HISTORY

(See also under headings of various agents, changes, and mechanisms known to be characteristic of stress.)

Prescientific Intuitive Feelings Foreshadowing the Existence of Stress

The concept of stress is very old. It must have occurred even to prehistoric man that there was something common in the loss of vigor and the feeling of exhaustion that overcame him after hard labor, prolonged exposure to cold or heat, loss of blood, agonizing fear or any kind of disease. He may not have been conscious of the uniformity of his response to anything that was just too much for him, but when the feeling came he must have realized that he had exceeded the limits of what he could reasonably handle; in other words, that "he had had it."

Man soon must have discovered also that whenever faced with a prolonged and unaccustomed strenuous task—be it swimming in cold water, lifting rocks or going without food—he passes through three stages: at first the experience is a hardship; then he gets used to it; but finally he cannot stand it any longer. He did not think of this three-phase response as a general law regulating the behavior of living beings faced with an exacting task. The immediate necessities of finding food and shelter kept him too busy to meditate about such concepts as homeostasis, the maintenance of the *milieu intérieur*, or biologic stress. Yet the vague outlines of all this were there, ready to be analyzed and translated from intuitive feelings into the precise terms of science, a language that can be appraised by intellect and tested by the critique of reason.

How could different agents produce the same result? Is there a nonspecific adaptive reaction to change as such? In 1926, as a second-year medical student, I first came across this problem of a stereotyped response to any exacting task. The story of its elucidation has been told many times, although it is still unfinished, but here are the salient points:

I began to wonder why patients suffering from the most diverse diseases have so many signs and symptoms in common. Whether a man suffers from a severe loss of blood, an infectious disease or advanced cancer, he loses his appetite, his muscular strength and his ambition to accomplish anything; usually the patient also loses

weight, and even his facial expression betrays that he is ill. What is the scientific basis of what I thought of at the time as the "syndrome of just being sick"? Could the mechanism of this syndrome be analyzed by modern scientific techniques? Could it be reduced to its elements and expressed in the precise terms of biochemistry, biophysics and morphology?

The concept that every specific disease must have its own particular cause gained acceptance mainly during the nineteenth century. Following the emergence of modern bacteriology, it became evident that the characteristic syndrome of any one infectious malady, such as tuberculosis or diphtheria, could be elicited only by its own specific germ. Research in the field of nutrition and endocrinology similarly showed that one kind of derangement can always be traced to the lack or the excess of a particular vitamin or hormone.

Very few diseases are moncausal in the sense that their development is the inevitable consequence of one particular cause (as is, for example, a skin burn, paralysis after spinal cord transection or sterility following ovariectomy). Many maladies are predominantly pluricausal in that the "soil factor" (individual variations of disease proneness) plays an important role: influenza does not befall all persons exposed to an influenza virus, but only the susceptible ones. The typical pluricausal diseases are not caused by any particular pathogen but are the consequence of "pathogenic constellations." To this group belong peptic ulcers, accidental thymus involution, many forms of collagen disease, nephrosclerosis, thrombohemorrhagic lesions, atopic dermatitis, various neuroses and many other diseases. In fact, the possibility of a pluricausal pathogenesis must be considered in the case of all "idiopathic" maladies.

The history of this field suggests that the key to real progress in stress research was the discovery of three objective indices of stress: adrenal enlargement, thymicolumphatic atrophy and acute gastrointestinal ulcers. Yet even these signs were known to some physicians long before we began to realize that there is such a thing as a nonspecific stress syndrome. In England, as early as 1823 Swan, and in 1842, Curling, described acute gastrointestinal ulcers in patients who suffered extensive skin burns. In 1867, the German surgeon Billroth reported similar findings after major surgical interventions complicated by infections. But there was no reason to connect these lesions with other changes that today would be regarded as part of the stress syndrome—for example, with those described at the Pasteur Institute in Paris by Roux and Yersin, who noted that the adrenals of guinea pigs infected with diphtheria are often enlarged, bloodshot and hemorrhagic. In fact, these people did not even know about each other's work.

The so-called accidental thymus atrophy and the loss of body weight of individuals affected by disease have been described so often that it would be difficult to trace their history; but who would have thought of them in relation to Cannon's "emergency adrenalin secretion" in response to fear or rage? One important link was missing—that connecting all these phenomena as merely individual manifestations of a single coordinated syndrome.

Beginnings of a Scientific Analysis

It was not until 1936 that the problem presented itself again, now under conditions more suited to scientific analysis. At that time I was working in the Biochemistry Department of McGill University, trying to find a new hormone in extracts of cattle

ovaries. I injected the preparations into rats to see if their organs would show unpredictable changes that could not be attributed to any known hormone. Much to my satisfaction, even the first and most impure extracts caused a characteristic triad: (1) The adrenal cortex became enlarged and discharged its lipid secretory granules. (2) The thymus, spleen, lymph nodes and all other lymphatic structures showed severe involution.

(3) Deep, bleeding ulcers appeared in the stomach and duodenum.

The close interdependence of the three types of change implied a definite syndrome. The alterations varied from slight to pronounced, depending only upon the amount of extract injected.

At first I ascribed all these changes to a new sex hormone in the extracts. But soon I found that all toxic substances—extracts of kidney, spleen, or even a toxicant not derived from living tissue—produced the same syndrome. Gradually, my classroom concept of the “syndrome of just being sick” came back to me. I realized that the reaction I had produced with my impure extracts and toxic drugs was an experimental replica of this syndrome. Adrenal enlargement, thymicolymphatic involution, and gastrointestinal ulcers were the omnipresent signs of damage to the body when under attack. The three changes thus became the objective indices of stress and the basis for the development of the entire stress concept.

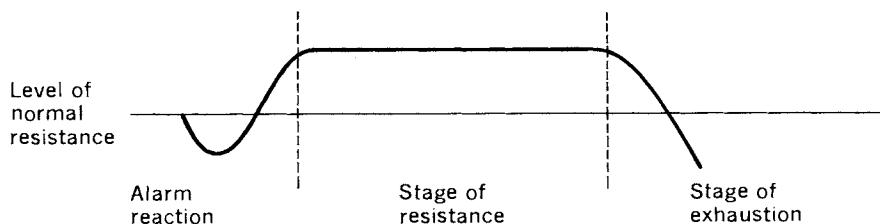

The reaction was first described in *Nature* (July 4, 1936) as “A syndrome produced by diverse noxious agents”; it subsequently became known as the *General Adaptation Syndrome* (*G.A.S.*) or biologic stress syndrome. In the same paper I suggested the name *alarm reaction* for the initial response, arguing that it probably represents the somatic expression of a generalized “call to arms” of the body’s defensive forces.

The General Adaptation Syndrome (G.A.S.)

The *alarm reaction*, however, was evidently not the entire response. Upon continued exposure of an organism to any noxious agent capable of eliciting this reaction, a stage of adaptation or resistance ensues. In other words, no organism can be maintained continuously in a state of alarm. If the agent is so damaging that continued exposure becomes incompatible with life, the animal dies during the alarm reaction within the first hours or days. If it can survive, this initial reaction is necessarily followed by the *stage of resistance*. The manifestations of this second phase are quite different from—indeed, often the exact opposite of—those characterizing the alarm reaction. For example, during the alarm reaction, the cells of the adrenal cortex discharge their secretory granules into the bloodstream and thus become depleted of corticoid-containing lipid storage material; but in the stage of resistance the cortex becomes particularly rich in secretory granules. Whereas in the alarm reaction there is hemoconcentration, hypochloremia and general tissue catabolism, during the stage of resistance there is hemodilution, hyperchloremia and anabolism, with a return towards normal body weight (Figure 1).

Curiously, after still more exposure to the noxious agent, the acquired adaptation is lost again. The animal enters a third phase, the *stage of exhaustion*, which follows inexorably if the stressor is severe enough and is applied for a sufficient length of time.

Because of its great practical importance, it should be pointed out that the triphasic

The body shows the changes characteristic of the first exposure to a stressor. At the same time, its resistance is diminished and, if the stressor is sufficiently strong (severe burns, extremes of temperature), death may result.

It ensues if continued exposure to the stressor is compatible with adaptation. The bodily signs characteristic of the alarm reaction have virtually disappeared and resistance rises above normal. Following long continued ex-

posure to the same stressor, to which the body has become adjusted, eventually adaptation energy is exhausted. The signs of the alarm reaction reappear, but now they are irreversible, and the individual dies.

Figure 1. The three stages of the G.A.S. (Reproduced from *Stress Without Distress*, Fig. 3, p. 39, 1974, by permission of the J B Lippincott Company).

nature of the G.A.S. gave us the first indication that the body's adaptability, or *adaptation energy*, is finite, since under constant stress, exhaustion eventually ensues. We still do not know precisely what is lost, except that it is not merely caloric energy, since food intake is normal during the stage of resistance. One would think that once adaptation has occurred and ample caloric energy is available, resistance should go on indefinitely. Not so. Just as any inanimate machine gradually wears out, so does the human machine sooner or later become the victim of constant wear and tear. These three stages are suggestive of childhood (with its characteristic low resistance and excessive responses to any kind of stimulus), adulthood (during which the body has adapted to most commonly encountered agents and resistance is increased), and senility (characterized by loss of adaptability and eventual exhaustion). Hence we suspected some relationship between stress and *aging*.

As is shown by the literature cited in this book, since 1936 numerous biochemical and structural changes of previously unknown origin have been traced to nonspecific stress. Among these, clinicians have given special attention to changes in the chemical constituents of the body and to nervous reactions. Much progress has also been made in the analysis of the hormonal mediation of stress reactions. It is now generally recognized that the emergency discharge of epinephrine (EP) during the "fight or flight" response of Cannon represents only one aspect of the acute phase of the alarm reaction to stressors. The hypothalamus-pituitary-adrenocortical axis is at least equally important for homeostasis, and it probably participates in the regulation of many disease phenomena as well.

History

(See also our earlier stress monographs, p. xiii)

Corvisart, J. N.: *An Essay on the Organic Diseases and Lesions of the Heart and Great*

Vessels. Boston: Bradford and Read, 1812.
E3,955/1812

All heart diseases stem "from the action of the organ and from the passions of man." The heart can be injured by crying in in-

fancy, wrestling, fencing, playing wind instruments, laughing, weeping, reading, declamation, anger, madness, fear, jealousy, terror, love, despair, joy, avarice, cupidity, ambition, revenge and "every kind of effort." However, "to conceive man without passions, is to conceive a being without his attributes."

Swan, J.: "Burns." *Mth. Gaz. Health* 8: 612-613 (1823). 6,901/1823

Swan, J.: "Practical observations." *Edinb. Med. J.* 19: 344-347 (1823). 11,389/1823

Probably the first descriptions of what is now known as a "stress ulcer," in a five-year-old child who died from severe burns. "At different times he vomited a blackish matter, and the day before he died, appeared so weak and cold, that a little wine and sago were given him. On opening the abdomen, every part appeared sound, except the stomach, in the villous coat of which were several black spots and stripes like sloughs, extending deep, and quite black... There can be no doubt that the diseased appearances of the head of the stomach were produced by the irritation of the skin."

Cooper, S.: "Pathology of burns and scalds." *Lond. Med. Gaz.* 23: 837-838 (1839). 72,145/1839

In an eight-year-old girl who died about five weeks after severe scalds of the chest, an ulcer "about the size of a shilling" was noted in the duodenum just beyond the pylorus. Duodenal ulcers were also found in other children after scalds and burns.

Long, J.: "On the post-mortem appearances found after burns." *Lond. Med. Gaz.* 25: 743-750 (1840). B4,643/1840

One of the first descriptions of perforating duodenal ulcers in eleven patients who died from extensive burns. "I have been induced to give the two cases of perforation of the duodenum in detail, as I believe they are unique; indeed I am not aware of any case being recorded, of perforation of the gastrointestinal tube occurring after a burn, except the one I have quoted from Liston, which approximates to my two cases by the perforation being near the pylorus, and by the change which had taken place in the duodenum."

Curling, T. B.: "On acute ulceration of the duodenum in cases of burns." *Tr. Med.-Chir. Soc. London* 25: 260 (1842).

B37,649/1842

One of the first descriptions of duodenal

ulcers in burned patients. Although the phenomenon had been discussed by several earlier investigators, these lesions are usually referred to as "Curling's ulcers."

Bernard, C.: *Introduction à l'étude de la médecine expérimentale* (Introduction to the study of experimental medicine), p. 302. Paris: Flammarion, 1945 (Original edition, 1865). B18,006/45

Recent annotated edition of Bernard's classic book combining the observations and interpretations published in various articles and books during the second half of the nineteenth century and culminating in the concept of the indispensability of the fixity of the *milieu intérieur*.

Billroth, T.: "Aus klinischen Vorträgen. I. Ueber Duodenalgeschwüre bei Septicämie" (From clinical lectures. I About duodenal ulcers in septicemia). *Wien. med. Wochenschr.* 17: 705-709 (1867). 23,917/1867

Description of patients with duodenal ulcers following septicemia as a consequence of operations on the thyroid and other causes. The so-called Curling's ulcer after extensive skin burns is also ascribed to the associated blood poisoning, that is, to sepsis.

Roux, E., Versin, A.: "Contribution à l'étude de la diphtérie" (Contribution to the study of diphtheria). *Ann. Inst. Pasteur* 3: 273-288 (1889). 7,004/1889

In guinea pigs treated with sublethal or lethal doses of diphtheria toxin, there are multiple hemorrhages in various organs, but the particularly constant feature is hyperemia of the adrenals.

Oppenheim, R.: "La fonction antitoxique des capsules surrénales. Etude expérimentale, anatomique et clinique de la glande surrénale dans les infections et les intoxications aiguës" (The antitoxic function of the adrenal glands. Experimental, anatomic and clinical study of the adrenal gland in acute infections and intoxications). Thesis, University of Paris, 1902. 6,966/02

Crude adrenal extracts, given intravenously, were found to be extremely toxic and imitated the actions of sympathetic stimulation. When such extracts were mixed with microbial poisons they tended to diminish the toxicity of the latter and to increase resistance. In severe intoxications, adrenal necroses and hemorrhages were virtually constant and could cause almost complete destruction of the glandular parenchyma. Such damage

could also be produced by intoxication with arsenic, phosphorus and mercury.

Cannon, W. B., Paz, D. de la: "Emotional stimulation of adrenal secretion." *Am. J. Physiol.* **28**: 64-70 (1911). 34,664/11

In cats frightened by the proximity of a barking dog, there was indirect physiologic evidence of EP secretion.

Cannon, W. B., Hoskins, R. G.: "The effects of asphyxia, hyperpnoea, and sensory stimulation on adrenal secretion." *Am. J. Physiol.* **29**: 274-279 (1911). 57,883/11

In cats, asphyxia or electric stimulation of the sciatic nerve, even when they were under anesthesia, caused increased EP secretion.

Cannon, W. B.: "The stimulation of adrenal secretion by emotional excitement." *Proc. Am. Phil. Soc.* **1**: 226-227 (1911).

35,529/11

Cannon, W. B.: "The emergency function of the adrenal medulla in pain and the major emotions." *Am. J. Physiol.* **33**: 356-372 (1914). 57,873/14

Reviews on the earliest animal experiments showing that fear, rage, asphyxia and pain cause a discharge of EP from the adrenal medulla and that this response is mediated through the splanchnic nerves. Direct stimulation of the latter exerts the same effect. The resulting glycogenolysis and increase in blood sugar furnish energy. At the same time blood circulation is improved. Stimulation of the splanchnics also hastens blood coagulation and thereby protects against bleeding in the event of injury. All these changes are "directly serviceable in making the organism more efficient in the struggle which fear or rage or pain may involve."

Cannon, W. B., Shohl, A. T., Wright, W. S.: "Emotional glycosuria." *Am. J. Physiol.* **29**: 280-287 (1912). B26,719/12

Personal observations on emotional glycosuria in cats separately caged next to a barking dog, and review of earlier literature on "Fesselungsdiabetes" elicited by restraint in cats, and on the appearance of diabetes in patients following severe emotional upset. The emotional glycosuria in cats following restraint is abolished by adrenalectomy, presumably as a consequence of EP-induced hyperglycemia. "A mobilization of sugar in the blood under these circumstances might be of signal service to the laboring muscles."

Kolosko: "Ueber Befunde an den Nebennieren bei Verbrennungstod" (Adrenal changes after death in burned patients). *Viertel Jschr. Gerichtl. Med.* **47** Supp.: 217 (1914). 3,525/14

Folin, O., Denis, W., Smillie, W. G.: "Some observations on 'emotional glycosuria' in man." *J. Biol. Chem.* **17**: 519-520 (1914).

58,703/14

Among students undergoing academic examinations, 18 percent exhibited at least traces of sugar in the urine. Hence, "mental and emotional strain may produce temporary glycosuria in man."

Crile, G. W.: *The Origin and Nature of the Emotions. Miscellaneous Papers*, p. 240. Philadelphia and London: W B Saunders, 1915. A32,669/15

First systematic monograph attempting to demonstrate the biochemical and morphologic basis of emotions in man and other animal species. Histologic examination of virtually all tissues of the body showed characteristic changes in three organs only: the brain, the adrenal medulla and the liver. These were essentially similar after emotional arousal and surgical shock. "The excessive use of alcohol, anesthetics, excessive work, intense emotion, all produce lesions of the kidney and of the liver. The explanation is found in the fact that all these stimuli increase the acidity of the blood, and that, if long continued, the neutralizing mechanism must be broken down and so the end-products of metabolism are insufficiently prepared for elimination. In view of these considerations we may well conclude that the maintenance of the normal potential alkalinity of the blood is to be estimated as the keystone of the foundation of life itself." Sleep rapidly restores these functions to normal. [The importance of this monograph is not so much due to new factual data reported, but to the great influence it exerted upon medical thinking in its time. It was very often quoted and greatly helped to call attention to essentially nonspecific reactions, although many of the allegedly nonspecific histologic and biochemical changes reported would no longer be acceptable today (H.S.).]

Weiskotten, H. G.: "Fatal superficial burns and the suprarenals. Note on the occurrence of suprarenal lesions in uncomplicated fatal cases of extensive superficial burns." *J.A.M.A.* **69**: 776 (1917). 92,580/17

In patients with widespread fatal superficial burns, the adrenals are usually swollen and deep red, exhibiting hemorrhages, necroses and polymorphonuclear cell infiltrations. Similar changes had been described by Kolosko in several cases of extensive superficial burns and were interpreted by him as hemorrhagic infarction.

Hammar, J. A.: "Beiträge zur Konstitutions-anatomie, VI" (Studies of the constitutional anatomy, VI). *Z. Angew. Anat. Konstat. Lehre* 4: 1-107 (1918). 50,856/18

Meticulous histologic studies on the human thymus with special sections on the so-called accidental involution elicited by various dietary deficiencies, bacterial infections, snake venoms and other damaging agents. This is probably the first systematic monograph on the subject.

Hollingshead, L., Barton, J. W.: "The adrenal cortex and emotion." *Psychol. Rev.* 38: 538-541 (1931). 91,447/31

After analyzing seven earlier publications concerning metabolic changes in cases of adrenal insufficiency, the authors formulate "the hypothesis that the adrenal cortical hormone is responsible for the variations in the non-protein nitrogen of the blood, and that the cortical hormone acts as an excitatory agent in emotional states." [This is probably the first publication on the relationship between the adrenal cortex and emotion, although it is based on data and arguments incompatible with contemporary knowledge (H.S.).]

Cannon, W. B.: *The Wisdom of the Body*, p. 332. New York: W W Norton, 1932. B14,905/32

Monograph in semipopularized style, but with many detailed descriptions of experiments which led to the concept of homeostasis.

Selye, H.: "A syndrome produced by diverse noxious agents." *Nature* 138: 32 (1936). 36,031/36

Brief Letter to the Editor describing the most characteristic signs of what is now known as the stress syndrome, particularly the thymicolymphatic involution, gastroduodenal ulcers, lipid discharge from the adrenal cortex and loss of chromaffinity in the medulla. Delimitation of the three stages. "We consider the first stage to be the expression of a general alarm of the organism when suddenly confronted with a critical situation,

and therefore term it the 'general alarm reaction.' Since the syndrome as a whole seems to represent a generalized effort of the organism to adapt itself to new conditions, it might be termed the 'general adaptation syndrome.'" The reaction is regarded as a non-specific adaptive response to various kinds of agents, and in view of its stereotypical appearance is ascribed to the liberation of some common initiating substance, possibly histamine.

Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* 17: 234-248 (1936). 36,032/36

First detailed description of the "alarm reaction" characterized by adrenocortical enlargement with acute loss of lipids, thymicolymphatic atrophy and decrease in body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for 48 hours or more, large doses of atropine, morphine, formaldehyde or EP). Adrenalectomy and to a lesser extent hypophysectomy prevent the thymus involution. "The changes caused by a drug when it is given for the first time will subside later in spite of the continued administration of this drug" but will greatly shorten survival. Perhaps the adrenal enlargement as well as the loss of body weight and the other manifestations of the alarm reaction enable the organism "to meet critical situations more efficiently."

Selye, H., Collip, J. B.: "Fundamental factors in the interpretation of stimuli influencing endocrine glands." *Endocrinology* 20: 667-672 (1936). 66,617/36

Stressors such as formaldehyde, which caused marked adrenal hypertrophy in normal but not in hypophysectomized rats, remained without effect even if the adrenal cortex was prevented from undergoing atrophy by the administration of a pituitary extract. "The effect of such a drug on the adrenal appears to be an indirect one, due to pituitary stimulation."

Selye, H.: "Studies on adaptation." *Endocrinology* 21: 169-188 (1937).

38,798/37

First detailed description of the three stages of the G.A.S. and the concept of "adaptation energy" with an extensive and illustrative characterization of the morphologic lesions produced by stress, especially in the

hypophysis, adrenals, thymicolumphatic apparatus, pancreas, gastrointestinal tract, and by inflammation (anaphylactoid edema).

Rogoff, J. M.: "A critique on the theory of emergency function of the adrenal glands: implications for psychology." *J. Gen. Psychol.* **32**: 249-268 (1945). B28,082/45

Summary of the literature, particularly the observations of the author and his coworker G. N. Stewart, in which Cannon's emergency theory is vehemently rejected. "The emergency theory concept of a direct relation of adrenal gland secretion to emotional excitation, or to painful stimulation, is untenable since it is based upon inadequate experimental investigations.... Endocrine implications for psychology that are based upon the premise of a direct and immediate endosecretory role in various bodily reactions are lacking in substantial experimental support."

Selye, H.: "The general adaptation syndrome and the diseases of adaptation." *J. Clin. Endocrinol.* **6**: 117-230 (1946).

B1,204/46

First detailed review on the G.A.S. and the diseases of adaptation, presented as a special number of the *Journal of Clinical Endocrinology* (over 700 refs.).

Green, J. D., Harris, G. W.: "The neurovascular link between the neurohypophysis and adenohypophysis." *J. Endocrinol.* **5**: 136-146 (1947). B1,426/47

In rabbits, monkeys and man, nervous connections between the neuro- and adenohypophysis are scanty. Vascular connections are prominent in rats, guinea pigs, rabbits, dogs and man, particularly between the capillary loops of the ME, infundibular stem and the hypophyseal portal vessels. These vessels are well supplied with nerve fibers. "It is suggested that the central nervous system regulates the activity of the adenohypophysis by means of a humoral relay through the hypophysial portal vessels."

Weiss, E., English, O. S.: *Psychosomatic Medicine*, p. 803. Philadelphia and London: W B Saunders, 1949. B48,177/49

Extensive although now somewhat outdated textbook of psychosomatic medicine with a rich collection of historically interesting references.

Selye, H.: *Stress*, p. 822. Montreal: Acta Inc., 1950. B40,000/50

First extensive monograph devoted exclusively to stress, discussing virtually the

entire relevant literature (including precursors of the stress concept).

Groot, J. de, Harris, G. W.: "Hypothalamic control of the anterior pituitary gland and blood lymphocytes." *J. Physiol. (Lond.)* **111**: 335-346 (1950). B54,598/50

"Electrical stimulation of the posterior region of the tuber cinereum or of the mammillary body, of unanaesthetized, unrestrained rabbits resulted in a lymphopenia, which was similar in time relations and magnitude to that following an emotional stress stimulus." This response was not abolished by cervical sympathectomy and could not be duplicated by stimulation of other hypothalamic areas. A similar psychogenic stress lymphopenia was abolished by lesions in the zona tuberalis, and by transverse lesions in the posterior tuber cinereum or mammillary body, but not by lesions in the pars distalis, pars intermedia, or by interruption of the infundibular stem. It is concluded that stress-induced ACTH secretion "is under neural control via the hypothalamus and the hypophysial portal vessels of the pituitary stalk." [This is the first clear-cut demonstration of the hypothalamic regulation of stress-induced ACTH secretion (H. S.).]

Selye, H.: *The Story of the Adaptation Syndrome*, p. 225. Montreal: Acta Inc., 1952. B71,000/52

Monograph outlining the historical development of the stress concept and the G.A.S.

Cannon, W. B.: *Bodily Changes in Pain, Hunger, Fear and Rage*, p. 404. Boston: Charles T Branford, 1953. A19,828/53

Excellent summary of the author's classic observations on the somatic manifestations of acute emotions, particularly with regard to the effect of fear, rage, hunger and thirst upon the sympathetic nervous system and EP secretion.

D16,010/61

Essentially a philosophic analysis of the history of medicine, primarily based on excerpts or direct quotations from the most important contributions of a variety of philosophers and physicians including Hippocrates, Aristophanes, Aristotle, Maimonides, Paracelsus, Sir Francis Bacon, R. T. H. Laennec, E. Darwin, O. W. Holmes, Sir William Osler, H. Cushing, Sir C. Sherrington, O. Loewi, Hans Zinsser, Albert Schweitzer, W. B. Cannon, Hans Selye, H. Sigerist and several others. The book makes interesting and instructive reading, and offers a judicious selection of aphorisms and pithy sentences about medicine in general. Four pages are devoted to an analysis of Selye's *The Stress of Life*.

Anthology of classic papers on the historical development of the homeostasis concept.

Mason, J. W.: "A historical view of the 'stress' field. Part I." *J. Hum. Stress* **1** No. 1: 6-12 (1975). H97,891/75

Mason, J. W.: "A historical view of the 'stress' field. Part II." *J. Hum. Stress* **1** No. 2: 22-36 (1975). H97,892/75

Review of the evolution of the stress concept from Cannon's work on the emergency discharge of EP during fight-or-flight reactions up to present day views on the importance of the hypothalamus-pituitary-adrenocortical system, the triphasic nature of the G.A.S., and the nonspecific stereotyped response pattern of the body to any demand. Eustress is not discussed, but the author emphasizes that "of all the known responses of higher organisms, emotional arousal is certainly one of the most ubiquitous or relatively 'nonspecific' reactions common to a

great diversity of situations." On the other hand, he clearly recognizes that "this is not to conclude that the pituitary-adrenal cortical system responds only to psychological stimuli." In accordance with earlier work on the effect of internal and external conditioning factors upon the resulting reaction form, it is agreed that the response could not be absolutely nonspecific, even if it occurred after any demand (48 refs.).

Selye, H.: "Confusion and controversy in the stress field." *J. Hum. Stress* **1** No. 2:37-44 (1975). J4,295/75

Answer to the preceding articles. "The continued use of the word stress as a nonspecific response to any demand is deemed most desirable. The once vague term can now be applied in a well-defined sense and is accepted in all foreign languages as well, including those in which no such word existed previously in any sense. Subdivision of the stress concept has become necessary as more recent work has led to such notions as 'eustress,' 'distress,' 'systemic stress' and 'local stress.' Confusion between stress as both an agent and a result can be avoided only by the distinction between 'stress' and 'stressor.' It is explained that the stress syndrome is—by definition—nonspecific in its causation. However, depending upon conditioning factors, which can selectively influence the reactivity of certain organs, the same stressor can elicit different manifestations in different individuals."

McC., Koizumi, K. et al., *The Life and Contributions of Walter Bradford Cannon 1871-1945*, pp. 89-107. Brooklyn, N.Y.: State University of New York Downstate Medical Center, 1975.

G88,048/75

The development of the stress concept in relation to homeostasis.

Selye, H.: "Homeostasis and heterostasis." In: Brooks, Ch. McC., Koizumi, K. et al., *The Life and Contributions of Walter Bradford Cannon 1871-1945*, pp. 108-112. Brooklyn, N.Y.: State University of New York Downstate Medical Center, 1975.

J4,297/75

Comparison of the concepts of homeostasis and heterostasis with special emphasis on W. B. Cannon's stimulating effect upon the author's work on adaptation.

GENERAL OUTLINE

Definition and Terminology of Biologic Stress

A great deal of confusion has arisen in lay and even in scientific literature because the term *stress* means different things to different people. Stress is part of our daily human experience, but it is associated with a great variety of essentially dissimilar problems, such as surgical trauma, burns, emotional arousal, mental or physical effort, fatigue, pain, fear, the need for concentration, the humiliation of frustration, the loss of blood, intoxication with drugs or environmental pollutants, or even with the kind of unexpected success that requires an individual to reformulate his lifestyle. Stress is present in the businessman under constant pressure; in the athlete straining to win a race; in the air-traffic controller who bears continuous responsibility for hundreds of lives; in the husband helplessly watching his wife's slow, painful death from cancer; in a race horse, its jockey and the spectator who bets on them. Medical research has shown that, while all these subjects face quite different problems, they respond with a stereotyped pattern of biochemical, functional and structural changes essentially involved in coping with any type of increased demand upon vital activity, particularly adaptation to new situations.

All endogenous or exogenous agents that make such demands are called *stressors*. Distinguishing between their widely differing specific effects and the common biologic response that they elicit is the key to a proper understanding of biologic stress.

From the point of view of its stressor activity, it is even immaterial whether the agent or situation being faced is pleasant or unpleasant; all that counts is the intensity of the demand for readjustment or adaptation that it creates. The mother who is suddenly told that her only son died in battle suffers a terrible mental shock; if years later, it turns out that the news was false and the son unexpectedly walks into her room alive and well, she experiences extreme joy. The specific results of the two events, sorrow and joy, are completely different, in fact they are opposite to each other, yet their stressor effect—the nonspecific demand for readjustment to a new situation—is the same.

It is difficult to see at first how such essentially different things as cold, heat, drugs, hormones, sorrow and joy could provoke an identical biologic reaction. Nevertheless

this is the case; it can now be demonstrated by highly objective, quantitative biochemical and morphologic parameters that certain reactions are totally nonspecific and common to all types of agents, whatever their superimposed specific effects may be.

The conceptual distinction between the specific and the nonspecific consequences of any demand made on the body was the most important step in the scientific analysis of stress phenomena.

Contrary to previously widely held opinion, stress is not identical to emotional arousal or nervous tension. It occurs in experimental animals even after total surgical deafferentation of the hypothalamus, which eliminates all neurogenic input. It can occur during anesthesia in man as well as in lower animals. It can occur even in plants, which have no nervous system. On the basis of these considerations. I recommend the following definition:

Stress is the nonspecific response of the body to any demand.

With regard to nonspecificity, the concept of stress is not without precedent. All machines, whether animate or inanimate, require energy for any of their activities, be these constructive or destructive. In fact, we shall see that biologic stress is closely linked to, though not identical with, energy utilization. This explains its apparently paradoxical, yet inseparable combination with the specific effects of the particular agent that creates a need for adaptive work. Any demand made on the body must be for some particular, that is, specific activity and yet is inseparably associated with non-specific phenomena (that is, energy utilization), just as in the inanimate world specific demands made upon machines to increase or decrease room temperature, to produce light or sound, to accelerate or decrease motion are invariably dependent upon energy utilization.

Therefore, stress is not something to be avoided. Indeed, it cannot be avoided, since just staying alive creates some demand for life-maintaining energy. Even while man is asleep, his heart, respiratory apparatus, digestive tract, nervous system and other organs must continue to function. Complete freedom from stress can be expected only after death.

However, in everyday life we must distinguish between two types of stress effects, namely, *eustress* (from the Greek *eu* or good—as in euphony, euphoria, eulogy) and *distress* (from the Latin *dis* or bad—as in dissonance, disease, dissatisfaction). Depending upon conditions, stress is associated with desirable or undesirable effects.

In view of these considerations it is also quite obvious that there cannot be *different types of stress*, although the effects of stressors are almost invariably different. There is no “specific stress”; this expression is a contradiction in terms. Such terms as emotional stress, surgical stress, flying stress, failure stress, cold stress, sleep deprivation stress, gravitational stress, swimming stress, social stress, and so on are acceptable only if we clearly understand that they are mere abbreviations for the stress produced by this or that factor.

In order to avoid confusion with various misuses of the term “stress” for specific disturbances caused by overexertion of specific organs or biochemical systems, it has been suggested by Lennart Levi and accepted by others to speak of “stress (Selye)” when using the term in my sense. However, since in biology and medicine stress was defined as “the nonspecific response of the body to any demand,” the parenthetical explanatory remark would be necessary only for those who do not accept this generally used definition. Instead of this flattering, but somewhat undeserved eponymous designation for a concept in whose elaboration hundreds of investigators participated,

I would suggest that they might refer to "nonspecific stress." This, I believe, is what everybody means by "stress (Selye)," since nonspecific was the key word in my original definition of the phenomenon. Yet to me it seems redundant to add nonspecific since this is implied in my definition; whenever the word stress is used in this treatise it refers to nonspecific responses only. In fact, unless otherwise stated, it is used for systemic nonspecific reactions (systemic stress), others being clearly characterized as topical or local stress. Of course, in this sense topical does not necessarily mean any particular region of the body but instead refers to specific demands primarily affecting one system of an organism (such as emotional arousal, intellectual effort, muscular work or response to hemorrhage).

Definition of Biologic Stress in General

(See also our earlier stress monographs, p. xiii)

Selye, H.: "The alarm reaction." In: Piersol, G. M. and Bortz, E. L., *The Cyclo-pedia of Medicine, Surgery and Specialities*, Vol. 15, pp. 15-38. Philadelphia: F A Davis, 1940. A8,048/40

The alarm reaction is defined as "the sum of all biological phenomena elicited by sudden exposure to stimuli to which the organism is, quantitatively or qualitatively, not adapted."

Freeman, G. L.: "Suggestions for a standardized 'stress' test." *J. Gen. Psychol.* 32: 3-11 (1945). 35,101/45

The author is "careful to define stress in terms of bodily arousal in a social situation, where the individual is placed on the defensive and deliberately confused as to his progress toward a desired success."

Beier, E. G.: "The effect of induced anxiety on flexibility of intellectual functioning." *Psychol. Monogr.* 65: 1-26 (1951). D92,619/51

"For the purpose of this study 'stress' is defined as the perception of threat, with resulting anxiety."

Janis, I. L.: *Air War and Emotional Stress. Psychological Studies of Bombing and Civilian Defense*, p. 280. New York, Toronto and London: McGraw-Hill, 1951. E4,323/51

Monograph on the psychologic consequences of bombing in Hiroshima and Nagasaki, and of air war in general and civil defense. [No reference is made to the stress concept in medicine, and such terms as adrenal, adrenaline, corticoids, hypothalamus or adaptation syndrome are not even mentioned in the index. The word stress appears to be used as a synonym for mental

upset but it is nowhere defined, although it is in the title of the book (H.S.).]

Pronko, N. H., Leith, W. R.: "Behavior under stress: a study of its disintegration." *Psychol. Rep.* 2: 205-222 (1956).

B28,732/56

The term stress is "considered as synonymous with such setting factors as are related to the disintegration of the behavioral response configuration of the organism."

Selye, H.: *The Stress of Life*, p. 324. New York, Toronto and London: McGraw-Hill, 1956; 2nd ed., 1975. C19,000/56

Stress is defined as "the state manifested by the specific syndrome which consists of all the nonspecifically induced changes within a biologic system. Thus stress has its own characteristic form, but no particular specific cause." Other simpler but less precise definitions suggested are: "the sum of all non-specific changes caused by function or damage," or "the rate of wear and tear in the body."

Lazarus, R. S., Baker, R. W., Broverman, D. M., Mayer, J.: "Personality and psychological stress." *J. Pers.* 25: 559-577 (1957). B29,451/57

"By stressor conditions... we mean those experimental conditions which are designed by an experimenter to be stressful, but which are not necessarily responded to or perceived as such by the subject. We reserve the term stress to refer to a state of the organism rather than the circumstances to which the individual is exposed."

Selye, H.: "Perspectives in stress research." *Perspect. Biol. Med.* 2: 403-416 (1959). C60,261/59

"For working purposes we may say that stress is a state manifested by a specific syndrome which consists of all the non-

specifically induced changes in a biologic system."

Richter, D.: "Some current usages of the word 'stress' in different fields." In: Tanner, J. M., *Stress and Psychiatric Disorder*, pp. 31-33. Oxford: Blackwell, 1960.

J13,501/60

Engel, G. L.: "A unified concept of health and disease." *Perspect. Biol. Med.* **3**: 459-485 (1960). J12,716/60

Because "by definition we specify that psychological stress involves, first, the mental apparatus, we can also say that the first response to a psychological stress, whether it be primary or secondary, will be psychological and/or behavioral."

Wolff, H. G.: "Stressors as a cause of disease in man." In: Tanner, J. M., *Stress and Psychiatric Disorder*, pp. 17-31. Oxford: Blackwell, 1960. C90,493/60

Stress is defined as "that state within a living creature which results from the interaction of the organism with noxious stimuli or circumstances."

Haward, L. R. C.: "The subjective meaning of stress." *Br. J. Psychol.* **33**: 185-194 (1960). C99,584/60

Theoretical considerations concerning "the subjective meaning of stress" as defined by various authors.

Wolf, S.: "Stress and heart disease." *Mod. Concepts Cardiovasc. Dis.* **29**: 599-604 (1960). G62,498/60

"Stress, for the purpose of this discussion, is present when the adaptive mechanisms of the living organism, in this instance man, are taxed or strained. The results are by no means specific. In fact, the variability of response of the human being may be immense, varying from invention or artistic creation, on the one hand, to surrender or death on the other."

Winokur, G., Stern, J. A., Graham, D. T.: "Stress as an inhibitor of pathological processes." *Psychiatr. Res. Rep. APA* **12**: 73-80 (1960). J11,150/60

Definition of stress as "an occasionally beneficial and a sometimes deleterious force working on the organism."

Pickering, G.: "Language: the lost tool of learning in medicine and science." *Lancet* July 15, 1961, pp. 115-119. D10,655/61

A very formal and scholarly discourse on correct language in science which, curiously,

comes to the conclusion that "the modern use of the word stress we owe to Selye, who used it to express the first stage in the common reaction of the mammal to a variety of harmful environmental changes." [Did I? (H.S.)]

Dohrenwend, B. P.: "The social psychological nature of stress: a framework for causal inquiry." *J. Abnorm. Soc. Psychol.* **62**: 294-302 (1961). D15,127/61

"Stress is a state intervening between antecedent constraint and consequent efforts to reduce constraint." Admittedly, this definition refers only to "stressors that are primarily social in nature and do not involve direct and immediate physical harm to the individual."

Mechanic, D., Volkart, E. H.: "Stress, illness behavior, and the sick role." *Am. Sociol. Rev.* **26**: 51-58 (1961). J10,611/61

At least in the behavioral sciences the term stress "seems to signify a state of affairs characterized by anxiety, discomfort, emotional tension, and difficulty in adjustment.... In the present study, stress was operationally defined as the subject's report of the frequency with which he was bothered by 'loneliness' and 'nervousness.'"

Torrance, E. P.: "A theory of leadership and interpersonal behavior under stress." In: Petrullo, L. and Bass, B. M., *Leadership and Interpersonal Behavior*, pp. 100-117. New York: Holt, Rinehart and Winston, 1961.

J10,652/61

"The distinctive element in stress is to be found in the lack of structure or loss of anchor in reality experienced by the individual or group as a result of the condition labeled 'stressful.' In the group situation, this lack of structure or loss of anchor in reality makes it difficult or impossible for the group to cope with the requirements of the situation, and the problem of leadership and interpersonal behavior becomes one of evolving or supplying a structure or anchor and of supplying the expertise for coping with the demands of the situation."

Daure, M.: "Thérapeutique rhino-stressante (rhino-stress)" (Rhino-stress therapeutics). *Bull. Acad. Nat. Méd. (Paris)* **145**: 28-34 (1961). D1,159/61

Rhino-stress is defined as stress produced by stimulating the nasal membranes, a technique which allegedly has considerable therapeutic value.

Mechanic, D.: *Students Under Stress. A Study in the Social Psychology of Adaptation*, p. 231. Glencoe, Ill.: Free Press, 1962.

E10,421/62

"We will define stress as the discomforting responses of persons in particular situations."

Fessel, W. J.: "Mental stress, blood proteins, and the hypothalamus." *Arch. Gen. Psychiatry* 7: 427-435 (1962). D69,380/62

"The word stress is used according to Selye's definition: Stress is a non-specific deviation from the normal resting state; it is caused by function or damage and it stimulates repair."

Lazarus, R. S., Speisman, J. C., Mordkoff, A. M., Davison, L. A.: "A laboratory study of psychological stress produced by a motion picture film." *Psychol. Monogr.* 76: 1-35 (1962).

J11,289/62

"In spite of persistent confusion about the precise meaning of the term, stress is widely recognized as a central problem in human life. Scientists of many disciplines have conceptualized stress but each field appears to have something different in mind concerning its meaning. For the sociologist, it is social disequilibrium, that is, disturbances in the social structure within which people live. Engineers conceive of stress as some external force which produces strain in the physical materials exposed to it. Physiologists deal with physical stressors that include a wide range of stimulus conditions which are noxious to the tissue systems of the body.... In the history of psychological stress research, there has been no clear separation between physical stressors which attack biological tissue systems and psychological stressors which produce their effects purely because of their psychological significance."

Pearson, H. E. S., Joseph, J.: "Stress and occlusive coronary-artery disease." *Lancet* February 23, 1963, pp. 415-418.

D57,816/63

Confusion about usage of the word stress is due to the fact that it has a double derivation: "on the one hand it is derived from the Latin *stringere*, to draw tight, with its implication of a constraining force; and, on the other, as an aphetic form of 'distress,' which in its descent from the old French *destrece* and late Latin *districtus* has come to mean hardship or affliction, as of one who is 'pulled asunder.'"

Burns, N. M., Chambers, R. M., Hendler,

E. (eds.): *Unusual Environments and Human Behavior. Physiological and Psychological Problems of Man in Space*, p. 438. Glencoe, Ill.: Free Press, 1963.

E10,423/63

In the preface it is stated, "stress represents a special aspect of the relationships man establishes between himself and his environment."

Ruff, G. E.: "Psychological and psychophysiological indices of stress." In: Burns, N. M., Chambers, R. M. et al., *Unusual Environments and Human Behavior*, pp. 33-59. Glencoe, Ill.: Free Press, 1963. E10,425/63

"The term stress usually implies a change in the conditions affecting an organism but requires an expenditure of effort so that the essential functions are maintained at the desired level."

Weybrew, B. B.: "Psychological problems of prolonged marine submergence." In: Burns, N. M., Chambers, R. M. et al., *Unusual Environments and Human Behavior*, pp. 87-125. Glencoe, Ill.: Free Press, 1963.

E10,427/63

"Borrowed from physics, 'stress,' as applied to submarine psychology, has the connotation of 2 or more forces in opposition. One of these forces is motivational, resulting in goal-directed activity, and the other an immediately perceived or anticipated barrier to this activity."

"For this paper stress is broadly defined as any stimulus or stimuli, experienced consciously or unconsciously, which is potentially harmful or threatening to the individual."

Weitz, J.: *Stress*. Research paper IDA/HQ 66-4672, pp. 251-294. Washington, D.C.: Inst. Defense Analyses, Research and Engineering Support Div., 1966.

J13,888/66

Review of stress research, particularly in relation to military medicine, with a section criticizing various currently used definitions of the term stress (16 refs.).

Back, K. W., Bogdonoff, M. D.: "Buffer conditions in experimental stress." *Behav. Sci.* 12: 384-390 (1967).

J9,369/67

"The organism experiences stress when it

faces problems which may constitute a threat."

Dohrenwend, B. P.: "Toward the development of theoretical models: I." *Milbank Mem. Fed. Q.* **45** No. 2, Part 2: 155-162 (1967). J10,926/67

The word stress is derived from constraint. "Stress is viewed as a state of the individual intervening between strong antecedent constraint (of whatever type) and consequent efforts to reduce the constraint. In this social psychological view, as in Selye's formulation of the stress response in physical and chemical terms that influenced it, stress is seen as underlying both adaptive and maladaptive behavior."

Yates, F. E.: "Physiological control of adrenal cortical hormone secretion." In: Eisenstein, A. B., *The Adrenal Cortex*, pp. 133-183. Boston: Little, Brown, 1967.

E6,888/67

"The term stress itself is here defined as any stimulus that will provoke simultaneous increases in plasma glucocorticoid concentration and in glucocorticoid secretion rates. This definition specifically excludes increases in ACTH release (and glucocorticoid secretion rates) that may follow decreases in plasma glucocorticoid concentrations from consideration as stress responses."

Levine, S., Scotch, N. A.: "Toward the development of theoretical models: II." *Milbank Mem. Fed. Q.* **45** No. 2, Part 2: 163-174 (1967). J10,927/67

"Life stress has been defined in terms of the degree to which the individual has experienced the following: blockage of occupational goals, job dissatisfaction, marital dissatisfaction, medical problems including hospitalizations and operations of family members, financial difficulties, service in the armed forces, including combat, and undesirable living accommodations."

Fraser, T. M.: "Men under stress." *Sci. Technol.* No. 73: 38-44; 82 (1968).

F98,050/68

Semipopular review on men under stress with special reference to environmental factors.

Klausner, S. Z.: *Why Man Takes Chances. Studies in Stress-seeking*, p. 267. Garden City, N.Y.: Doubleday, 1968. E10,636/68

Study of people who deliberately seek stress in the form of adventure, excitement, challenge and opportunity worthy of their

steel and who enjoy it. The author uses the term eustress.

Rasmussen, A. F. Jr.: "Emotions and immunity." *Ann. N.Y. Acad. Sci.* **164**: 458-462 (1969). H19,304/69

"'Stress' and 'stressor' are used interchangeably, as defined by Dr. Friedman and his associates elsewhere in this monograph." [This statement is cited only to show that even in 1969 the importance of distinguishing cause and effect in this field had not been generally recognized (H.S.).]

Holst, D. von: "Sozialer Stress bei Tupajas (*Tupaia belangeri*). Die Aktivierung des sympathischen Nervensystems und ihre Beziehung zu hormonal ausgelösten ethologischen und physiologischen Veränderungen" (Social stress in the tree shrew [*Tupaia belangeri*]. The activation of the sympathetic nervous system and its correlation with hormonally produced ethologic and physiologic phenomena). *Z. Vergl. Physiol.* **63**: 1-58 (1969). G90,282/69

"The term stress always refers to the state of the organism under the influence of a damaging agent (stressor)."

McGrath, J. E.: "A conceptual formulation for research on stress." In: McGrath, J. E., *Social and Psychological Factors in Stress*, pp. 10-21. New York, Chicago and San Francisco: Holt, Rinehart and Winston, 1970.

E10,314/70

General discussion of various definitions of stress based on the provocative situation, the organism's response, the organism-environment transaction or engineering analogies. No preferred definition is formulated.

Kahn, R. L.: "Some propositions toward a researchable conceptualization of stress." In: McGrath, J. E., *Social and Psychological Factors in Stress*, pp. 97-103. New York, Chicago and San Francisco: Holt, Rinehart and Winston, 1970.

E10,318/70

In this short address on how research on stress could be logically organized and clearly defined, the author states that "my preference is to call the demand in the external environment 'stress,' and the received demand 'strain' or 'not strain.'"

Weick, K. E.: "The 'ess' in stress: some conceptual and methodological problems." In: McGrath, J. E., *Social and Psychological Factors in Stress*, pp. 287-347. New York,

Chicago and San Francisco: Holt, Rinehart and Winston, 1970. E10,328/70

Extensive lecture on the semantics of the term stress and its relation to the methodology of studying the phenomenon.

Bailit, H. L., Workman, P. L., Niswander, J. D., MacLean, C. J.: "Dental assymmetry as an indicator of genetic and environmental conditions in human populations." *Hum. Biol.* **42**: 626-638 (1970). J20,565/70

Dental assymmetry may occur in various human populations as a consequence of genetic or environmental stress factors. "Genetic stress may result from inbreeding due to the finite size of the population or to a mating pattern involving consanguinity. This can lead to a reduction in population fitness because of the exposure of deleterious recessive genes in a homozygous state or, more importantly, because of a breakdown in the coadaptation of the genetic system. Indications of inbreeding stress are provided by estimates of the inbreeding coefficient, the effective population size, the amount of gene flow into the population, or by a comparison of the genetic variance of different quantitative characters with that observed in large random mating populations. Another genetic stress may result from a drastic diminution in population size, leaving too little genetic variation to adapt to a changing or extremely heterogeneous environment."

Sells, S. B.: "On the nature of stress." In: McGrath, J. E., *Social and Psychological Factors in Stress*, pp. 134-139. New York, Chicago and San Francisco: Holt, Rinehart and Winston, 1970. E10,321/70

The author proposes to define stress as follows: "The individual is called upon in a situation to respond to circumstances for which he has no adequate response available. The unavailability of an adequate response may be due to physical inadequacy; absence of the response in the individual's response repertoire; lack of training, equipment, or opportunity to prepare. The consequences of failure to respond effectively are important to the individual. Personal involvement in situations can be defined in terms of importance of consequences to the individual."

Parrot, J.: "The measurement of stress and strain." In: Singleton, W. T., Fox, J. G. et al., *Measurement of Man at Work. An Appraisal of Physiological and Psychological Criteria in Man-Machine Systems*, pp. 27-33. London: Taylor and Francis, 1971. J18,094/71

"A stimulus constitutes a stress for a particular system if a strain ensues within that system. In other words, under some threshold, a given factor may be a stress only for those individuals in whom it results in strain."

Levi, L. (ed.): *Society, Stress and Disease*, p. 485. New York, Toronto and London: Oxford University Press, 1971. E9,300/71

International Interdisciplinary Symposium, sponsored by the University of Uppsala and the WHO, at which specialists in many disciplines discussed the definition: "biologic stress is the nonspecific response of the body to any demand made upon it."

"Society, stress and disease." *WHO Chron.* **25**: 168-178 (1971). G85,103/71

Stress is defined as "the pattern of physiological reactions that prepares an organism for action." [The author of this definition is not identified, nor is it stated why the characteristic nonspecificity of the response and the teleonomically useless manifestations of shock due to overwhelming injury are not included (H.S.).]

Mason, J. W.: "A re-evaluation of the concept of 'nonspecificity' in stress theory." *J. Psychiatr. Res.* **8**: 323-333 (1971).

G86,484/71

Brief but excellent analysis of the evidence contradicting Selye's definition of stress. Mason states that stress "may simply be the psychological apparatus involved in emotional or arousal reactions to threatening or unpleasant factors in the life situation as a whole."

Levi, L.: "Definition and evaluation of stress." *Rep. Lab. Clin. Stress Res.* (Stockholm) No. 25: 1-11 (1971). G87,068/71

Review of the hormonal, nervous and cardiovascular indices of stress which is defined as "the nonspecific response of the body to any demand made upon it."

McLean, A.: "Occupational 'stress.' A misnomer." *Occup. Ment. Health* **2** No. 4: 12-15 (1972). J15,754/72

The author concludes that "if we were to use the word stress to refer, say, only to Selye's adaptation syndrome, then its meaning would be restricted entirely to physiological stress reaction to stressor and in fact to an even narrower concept: namely the non-specific responsive tissues." [This shows a complete misunderstanding of the concept of "local stress" (which may selectively af-

fect, say, the nervous system). Hence it eliminates the key characteristic, nonspecificity, from the definition of stress (H.S.).]

Wardwell, W. I.: "A study of stress and coronary heart disease in an urban population." *Bull. N.Y. Acad. Med.* **49**: 521-531 (1973). J3,167/73

Discussion of seven definitions of stress, illustrating how meaningless the term is unless we restrict it to an internationally acceptable, clearly formulated concept.

Dohrenwend, B. S.: "Life events as stressors: a methodological inquiry." *J. Health Soc. Behav.* **14**: 167-175 (1973).

J16,337/73

On the basis of extensive statistical studies using questionnaires, the author concludes that "stressfulness is better conceived as life change than as undesirability of life events."

Ewbank, R.: "Use and abuse of the term 'stress' in husbandry and welfare." *Vet. Rec.* **92**: 709-710 (1973). J5,520/73

"A strong case can be made to revert (with modifications) to Selye's original terminology and to restrict the use of the term stress to the mechanisms by which an animal resists the effects of adverse stimuli. The mechanism will include all the means by which an animal attempts to adapt, and not just the C.N.S. pituitary adrenal pathway." Both excessive and insufficient degrees of stress are harmful.

Bugard, P.: *Stress, Fatigue et Dépression. L'Homme et les Agressions de la Vie Quotidienne* (Stress, fatigue and depression. Man and the aggression of everyday life), Vol. 1, p. 294; Vol. 2, p. 302. Paris: Doin Edit., 1974. E10,487/74

Stress simultaneously reflects both the pressure of a given environment and man's reaction to this pressure.

Aakster, C. W.: "Psycho-social stress and health disturbances." *Soc. Sci. Med.* **8**: 77-90 (1974). J10,857/74

"Stress is any environmental force which leads (or is expected to lead) to disequilibrium upon one or more of the essential variables of the system. Stress, therefore, always points to a relationship between system and environment. Well-known types of stress are conflicting expectations, goal-means conflict, overload, underload, deprivation, incapacity, trauma, perceived threats, etc."

Mason, J. W.: "A historical view of the

'stress' field. Part I." *J. Hum. Stress* **1** No. 1: 6-12 (1975). H97,891/75

Mason, J. W.: "A historical view of the 'stress' field Part II." *J. Hum. Stress* **1** No. 2: 22-36 (1975). H97,892/75

Review of the evolution of the stress concept from Cannon's work on the emergency discharge of EP during fight-or-flight reactions up to present day views on the importance of the hypothalamus-pituitary-adrenocortical system, the triphasic nature of the G.A.S., and the nonspecific stereotyped response pattern of the body to any demand. Eustress is not discussed, but the author emphasizes that, "of all the known responses of higher organisms, emotional arousal is certainly one of the most ubiquitous or relatively 'nonspecific' reactions common to a great diversity of situations." On the other hand, he clearly recognizes that "this is not to conclude that the pituitary-adrenal cortical system responds only to psychological stimuli." In accordance with earlier work on the effect of internal and external conditioning factors upon the resulting reaction form, it is agreed that the reaction could not be absolutely nonspecific, even if it occurred after any demand (48 refs.).

Selye, H.: "Confusion and controversy in the stress field." *J. Hum. Stress* **1** No. 2: 37-44 (1975). J4,295/75

Answer to the preceding articles. "The continued use of the word stress as a non-specific response to any demand is deemed most desirable. The once vague term can now be applied in a well-defined sense and is accepted in all foreign languages as well, including those in which no such word existed previously in any sense. Subdivision of the stress concept has become necessary as more recent work has led to such notions as 'eustress,' 'distress,' 'systemic stress' and 'local stress.' Confusion between stress as both an agent and a result can be avoided only by the distinction between 'stress' and 'stressor.' It is explained that the stress syndrome is—by definition—nonspecific in its causation. However, depending upon conditioning factors, which can selectively influence the reactivity of certain organs, the same stressor can elicit different manifestations in different individuals."

Selye, H.: "Homeostasis and heterostasis." In: Brooks, Ch.McC., Koizumi, K. et al., *The Life and Contributions of Walter Bradford Cannon 1871-1945*, pp. 108-112. Brook-

lyn, N.Y.: State University of New York Downstate Medical Center, 1975.

J4,297/75

Comparison of the concepts of homeostasis and heterostasis with special emphasis on W. B. Cannon's stimulating effect upon the author's work on adaptation.

greater degrees of specificity and sensitivity. Its successive nonadapted, adapted, and non-adapted stages, associated with increasing sensitization, probably involve similar endocrine and electrolyte mechanisms." Here, the alarm reaction is followed by addiction with high degrees of specific sensitivity. [The concept is not clearly defined (H.S.).]

Fox, H. M., Gifford, S., Murawski, B. J., Rizzo, N. D., Kudarauskas, E. N.: "Some methods of observing humans under stress." *Psychiatr. Res. Rep. APA*. 7: 14-26 (1957).

J11,149/57

"Psychological stress results from any external threat, from any intensification of the biological drives, or from any increased demand from the conscience which challenges the capacity of the individual to maintain a balance between his needs and his satisfactions."

Caron, A. J., Wallach, M. A.: "Personality determinants of repressive and obsessive reactions to failure-stress." *J. Abnorm. Soc. Psychol.* 59: 236-245 (1959). G82,249/59

The psychologic results of failure are ascribed to "failure-stress."

Randolph, T. G.: "Human ecology and susceptibility to the chemical environment." *Ann. Allergy* 19: 518-540; 657-677; 779-799; 908-929 (1961). D5,214/61

Extensive review on the chemical environment's influence upon resistance, with a section on stress. The author creates the concept of the specific adaptation syndrome, defined as "a clinical counterpart of Selye's general adaptation syndrome." [It is not clear how specific adaptation to each agent can result in a single, stereotyped syndrome (H.S.).]

Cambrelin, G.: "Reflexions sur le 'stress'" (Reflections on stress). *Acta Otolaryngol. (Stockh.)* 53: 259-260 (1961). D21,485/61

Semantic considerations lead the author to state that the English word stress should not be translated into French as *agression* but as *alerte, alarme, choc* or *tension*.

Ball, W. A.: "Anti-stress." *Practitioner* 190: 781-785 (1963). E20,610/63

According to the author, "Selye in his stress syndrome has given us a description of the part that stress or strain plays in the causation of ill health, and a new point of attack." For the opposite of this, the term anti-stress is suggested. [Apparently, the au-

Are There Different Types of Stress?

(See also our earlier stress monographs, p. xiii)

Symonds, C. P.: "The human response to flying stress. Lecture I: Neurosis in flying personnel." *Br. Med. J.* December 4, 1943, pp. 703-706; "Lecture II: The foundations of confidence." *Br. Med. J.* December 11, 1943, pp. 740-744. B26,422/43

The objection to the use of flying stress as a clinical diagnosis is the same one that applies to the terms aeroneurosis or aviator's neurasthenia. The term flying stress "should be used only to denote the load which aircrews have to carry."

Symonds, C. P.: "Use and abuse of the term flying stress." In: Air Ministry, *Psychological Disorders in Flying Personnel of the Royal Air Force, Investigated during the War, 1939-1945*, pp. 18-21. London: H M SO, 1947. B76,340/47

"It should be understood once and for all that flying stress is that which happens to the man, not that which happens in him: it is a set of causes, not a set of symptoms."

G86,484/71

Brief but excellent analysis of evidence contradicting Selye's definition of stress. Mason states that stress "may simply be the psychological apparatus involved in emotional or arousal reactions to threatening or unpleasant factors in the life situation as a whole."

Holmes, D. J.: *Psychotherapy: Experience, Behavior, Mentation, Communication, Culture, Sexuality, and Clinical Practice*, p. 1077, sect. 1-6. Boston: Little, Brown, 1972.

E10,304/72

A voluminous yet very readable treatise on psychotherapy in which we counted fourteen pages that refer specifically to stress without defining the sense in which the author uses the term. We were unable to locate in the subject index any reference to the hypophysis, the hypothalamus, the limbic system or the role played by corticoids or catecholamines.

Tsukiyama, H., Otsuka, K., Kyuno, S., Fujishima, S., Kijima, F.: "Influence of immobilization stress on blood pressure, plasma renin activity and biosynthesis of adrenocorticoid." *Jap. Circ. J.* **37**: 1265-1270 (1973). H81,677/73

In rabbits, "shortly after the beginning of immobilization stress a remarkable elevation in the arterial pressure, a significant increase in plasma renin levels and plasma corticosterone concentrations were observed." However, the changes in plasma renin and corticosterone did not run parallel; hence, there appear to be different mechanisms activating the renin-angiotensin and pituitary-adrenocortical systems. EEG studies suggest that

the homeostatic mechanisms mediated by the mesencephalic reticular formation and grey matter regulate blood pressure and renin release while the hippocampus, amygdala and anterior hypothalamic area are less effective in this respect. Findings derived from selective electric stimulation of various brain areas are in accordance with this interpretation.

Lát, J.: "Methodological problems of hormone-behaviour relations during stress." In: Németh, Š.; *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 245-254. Bratislava: Slovak Academy of Sciences, 1973. E10,472/73

Theoretical considerations concerning the relative nonspecificity of stress reactions owing to superimposed specific effects of stressors. "A drug or hormone may have a nonspecific effect upon behaviour and at the same time a very specific effect upon some CNS structures which in turn exert a non-specific effect upon behaviour."

Forgács, P.: "Gravitational stress in lung disease." *Br. J. Dis. Chest* **68**: 1-10 (1974).

J10,403/74

The effects of acceleration are described and termed gravitational stress.

Wilkins, W. L.: "Social stress and illness in industrial society." In: Gunderson, E.K.E. and Rahe, R. H., *Life Stress and Illness*, pp. 242-254. Springfield, Ill.: Charles C Thomas, 1974. E10,694/74

Discussion of the various definitions of stress. Special attention is given to "stress (Selye)" but no definite recommendation is made (12 refs.).

Definition of Diseases of Adaptation

(See also our earlier stress monographs, p. xiii)

Godin, O., Blondiau, P., Lauwers, P., Gonze, A.: "La pathergie à l'humidité. Etude hydrogéologique de la région bruxelloise" (Pathergy in humidity. A hydrogeologic study of the Brussels region). *Acta Otorhinolaryngol. Belg.* **26**: 387-460 (1972). G99,747/72

While allergy is a hypersensitivity to chemicals, pathergy is defined as a comparable response to physical agents and considered to represent diseases of adaptation.

Principal Pathways Mediating the Response to a Stressor

The pathways through which the stress response is mediated are extremely complex and will be analyzed in depth later along with the pertinent literature. To gain perspective it may be useful to start with an overview; this will facilitate the task of the reader who is interested only in looking up a specific point but must nevertheless know exactly where it fits into the complicated network of interacting events that are triggered by confrontation with a stressor. In this presentation I shall follow the schematic outline given in Figure 2.

Apart from specific changes (which need not be discussed here), the first effect of a *stressor* acting upon the body, is to produce a nonspecific stimulus. This may be a nervous impulse, a chemical substance or lack of an indispensable metabolic factor, and it is referred to simply as the *first mediator* because we know nothing about its nature. We are not even certain that it has to be an excess or deficiency of any particular substance; it is possible that various derangements of homeostasis can initiate the stress response. Undoubtedly in man, with his highly developed central nervous system (CNS), emotional arousal is one of the most frequent initiators of somatic stress; yet it cannot be regarded as the only factor capable of causing stress, since stress reactions (that is, nonspecific responses common to all demands made upon a living organism) also occur in the most primitive animals in the absence of a nervous system. But even in man conscious psychic disturbances are not indispensable, since typical stress reactions can occur in patients exposed to stressors (for example, trauma, hemorrhage) while under deep anesthesia. Indeed, anesthetics themselves (for example, ether) are commonly used in experimental medicine to produce stress, and "the stress of anesthesia" is a serious problem in clinical surgery.

(For a detailed diagram of the common pathways mediating the stress response itself, see p. 25.)

When an *agent* acts upon the body (thick outer frame of the diagram) the effect will depend upon three factors (broad vertical arrows pointing to the upper horizontal border of the frame). All agents possess both nonspecific *stressor* effects (solid part of arrow) and *specific* properties (grey part of arrow). The latter are variable and characteristic of each individual agent; they will not be discussed here other than to state that they are inseparably attached to the stressor effect and invariably modify it. The other two heavy vertical arrows, pointing toward the upper border of the frame, represent exogenous and endogenous *conditioning factors* that largely determine the reactivity of the body. It is clear that since all stressors have some specific effects, they cannot elicit exactly the same response in all organs; furthermore, even the same agent will act differently on different individuals, depending upon the internal and external conditioning factors that determine their reactivity.

Although we have still to identify the first mediator(s), we do know that eventually stress acts upon the *hypothalamus* and particularly the ME. This action appears to be regulated largely by means of (mediated through or modified by) nervous stimuli coming from the cerebral cortex, the reticular formation and the limbic system (especially the hippocampus and amygdala).

The incoming nervous stimuli reach certain *neuroendocrine cells*, most of which are located in the ME. These act as "transducers," transforming nervous signals into a humoral messenger, the *corticotropin hormone-releasing factor (CRF)*, which can be demonstrated histochemically in the ME region and can also be extracted from it. Oddly enough, the posterior pituitary contains the highest concentration of CRF, and

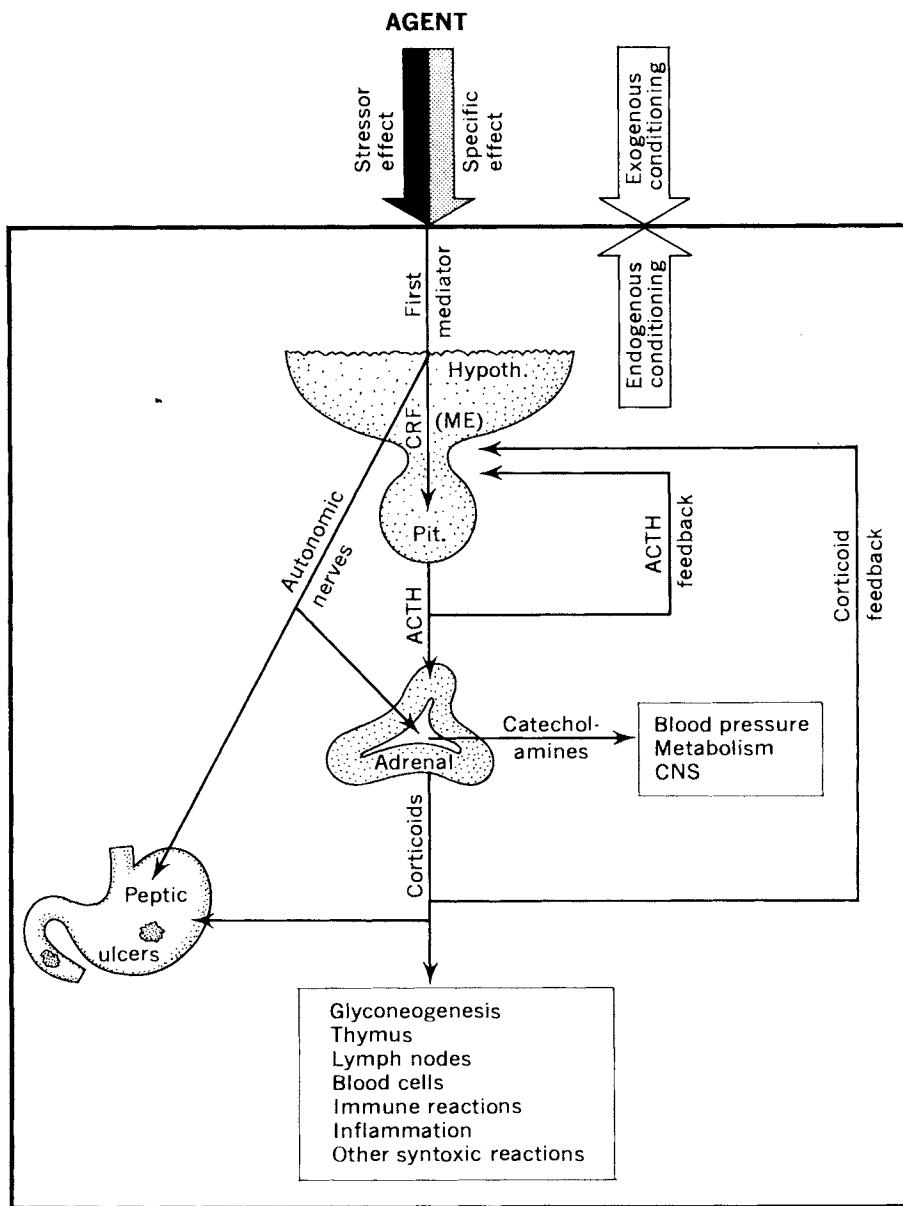

Figure 2. Principal pathways mediating the response to a stressor agent and the conditioning factors which modify its effect.

As soon as any *agent* acts upon the body (thick outer frame of the diagram) the resulting effect will depend upon three factors (broad vertical arrows pointing to the upper horizontal border of the frame). All agents possess both nonspecific *stressor* effects (solid part of arrow) and *specific* properties (grey part of arrow). The latter are variable and characteristic of each individual agent; they will not be discussed here other than to state that they are inseparably attached to the stressor effect and invariably modify it. The other two heavy vertical arrows, pointing toward the upper border of the frame, represent exogenous and endogenous *conditioning factors* which largely determine the reactivity of the body. It is clear that since all stressors have some specific effects, they cannot elicit exactly the same response in all organs; furthermore, even the same agent will act differently in different individuals, depending upon the internal and external conditioning factors which determine their reactivity.

it has been isolated from this source in pure form, thus permitting the determination of its chemical formula as a polypeptide which subsequently was synthesized. Yet we have no absolute proof that the CRF-active material extracted from the hypothalamus is identical with that obtained from the posterior lobe since only the structure of the latter has been definitely ascertained. Although vasopressin (the antidiuretic hormone or ADH) possesses considerable CRF activity it is not identical with CRF; this has been shown by the well-documented differences in their chemical structure and physiologic activity.

CRF reaches the anterior lobe through the *hypothalamo-hypophyseal portal system* that originates in the ME region within a network of capillaries into which CRF is discharged by the local neuroendocrine cells. It is then carried down through the larger veins of the pituitary stalk to a second capillary plexus in the pituitary.

The hypothalamus does not stimulate the *adrenocorticotrophic hormone (ACTH)* secretion of the anterior lobe through nervous pathways descending in the pituitary stalk but rather through blood-borne substances carried by way of the portal veins. That is why transection of the stalk inhibits the ACTH secretion only before vascular connections between the hypothalamus and the gland are reestablished; if regeneration of these vessels is prevented by interposing a plate between the cut ends of the stalk, this pathway is permanently blocked.

Both *in vivo* and *in vitro* experiments have proven that CRF elicits a discharge of ACTH from the adenohypophysis into the general circulation. Upon reaching the adrenal cortex, it causes secretion of corticoids, mainly *glucocorticoids*, such as cortisol or corticosterone. These induce glycogenesis, thereby supplying a readily available source of energy for the adaptive reactions necessary to meet the demands made by the stressors. In addition, they facilitate various other enzymatically regulated adaptive metabolic responses and suppress immune reactions as well as inflammation, assisting the body to coexist with potential pathogens (syntoxic reactions). Furthermore, the glucocorticoids are responsible for the thymic lymphatic involution, eosinopenia and lymphopenia characteristic of acute stress. Curiously, glucocorticoids are needed for the acquisition of adaptation primarily during the alarm reaction, but not so much to maintain the adjustment during the stage of resistance. ACTH plays a comparatively minor role in the secretion of *mineralocorticoids*, such as aldosterone, which is regulated mainly by the renin-hypertensin system and the blood electrolytes, whose homeostasis is in turn influenced by them.

This chain of events is cybernetically controlled by several *biofeedback* mechanisms. Whether an excess of CRF can inhibit its own endogenous secretion is still doubtful because its lifespan in the circulating blood is very short. On the other hand, there is definite proof of an ACTH feedback (short-loop feedback) by a surplus of the hormone, which returns to the hypothalamo-pituitary system and inhibits further ACTH production. We have even more evidence to substantiate the existence of a corticoid feedback mechanism (long-loop feedback) in that a high blood corticoid level similarly inhibits ACTH secretion. It is still not quite clear to what extent these feedbacks act upon the neuroendocrine cells of the hypothalamus, the adenohypophysis or both (hence, in Figure 2 the corresponding arrowheads merely point towards the hypothalamo-hypophyseal region in general, without specifying exactly where their target areas are situated).

A second important pathway that mediates the stress response is carried through the *catecholamines* liberated under the influence of an acetylcholine discharge, at autonomic nerve endings and in the adrenal medulla. The chromaffin cells of the latter

secrete mainly EP, which is of considerable value in that it stimulates mechanisms of general utility to meet various demands for adaptation. Thus it provides readily available sources of energy by forming glucose from glycogen depots and free fatty acids from the triglyceride stores of adipose tissue; it also quickens the pulse, raises the blood pressure to improve circulation into the musculature, and stimulates the CNS. In addition, EP accelerates blood coagulation and thereby protects against excessive hemorrhage should wounds be sustained in conflicts. All of this is helpful in meeting the demands of fight or flight.

The pathogenesis of the *stress ulcers* in the duodenum and stomach is not yet fully understood, but apparently glucocorticoids and autonomic nerve impulses cooperate to produce these characteristic manifestations of the stress syndrome.

Conditioning

How can different agents cause the same response (namely, stress) and this stereotyped response produce different lesions in various patients?

After the general characteristics and pathways of the stress reaction were clarified, there still remained two apparently insurmountable obstacles to our formulation of the concept that the Local Adaptation Syndrome (L.A.S.) and its derailments are all fundamentally dependent upon a single stereotyped response to stress:

- (1) Qualitatively different agents of equal toxicity (or stressor potency) do not necessarily elicit exactly the same syndrome in different people.
- (2) Even the same degree of stress, induced by the same agent, may produce different lesions in different individuals.

It took many years to show that qualitatively different agents can cause the same effects. They differ only in their specific actions, while their nonspecific stressor effects (such as ACTH secretion or corticoid secretion and thymic lymphatic involution) are essentially the same, although these are usually modified by the superimposed specific effects of the evocative agents.

The fact that the same stressor can cause different lesions in different individuals has been traced to "conditioning factors" that can selectively enhance or inhibit one or the other stress effect. This conditioning may be endogenous (genetic predisposition, age or sex) or exogenous (treatment with certain hormones, drugs, or dietary factors) (see Figure 2). Under the influence of such conditioning factors, a normally well-tolerated degree of stress can become pathogenic and cause diseases of adaptation. It then selectively affects those parts of the body that are particularly sensitized both by these conditioning factors and by the specific effects of the eliciting agent. This selectivity of damage is comparable to that in different chains, in each of which mechanical stress of identical tension will break the particular link that has become weakest as a result of internal or external factors.

Degrees of Specificity, Relationship between the G.A.S. and L.A.S.

We have seen that every agent capable of producing systemic stress with the manifestations of the G.A.S. also has some specific actions that primarily affect individual target regions.

In the case of local trauma, this leads to the development of what we have called the *Local Adaptation Syndrome* (L.A.S.) in the form of cell degeneration, necrosis, inflammation, wound healing, and so on at the site of injury. The local stress stimuli emanating from the primarily afflicted region will, in proportion to their intensity, mobilize the hypothalamus-pituitary-adrenal mechanism and elicit systemic stress of varying degrees of severity. However, even if the target is not a small area but instead the cerebral cortex (in the case of emotional arousal), the general metabolism, or the reticuloendothelial system (RES), there is a primary topical response. This corresponds to the L.A.S. and is superimposed upon the G.A.S. produced by the resulting systemic manifestations. Conversely, this secondary G.A.S. influences the L.A.S. through neurohumoral mechanisms (for example, anti-inflammatory hormones). That is one reason why the specificity of any agent acting upon the organism is never absolute but varies in degree. Some stimuli (for example, a small local burn or the effect of green light upon the retina) have virtually only specific local effects, whereas others (for example, whole body x-irradiation, antimitotic drugs, extreme neuromuscular exhaustion) are primarily characterized by their systemic stress effect.

To summarize these important points, let me reemphasize that it is not correct to speak of nervous stress, cold stress, traumatic stress and so on, as if each of these produced a different type of stress. By definition, the stress response is nonspecific and thus is common to all these stressors. What differs is only the manifest result of exposure to a particular type of demand; the primary specific and circumscribed effects (corresponding to the L.A.S.) are inseparably superimposed upon the stereotyped systemic G.A.S. manifestations. Specificity is never absolute; it is always a matter of degree.

Cross Resistance and Treatment with Stressors or Stress-Hormones

Stress is not invariably harmful but may actually have prophylactic or curative value under certain conditions. Thus, pretreatment with one stressor may induce resistance to another by mobilizing the body's nonspecific adaptive system. For example, syntoxic hormones (glucocorticoids) liberated during systemic stress can protect against various excessive and harmful inflammatory or immune reactions. This principle has been applied clinically in the treatment of inflammatory diseases and the suppression of graft rejection. However, other forms of cross-resistance may depend upon different mechanisms.

Before we knew anything about the mechanism of stress reactions, nonspecific treatment had to rely entirely upon the exposure of patients to stressors (cold, heat, hydrotherapy, bloodletting, exercise, fever therapy, electroshock, and so on). It was not known how these agents acted, but there could be no doubt that in many cases they were beneficial. It is still not clear why some nonspecific therapeutic procedures are more valuable in certain diseases than in others, but probably their specific effects are superimposed on—in some cases, even more important than—their nonspecific actions. Undoubtedly, all these treatments do produce stress and often act through the liberation of stress hormones such as ACTH, corticoids and catecholamines. Whenever this is the case, it is of course much more acceptable to the patient to receive the hormones themselves, rather than to count on their "auto-pharmacologic" endogenous production by exposure of the patient to drastic types of nonspecific treatments (for example, shock therapy).

The Diseases of Adaptation or Stress Diseases

Those maladies in whose development the nonspecific stressor effects of the eliciting pathogen play a major role are called *diseases of adaptation* or *stress diseases*. However, just as there is no pure stressor (that is, an agent that causes only nonspecific responses and has no specific actions of its own), so there are no pure diseases of adaptation. Some nonspecific components participate in the pathogenesis of every malady, but no disease is due to stress alone. The justification for placing a malady in this category is directly proportional to the role that maladjustment to stress plays in its development.

In the main text section on the diseases of adaptation I shall discuss this point at length in connection with a great many pathologic conditions. Here, suffice it to point out that in some instances (for example, peptic ulcers, hypertension, surgical shock, certain neuropsychiatric derangements) stress may be far the most important pathogenic factor. However, in other cases (instantly lethal intoxications, traumatic injuries to the spinal cord, most congenital malformations) it plays little or no role, either because the damage is inflicted so rapidly that there is no time for any adaptive process, or because the pathogen is highly specific. In the latter event, whatever develops represents a secondary result and not the primary component of the pathogenic process.

In typical diseases of adaptation, insufficient, excessive or faulty reactions to stressors (for example, inappropriate hormonal or nervous responses) are at the root of the disturbance. Yet as I have said before, there is no disease that can be attributed exclusively to maladaptation, since the cause of nonspecific responses will always be modified by various "conditioning factors" that enhance, diminish, or otherwise alter disease proneness. Most important among these are the specific effects of the primary pathogen, and the factors influencing the body's reactivity by endogenous (heredity, previously sustained damage to certain organs) or by exogenous (concurrent exposure to other pathogens and environmental agents, diet) conditioners. Hence, the diseases of adaptation cannot be ascribed to any one pathogen but to "pathogenic constellations;" they belong to what we have called the *pluricausal diseases* ("multifactorial maladies") that depend upon the simultaneous effect of several potentially pathogenic factors, among which, sometimes, none alone would produce disease.

Syntoxic and Catatoxic Responses

During the second half of the nineteenth century—well before anyone thought of stress—Claude Bernard first pointed out clearly that the internal medium of the living organism is not merely a vehicle for carrying nourishment to cells but that "it is the fixity of the *milieu intérieur* which is the condition of free and independent life." Some fifty years later, Cannon suggested the designation *homeostasis* (from the Greek *homoios* or similar and *stasis* or position, standing) for "the coordinated physiological processes which maintain most of the steady states in the organism," that is, the ability to stay the same or static.

What is meant by the "fixity of the *milieu intérieur*"? Everything inside the skin and even the skin itself constitutes the internal medium. To maintain a healthy life, nothing within the body must be allowed to deviate far from the norm; if something does, the individual will become sick or even die. There are many complex biochemical

mechanisms that ensure the fixity and steadiness of the *milieu intérieur*. Let us look briefly at how they work.

The biochemical analysis of the stress syndrome showed that homeostasis depends mainly upon two types of reactions: *syntoxic* (from the Greek *syn* or together) and *catatotoxic* (from the Greek *cata* or against). Apparently, to resist different stressors the organism can regulate its own reactions through chemical messengers and nervous stimuli that either pacify or incite to fight. Syntoxic stimuli act as tissue tranquilizers, creating a state of passive tolerance that permits a kind of symbiosis, or peaceful coexistence, with aggressors. The catatotoxic agents cause chemical changes (mainly through the production of hepatic microsomal enzymes) that lead to an active attack upon the pathogen, usually by accelerating its metabolic degradation.

Presumably, in the course of evolution the body learned to defend itself against all kinds of aggressors (whether arising in the organism or the environment) through mechanisms that help it tolerate the aggressor (*syntoxic*) or destroy it (*catatoxic*). Among the most effective syntoxic hormones are the *glucocorticoids*.

It is not immediately evident why it should be advantageous to inhibit inflammation or interfere with the rejection of foreign tissues, since both phenomena are essentially useful defense reactions. The main purpose of inflammation is to localize irritants (for example, microbes) by putting a barricade of inflammatory tissue around them to prevent their spread into the blood, which could lead to sepsis and even death. The suppression of this basic defense reaction is an advantage, however, when a foreign agent is in itself innocuous and causes trouble only by inciting inflammation. In such cases, inflammation itself is what we experience as a disease. Thus, in many patients who suffer from hay fever or extreme inflammatory swelling after an insect sting, suppression of defensive inflammation is essentially a cure, because the invading stressor agent is not in itself dangerous or likely to spread and kill. In the case of grafts, it may even be lifesaving.

At this point it is useful to distinguish between direct and indirect pathogens. Direct pathogens cause disease regardless of the body's reaction, whereas indirect pathogens cause damage only because they provoke exaggerated defensive responses.

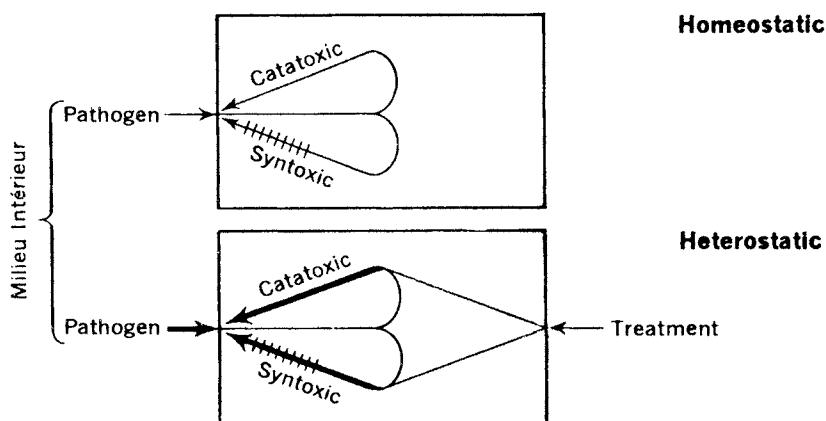

Figure 3. Comparison of homeostatic and heterostatic defense mechanisms (Reproduced from *Stress Without Distress*, Fig. 6, p. 56, 1974, by permission of the J B Lippincott Company).

If a man accidentally exposes his hand to a strong acid, alkali or boiling water, damage will occur regardless of his reactions, because these are all direct pathogens. They would damage even the hand of a dead man, who obviously could not put up any defense reactions. Most common inflammatory irritants, including allergens, are essentially indirect pathogens: they cause disease only through the purposeless defense reactions that they stimulate.

Immunologic reactions, which lead to the destruction of microbes, grafts and other foreign tissues, undoubtedly developed during evolution as useful defensive mechanisms against potentially dangerous foreign materials. When the attack against the foreign agent is unnecessary or even harmful—as in the case of many allergens, heart transplants, and so on—man can improve upon the wisdom of Nature by suppressing this hostility. When the aggressor is dangerous, the defensive reaction should not be suppressed but if possible increased beyond the normal level, which can be achieved, for example, by catatoxic substances that carry the chemical message to the tissues to destroy the invaders even more vigorously than would normally be the case.

The Concept of Heterostasis

Natural homeostatic mechanisms are usually sufficient to maintain a normal state of resistance; however, when the organism is faced with unusually heavy demands, ordinary homeostasis is not enough. The “thermostat of defense” must be raised to a heightened level. For this process, I proposed the term *heterostasis* (from the Greek *heteros* or other) as the establishment of a new steady state by treatment with agents that stimulate the physiologic adaptive mechanisms through the development of normally dormant defensive tissue reactions. Both in homeostasis and in heterostasis, the *milieu intérieur* participates actively.

We can stimulate the production of natural protective agents by treatment with chemicals that augment the induction of catatoxic or syntoxic enzymes, or by immunization with bacterial products (for example, vaccination) that increase the body's manufacture of serologic antibodies to combat infections.

In homeostatic defense the potential pathogen (which threatens the fixity of the *milieu intérieur*) automatically activates usually adequate catatoxic or syntoxic mechanisms; when these do not suffice, such natural catatoxic or syntoxic agents can also be administered readymade by the physician. Heterostasis depends upon treatment with artificial remedies that have no direct curative action, but which can precipitate the production of unusually high amounts of the body's own natural catatoxic or syntoxic agents so as to achieve fixity of the *milieu intérieur*, despite abnormally high demands that could not be met without outside help.

The most salient difference between homeostasis and heterostasis is that the former maintains a normal steady state by physiologic means, whereas the latter “resets the thermostat” of resistance to a heightened defensive capacity by artificial interventions from the outside (Figure 3). By chemical treatment, this process induces the body to raise the production of its own natural nonspecific (multipurpose) remedies. However, each type of planned or enforced training of the body through outside interventions also raises resistance from the homeostatic to the heterostatic level.

Heterostasis differs essentially from treatment with drugs (for example, antibiotics,

antacids, antidotes, pain killers) that act directly and specifically rather than by strengthening the body's own natural nonspecific defenses; in treatment with drugs, the *milieu intérieur* is passive.

Behavioral Implications

From what the laboratory and the clinical study of somatic diseases has taught me concerning stress, I have tried to arrive at a code of ethics based not on traditions of our society, inspiration, or blind faith in the infallibility of a particular prophet, religious leader or political doctrine, but on the scientifically verifiable laws that govern the body's reactions in maintaining homeostasis and living in satisfying equilibrium with its surroundings.

In a recent monograph (*Stress Without Distress*) on the behavioral implications of the stress concept, I attempted to show in more detail how we can adjust our personal reactions to enjoy fully the eustress of success and accomplishment without suffering the distress commonly generated by frustrating friction and purposeless aggressive behavior against our surroundings.

There I tried to illustrate this possibility by an example taken from daily life that shows how diseases can be produced indirectly by inappropriate or excessive adaptive reactions. When you meet a helpless drunk who showers you with insults but is obviously quite unable to do you any harm, nothing will happen if you take a syntoxic attitude—go past and ignore him. However, if you respond catatoxically and fight, or even only prepare to fight, the consequences may be tragic. You will discharge catecholamines that increase blood pressure and pulse rate, while your whole nervous system becomes alarmed and tense in anticipation of combat. If you happen to be a coronary candidate, the result may be a fatal brain hemorrhage or coronary accident. In this case, who is the murderer? The drunk didn't even touch you. This is biologic suicide! Death was caused by choosing the wrong reaction. If, on the other hand, the man who showers you with insults is a homicidal maniac with a dagger in his hand, evidently determined to kill you, you must take an aggressive catatoxic attitude. You must try to disarm him, even at the calculated risk of injury to yourself from the physical accompaniments of the alarm reaction in preparation for a fight. Contrary to common opinion, it is clear that Nature does not always know best, because on both the cellular and the interpersonal level, we do not always recognize what is and what is not worth fighting for.

Yet, it is a biologic law that man—like the lower animals—must fight and work for some goal that he considers worthwhile. We must use our innate capacities to enjoy the eustress of fulfillment. Only through effort, often aggressive egoistic effort, can we maintain our fitness and assure our homeostatic equilibrium with the surrounding society and the inanimate world. To achieve this state, our activities must earn lasting results; the fruits of work must be cumulative and must provide a capital gain to meet future needs. To succeed, we have to accept the scientifically established fact that man has an inescapable natural urge to work egoistically for things that can be stored to strengthen his homeostasis in the unpredictable situations with which life may confront him. These are not instincts we should combat or be ashamed of. We can do nothing about having been built to work, and it is primarily for our own good. Organs that are not used (muscles, bones, even the brain) undergo inactivity

atrophy, and every living being looks out first of all for itself. There is no example in Nature of a creature guided exclusively by altruism and the desire to protect others. In fact, a code of universal altruism would be highly immoral, since it would expect others to look out for us more than for themselves.

"Love thy neighbor as thyself" is a command filled with wisdom, but as originally expressed it is incompatible with biologic laws; no one needs to develop an inferiority complex if he cannot love all his fellow men on command. Neither should we feel guilty because we work for treasures that can be stored to ensure our future homeostasis. Hoarding is a vitally important biologic instinct that we share with animals such as ants, bees, squirrels and beavers.

How can we develop a code of ethics that accepts egoism and working to hoard personal capital as morally correct? That is what I attempted to do in *Stress Without Distress* and here I shall summarize the main conclusions in the form of three basic guidelines:

(1) *Find your own natural stress level.* People differ with regard to the amount and kind of work they consider worth doing to meet the exigencies of daily life and to assure their future security and happiness. In this respect, all of us are influenced by hereditary predispositions and the expectations of our society. Only through planned self-analysis can we establish what we really want; too many people suffer all their lives because they are too conservative to risk a radical change and break with traditions.

(2) *Altruistic egoism.* The selfish hoarding of the goodwill, respect, esteem, support and love of our neighbor is the most efficient way to give vent to our pent-up energy and create enjoyable, beautiful or useful things.

(3) *EARN thy neighbor's love.* This motto, unlike love on command, is compatible with man's structure, and although it is based on altruistic egoism, it could hardly be attacked as unethical. Who would blame him who wants to assure his own homeostasis and happiness by accumulating the treasure of other people's benevolence towards him? Yet this makes him virtually unassailable, for nobody wants to attack and destroy those upon whom he depends.

These are the three main principles derived from observations on the basic mechanisms that maintain homeostasis in cells, people and entire societies, and which help them face the stressors encountered in their constant fight for survival, security and well-being. Once understood and clearly formulated we can use them best by conscious control.

However, there remain many techniques whose value in improving the quality of life has been established by purely empirical observations. Although they are not directly related to attaining any particular goal, these techniques help us indirectly by improving our physical and mental fitness. Among these, I should mention muscular exercise, hot baths, saunas and a number of psychologic techniques such as Transcendental Meditation, yoga and Zen, whose beneficial effects upon general well-being and mental performance cannot yet be fully explained in somatic terms. With time, such explanation will undoubtedly become possible. Great progress has been made in this direction by demonstrations, for example, of the biochemical changes that accompany the refreshing relaxation induced by such different indirect means of improving well-being as athletics, relaxed meditation, a cup of coffee, or even psychotropic drugs (for example, tranquilizers). Of course, excessive or inappropriate use of any among these can cause considerable damage, and until we know more about their mechanisms

34 HISTORY AND GENERAL OUTLINE

of action, indications and contraindications cannot be clearly formulated for each individual in every situation. Yet in view of the great progress being made in our knowledge of the roles played by chemical compounds (catecholamines, 5-HT, hypothalamic neurohumors), it is in this field that we can see the greatest future for the further development of a code of behavior based upon biologic laws.

II. STRESSORS AND CONDITIONING AGENTS

The preceding chapter gave us an overview of the entire stress concept as we see it today, discussing its historical development, general outlines and special terminology. Now we shall have to turn our attention to a detailed résumé of the highlights of each point, namely:

1. the *stressors and conditioning agents*;
2. the *characteristic manifestations* of stress, including those that have diagnostic value;
3. the *diseases of adaptation*;
4. the *prophylaxis and treatment* of stress in general. (The management of diseases of adaptation will be discussed separately with each of these);
5. *theories* on the mechanism and general interpretation of stress reactions; and
6. *various other pertinent facts*, such as the legal and philosophic implications of the stress concept, as well as the societies, journals and institutes that deal with this subject.

In accordance with the principles of the analytico-synthetic style, in each instance we have started with a perusal of the entire pertinent literature, carefully collected by our library since the description of the stress syndrome in 1936. We have also included data published prior to 1936 that illustrate special aspects of the stress response, even though they were described before such implications could have been realized.

This analysis necessarily had to precede any attempt at a synthetic interpretation of the findings, and so in this volume we shall always begin with an analytic evaluation of the annotated references selected to illustrate each point. This résumé is meant only to act as a guide, assisting the reader in the selection of the individual papers he wishes to study in detail; it cannot pretend to offer a carefully reasoned evaluation of each point raised in the publications cited.

Trauma

Here, as in all subsequent sections of this guide to the stress literature, rapid orientation will be facilitated if we subdivide those topics about which an unusually large amount of data has been accumulated. This can be done according to various principles. For example, in the case of stressors, the material might be subdivided into separate observations on different species, age groups, the manifestations elicited in various targets, concurrent treatment with other stressors acting as conditioning agents, or even

just the chronologic order in which the observations were published. In this volume no uniform, rigid system has been adopted; instead, after the entire range of material available in each case had been studied, the subcategories were selected according to whatever system of classification appeared to be most convenient for the material at hand. Thus, in the present section, the subtitles refer to the most important target (which may be a chemical compound, or a morphologic or functional change); the section on Drugs classifies them alphabetically, while a later passage on Physical Agents used to elicit stress categorizes them according to their particular nature (for example, temperature variations, sound, rays, vibrations, electrical stimuli), and data on simple stressors, such as hemorrhage, are merely listed in chronologic order.

In most cases, the system of subdivision will be immediately obvious to the reader; any questions which might arise will be clarified by brief introductory explanations.

If the same publication deals with several especially important topics which must be considered in order to evaluate diverse aspects of stress, the publication will be included under each subdivision to which it is pertinent. To keep the synopsis of the stress literature as concise as possible, such duplications will be held to a minimum through the use of cross references in the event of heavily overlapping and inseparable subjects. For example, changes produced by stress in the ovaries should be considered under Sex as a conditioning factor which can influence stress susceptibility, and again under Sex in the section, Morphologic Changes. In all such instances, cross references will suffice to remind the reader of the additional sections under which he should search for relevant data.

However, those who really wish to gain access to as many data pertinent to their subject as possible are also advised to consult related sections using their own judgment, since even cross referencing has its practical limitations. For example, eosinopenia is listed as a morphologic characteristic of stress in general and also as a subdivision in almost all sections devoted to individual stressors, where this change has received special attention. It may be incidentally mentioned again in publications on any stressor, and of course, this cannot be indicated in every case by mere cross references. To illustrate, in the present section on Trauma, the subdivisions are arranged according to the stress manifestations that have received primary attention; eosinopenia may have been mentioned incidentally in almost any of these, and additional data will be found under the effect of trauma upon various Other Targets.

Finally, at the end of each section, we list data on the agent under study, when it is given in combination with some other agent which may modify its effect. However, relevant data will also be found under Multiple Stressors, when they illustrate cross-resistance or cross-sensitization in particular. Conversely, very general descriptions as well as reviews on the entire field are always listed under the name of the agent, characteristics, treatment, or theory under consideration.

Thus, in the present section, the subdivisions will be:

Generalities

ACTH and Corticoids

Catecholamines (EP, NEP)

STH

Insulin

Sex Hormones

Other Hormones

Histamine and 5-HT

Enzymes and Other Metabolites

Other Targets

Trauma + Other Agents

Generalities. Traumatic injury is one of the most commonly studied and most characteristic stressors, both in clinical and experimental medicine. Hence, the literature on its manifestations and prophylaxis has reached enormous proportions; nevertheless, the references given below will suffice for general orientation in this field. Acute and severe trauma causes typical alarm reaction changes in all species examined. In man, it is especially common, being an unavoidable consequence of surgery, in which case its manifestations are usually complicated by preoperative medication, anesthesia, anxiety, and loss of blood, making it quite impossible to determine the extent to which these associated factors have contributed to the production of any particular manifestation of surgical stress. (Hence, see also sections devoted to each of these agents.)

→**ACTH and Corticoids.** A rise in plasma ACTH and glucocorticoid levels is a very constant characteristic of stress; that it occurs regularly after traumatic injury has been well substantiated. ACTH is usually determined by bioassay on hypophysectomized rats, whereas corticoid levels are more accurately quantified by chemical methods. Data on 17-KS concentrations are difficult to interpret since these can be metabolites of either testosterone or corticoid hormones, whereas the levels of 11- or 17-hydroxycorticosteroids (11- or 17-OHCS), while not absolute, are more specific indicators of glucocorticoids in blood and urine.*

Since only the free steroids appear to be immediately effective in exerting their various biologic actions, a clear distinction should be made between these and their conjugates (for example, glucuronides or the transcortin-bound fraction).

The blood clearance of intravenously injected cortisol is delayed during surgical stress in man; this is perhaps partly due to impaired hepatic removal. Hence, a rise in blood corticoid levels cannot be ascribed solely to increased production.

In rats, traumatic stress (splenectomy) elicits an initial fall in the ACTH content of the pituitary within four hours, but after several days it reaches a peak of close to twice the normal level. Apparently, both the release and synthesis of ACTH are accelerated by surgical stress, the discharge being more rapid than resynthesis.

After gastrectomy, serum-free 17-OHCS levels in man rise more quickly than conjugated 17-OHCS, although the difference is not very impressive.

In adrenalectomized dogs given a constant intravenous infusion of cortisol, laparotomy induces a rise in free 17-OHCS, but this is not correlated with a fall in the plasma level of conjugated 17-OHCS, which either remains the same or is also increased. Presumably, the serum level of glucuronides is determined by multiple factors and is not an accurate index of their production or metabolism during surgery. In fact, there is good evidence that surgical interventions alter not only the absolute amount of corticoids excreted but also the rates of conjugation of free cortisol and cortisone.

Anesthesia and surgery decrease the binding of cortisol to albumin while the transcortin-binding capacity is unchanged.

→**Catecholamines (EP, NEP).** After surgical interventions in man, NEP is more constantly and significantly excreted in urine than is EP. However, the urinary excretion of both catecholamines rises significantly after serious surgical complications.

* At present, radioimmunologic techniques are being perfected.

→**STH.** In recent years, a good deal of evidence has been accumulated to support the view that plasma STH levels rise in the immediate postoperative period, reaching a peak after a few hours, as judged by radioimmunoassays. However, the response is often biphasic. Mere venipuncture can raise the blood STH level, especially in children. It has been postulated that STH may help to increase nonspecific resistance by providing a readily available source of energy in the form of FFA. Morphine anesthesia blocks not only cortisol but also STH production during surgical stress in man.

→**Insulin.** Several observations confirm that, in fasting men, plasma immunoreactive insulin concentrations are raised after surgical interventions simultaneously with the elevation of STH and cortisol. On the other hand, in rats the rise in plasma insulin caused by intravenous glucose is allegedly inhibited by trauma.

→**Sex hormones.** In general, traumatic as well as other stressors elicit a diminution of gonadotropic and gonadal hormones in both sexes, especially if exposure to the stressor is chronic. This is presumably a cause of the loss of libido and fertility in both sexes.

→**Other Hormones.** Plasma *vasopressin* levels rise in man following cardiac surgery and various cranial injuries. There is also some evidence that *thyroxine* metabolism and binding may be affected by trauma in the rat, and that, in patients after traumatic shocks, plasma *glucagon* and glucose levels rise considerably, often without any proportional increase in plasma *insulin*.

→**Histamine and 5-HT.** In mice, tourniquet shock allegedly activates 5-HT synthesis, which may interfere with the maintenance of circulatory homeostasis. In rats, some stressors deplete cerebral 5-HT and NEP, but this effect is produced neither by surgical shock nor by several other stressors, and is independent of the hypophysis.

→**Enzymes and Other Metabolites.** As compared with the many data on changes in cholesterol, glucose and enzyme mechanisms under the influence of various stressors, relatively little is known with regard to similar alterations during traumatic shock. Plasma renin activity in patients undergoing abdominal surgery is increased, but it remains to be shown that this is not a specific effect of interventions in the kidney region rather than a manifestation of stress.

→**Other Targets.** The other lesions ascribed to stress resulting from traumatic injuries are: eosinopenia, thrombocyte aggregation, and disseminated intravascular thromboembolism, as well as acceleration of fibrinolysis, circulatory disturbances, peptic ulcers, depression of RES activity, and psychologic changes related to the necessity of coping mentally with this form of stress.

+**Other Agents.** Age does not appear to play an important role in conditioning the hormonal response to traumatic injury. Adrenal ascorbic acid depletion following laparotomy in newborn rats is similar to that in adults, and children respond to cardiac catheterization with essentially the same corticoid excretion as adults.

Various *anesthetics* produce different intensities of 17-OHCS discharge in man but

subsequent surgery always causes a further rise. In rats, pentobarbital does not prevent tourniquet shock-induced ACTH discharge.

Mice survive tourniquet trauma better when kept at high rather than low *temperatures*.

Even *seasonal variations* in trauma sensitivity have been described, rats being more susceptible to trauma in November than in June or July.

Despite considerable work on the optimal *diet* needed to heighten resistance to trauma, all we can definitely say is that both excess and deficiency in food intake are detrimental.

Genetic factors also affect resistance to traumatic shock, but as yet, this subject has hardly been explored.

Trauma

(See also our earlier stress monographs, p. xiii)

Generalities. Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* **17**: 234-248 (1936). A56,032/36

First detailed description of the "alarm reaction" characterized by adrenocortical enlargement with acute loss of lipids, thymic colymphatic atrophy and decreased body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for forty-eight hours or more, large doses of atropine, morphine, formaldehyde or EP).

Noble, R. L., Collip, J. B.: "A quantitative method for the production of experimental traumatic shock without haemorrhage in unanaesthetized animals." *Q. J. Exp. Physiol.* **31**: 187-199 (1942). A56,106/42

Detailed description of the "Noble-Collip drum," which permits the production of graded degrees of shock in guinea pigs and rats by forcing them to run to avoid tumbling against projections and traumatizing themselves. This leads to typical thymus atrophy, adrenal hypertrophy, and other manifestations of the alarm reaction.

Hayes, M. A.: "Shock and the adrenocortex." *Surgery* **35**: 174-190 (1954). B93,820/54

Surgery produces various patterns of adrenocortical response depending "on the severity of the incurred stress and the availability of endogenous adrenocortical hormone to effect the necessary homeostatic readjustments."

→ **ACTH and Corticoids.** Forbes, A. P., Donaldson, E. C., Reifenstein, E. C. Jr., Al-

bright, F.: "The effect of trauma and disease on the urinary 17-ketosteroid excretion in man." *J. Clin. Endocrinol.* **7**: 264-288 (1947).

98,825/47

In normal individuals, 17-KS excretion usually rises for one to three days following injury and then almost always falls until convalescence. "In those debilitated patients where an alarm is not followed by a rise in 17-ketosteroids it is probable that, due to a previous alarm, they are already in the stage of resistance or even approaching the stage of exhaustion.... In chronically ill or debilitated individuals on the other hand, the initial level is subnormal and the response to injury usually small or absent. It is believed that these findings are further evidence that alterations in adrenal cortical function are an integral part of the adaptation syndrome of Selye and a link in our understanding of the part this syndrome plays in clinical medicine."

Franksson, C., Gemzell, C. A.: "Blood levels of 17-hydroxycorticosteroids in surgery and allied conditions." *Acta Chir. Scand.* **106**: 24-30 (1954).

E93,931/54

After surgical interventions and other traumatic procedures, plasma 17-OHCS greatly increase in man, reaching a peak on the first postoperative day and returning to normal within one to two weeks. Eosinopenia, 17-KS excretion, and erythrocyte sedimentation rates are less consistently altered by these stressors.

Moncrief, J. A., Weichselbaum, T. E., Elman, R.: "Changes in adrenocortical steroid concentration of peripheral plasma following surgery." *Surg. Forum* **4**: 469-473 (1954).

J11,248/54

Comparison of 17-OHCS levels in the plasma of chronically ill patients during fasting and in those with malignancies revealed higher levels in the latter group. After major operations, blood 17-OHCS levels rose in both groups, falling to normal within twenty-four hours.

Hume, D. M., Nelson, D. H.: "Adrenal cortical function in surgical shock." *Surg. Forum* **5**: 568-575 (1954).

E40,942/54

In the dog, surgical trauma markedly increases the 17-OHCS content of adrenal venous blood over that of convalescent animals, in which ACTH secretion drops considerably and shows intermittent variations. The cortex maintains high corticoid levels in severe shock despite substantially reduced blood

flow. However, when blood pressure drops to less than 35 mm. Hg, adrenal blood flow becomes so low that corticoid output is significantly diminished unless blood transfusions overcome the hypotension. Hemorrhage can increase corticoid output even above the level seen in surgical shock.

Sandberg, A. A., Eik-Nes, K., Samuels, L. T., Tyler, F. H.: "The effects of surgery on the blood levels and metabolism of 17-hydroxycorticosteroids in man." *J. Clin. Invest.* **33**: 1509-1516 (1954). B99,413/54

Surgical interventions cause a rapid increase in plasma 17-OHCS within the first hour. Intravenous cortisol is not cleared from the blood as rapidly during surgical stress as otherwise. Presumably, not only increased corticoid secretion but also decreased clearance contribute to the raised blood corticoid levels.

Franksson, C., Gemzell, C. A., Euler, U. S. von.: "Cortical and medullary adrenal activity in surgical and allied conditions." *J. Clin. Endocrinol. Metab.* **14**: 608-621 (1954).

B94,357/54

Immediately following surgery, all twenty-seven patients examined showed elevated 17-OHCS blood levels. The values were highest with shock or other complications. Urinary EP levels remained approximately within normal limits, but NEP values were occasionally high during the first seven days. The urinary concentration of both catecholamines were more often increased in patients with post-operative complications. "Determination of both the 17-OH blood level and catecholamine excretion may give valuable information as to the physiologic state of the patient."

Tyler, F. H., Schmidt, C. D., Eik-Nes, K., Brown, H., Samuels, L. T.: "The role of the liver and the adrenal in producing elevated plasma 17-hydroxycorticosteroid levels in surgery." *J. Clin. Invest.* **33**: 1516-1523 (1954). B99,414/54

Metabolic studies in man suggest that "the increased plasma levels of 17-hydroxycorticosteroid after surgery are the result of both increased adrenal secretion of these steroids and impaired hepatic removal."

Helmreich, M. L., Jenkins, D., Swan, H.: "The adrenal cortical response to surgery. II. Changes in plasma and urinary corticosteroid levels in man." *Surgery* **41**: 895-909 (1957) (25 refs.). C36,878/57

Hammond, W. G., Vandam, L. D., Davis, J. M., Carter, R. D., Ball, M. R., Moore, F. D.: "Studies in surgical endocrinology. IV. Anesthetic agents as stimuli to change in corticosteroids and metabolism." *Ann. Surg.* **148**: 199-211 (1958).

C57,405/58

"General anesthesia produced by Pentothal, nitrous oxide and d-tubo-curare in any combination was associated with significant changes in blood or urinary 17-hydroxycorticoid values. . . . Operation under Pentothal-N₂O-d-tubo-curare anesthesia was followed by an elevation of the free blood 17-OHCS, but the magnitude of the rise was not as great as that seen with operation under ether."

Fortier, C.: "Adenohypophyseal corticotrophin, plasma free corticosteroids and adrenal weight following surgical trauma in the rat." *Arch. Int. Physiol. Biochim.* **67**: 333-340 (1959).

C70,912/59

In rats, traumatic stress (splenectomy) caused a rapid fall in pituitary ACTH within four hours but after one to four days it rose to a peak of about twice the normal level. Plasma free corticoids rose to 600 percent of the baseline during the first hour and returned to normal within twenty-four hours. Adrenal weight increased to 120 percent of the controls within twelve hours and stabilized at this level until four days postoperatively, when it returned to normal values. It is suggested that "the rates of corticotrophin release and synthesis are accelerated, in successive and overlapping stages, by a mechanism triggered by stress, and depressed, in a similar fashion, by the elevation of the steroid level."

Steenburg, R. W., Smith, L. L., Moore, F. D.: "Conjugated 17-hydroxycorticosteroids in plasma: measurement and significance in relation to surgical trauma." *J. Clin. Endocrinol. Metab.* **21**: 39-52 (1961).

C98,414/61

In man, gastrectomy caused a rapid rise in the level of serum free 17-OHCS and a slower elevation of conjugated 17-OHCS, but

these differences were not statistically significant. In adrenalectomized dogs receiving constant intravenous infusion of cortisol, laparotomy elicited a rise in plasma free 17-OHCS, but this manifestation of a delay in steroid metabolism was not correlated with a fall in the plasma level of conjugated 17-OHCS, which remained the same or actually increased. "It is concluded that the serum concentration of glucuronide conjugates is determined by multiple factors, only one of which is the rate of their production. As such, their concentration in serum does not reflect the changes in the rate of steroid metabolism that often occur following surgical operations."

Cooper, C. E., Nelson, D. H.: "ACTH levels in plasma in preoperative and surgically stressed patients." *J. Clin. Invest.* **41**: 1599-1605 (1962) (33 refs.). D29,555/62

Espinier, E. A.: "Urinary cortisol excretion in stress situations and in patients with Cushing's syndrome." *J. Endocrinol.* **35**: 29-44 (1966). F66,914/66

Dörner, G., Stahl, F., Wendt, F., Schädlich, M.: "Beurteilung der Nebennierenrindenfunktion beim Operationsstress durch fluorimetrische Bestimmung von unkonjugiertem Kortisol und Kortikosteron im Plasma und Harn" (Evaluation of adrenal cortex function in surgical stress by fluorometric determination of unconjugated cortisol and corticosterone in plasma and urine). *Brunns Beitr. Klin. Chir.* **212**: 467-480 (1966).

G45,937/66

By use of an improved method for the fluorometric determination of unconjugated cortisol and corticosterone (11-OHCS), a distinct rise in blood and urine was noted. "The method easily allows to estimate quantitatively stress reactions of the hypothalamic-anterior lobe pituitary-suprarenal cortical system."

Olthoff, D., Gawellek, F.: "Die Ausscheidung von Nebennierenhormonen nach akuten Erkrankungen, Verletzungen und Operationen" (The excretion of adrenal gland hormones after acute diseases, injuries and surgery). *Zentralbl. Chir.* **92**: 1364-1367 (1967). F91,166/67

gery). *Zentralbl. Chir.* **92**: 1349-1355 (1967). F91,163/67

Review on the stressor effect of various operations with special emphasis upon urinary and blood corticoid levels.

Uozumi, T., Tanaka, H., Hamanaka, Y., Seki, T., Matsumoto, K., Akehi, A.: "Changes of urinary steroids following major surgical stress." *Endocrinol. Jap.* **14**: 7-10 (1967). F80,642/67

In patients who underwent pulmonary lobectomy, urinary excretion of 17-OHCS remained almost unchanged, but 17-KS clearance decreased gradually. Furthermore, "the ratios of etiocholanolone to androsterone and tetrahydrocortisone + tetrahydrocortisol + cortisol to allotetrahydrocortisol increased significantly following operation, even 6 to 8 months after surgical stress. It is suggested that these findings of urinary steroids following operation may reflect some of the non-specific metabolic responses to a major surgical stress."

Asfeldt, V. H., Elb, S.: "Hypothalamo-pituitary-adrenal response during major surgical stress." *Acta Endocrinol. (Kh.)* **59**: 67-75 (1968). H2,076/68

As indicated by the fall in plasma corticosteroids during surgical interventions in man, "suppression by dexamethasone has no influence on the hypothalamic pituitary adrenal response to major acute stress."

Gottfried, I., Lewenthal, H., Goldberg, S.: "Free 11-hydroxycorticosteroids in plasma and urine in pregnancy and in cases of stress." *Am. J. Obstet. Gynecol.* **102**: 924-927 (1968). G62,921/68

The free plasma and urinary 11-OHCS levels were measured in normal nonpregnant and normal pregnant women, those with a suspected fetal death, and in female patients after surgical stress.

Fossati, P.: "Manifestations endocrino-métaboliques de l'aggression cérébrale" (Endocrine-metabolic reactions to cranial injury). *Acta Anaesthesiol. Belg.* **19**: 284-307 (1968). G70,695/68

Cranial injuries produce general reactions to stress as well as other specific effects. The plasma cortisol level increases, as does the urinary output of 17-KS and 17-OHCS. "Production of ADH is also increased. A diencephalo-pituitary deficiency may be caused by the rupture of the pituitary stem or by ischaemic necrosis of the hypophysis" (49 refs.).

Plumpton, F. S., Besser, G. M.: "The adrenocortical response to surgery and insulin-induced hypoglycaemia in corticosteroid-treated and normal subjects." *Br. J. Surg.* **56**: 216-219 (1969). H9,868/69

In patients undergoing major surgery or experiencing insulin hypoglycemia, concurrent prednisolone administration usually (though not always) failed to produce the increase in plasma corticoids normally elicited by these stressors, but only for a limited length of time.

Sólyom, J., Sturcz, J., Spát, A., Mészáros, I., Ludwig, E.: "In vitro steroid production by the adrenal gland of intact rats and rats subjected to surgical stress." *Acta Physiol. Acad. Sci. Hung.* **36**: 371-377 (1969).

J20,199/72

Kudo, S., Terayama, Y., Tamura, M., et al.: "Fluctuation of urinary 17-OHCS fractions in before and after surgical stress." *Clin. Endocrinol. (Tokyo)* **20**: 149-156 (1972) (Japanese).

J20,752/72

Kawamura, J.: "Clinical studies on the changes of blood and urinary glucocorticoid in renal failure. I. The change of blood glucocorticoid in acute renal failure with special regard to the plasma cortisol level and blood cell sodium and potassium under stress condition." *Acta Urol. (Kyoto)* **18**: 185-221 (1972) (Japanese). H81,033/72

In patients with acute renal failure treated by hemodialysis or peritoneal lavage, plasma cortisol levels rose, perhaps owing to a decrease in urinary 17-OHCS excretion. "Besides, in acute renal failure, stress such as surgery or trauma might have stimulated the hypothalamo-pituitary-adrenocortical system promoting cortisol excretion from the adrenal" (168 refs.).

Khomitskaya, L. F.: "Glucocorticoid function of the adrenals during surgery involving excision of the tumors of cerebral hemi-

spheres." *Vop. Neirokhir.* **36** No. 5: 27-32 (1972) (Russian). H81,437/72

After surgical interventions, urinary 17-OHCS excretion rose in sixty-two patients. Previous responses to ACTH did not correctly foretell the intensity of such stress reactions.

Spät, A., Józan, S.: "Displacement analysis of aldosterone and corticosterone in the rat adrenal venous blood." *J. Steroid Biochem.* **4**: 509-518 (1973). J9,302/73

Simultaneous determination of aldosterone and corticosterone levels in the adrenal venous blood of rats using a new technique. Even the mild stress of changing the environment caused consistent increases in corticosterone but rises in aldosterone were only irregularly observed, even after severe surgical stress.

Fossati, P., Lefebvre, J., Cappoen, J. P., Racadot, A., Lesaffre, J., Laine, E., Linquette, M.: "La fonction gluco-corticoïde du traumatisé crânien" (Glucocorticoid function in patients with cranial injury). *Ann. Endocrinol.* (Paris) **34**: 145-157 (1973).

H71,925/73

In patients with cranial injury, the increased values of plasma cortisol, corticosterone and dialysable cortisol diminish progressively within a week, as they do following surgery (41 refs.).

Funyu, T., Kudoh, S., Shiraiwa, Y., Terayama, Y., Nigawara, K., Hitomi, H.: "Changes in fractions of urinary free 17-hydroxy-corticosteroids before and after operation." *Tohoku J. Exp. Med.* **111**: 61-69 (1973). H81,184/73

The stress of surgical operations alters not only the absolute amount of corticoids excreted, but also the rates of conjugation of free cortisol and cortisone.

Allen, J. P., Kendall, J. W., McGilvra, R., Lamorena, T. L., Castro, A.: "Adrenocorticotrophic and growth hormone secretion. Studies during pneumoencephalography." *Arch. Neurol.* **31**: 325-328 (1974).

J17,778/74

"Associated with the stress of the procedure, both ACTH and growth hormone concentrations increased in the plasma without a corresponding change in CSF levels of these two hormones."

Kehlet, H., Binder, C., Engbaek, C.: "Cortisol binding capacity in plasma during

anaesthesia and surgery." *Acta Endocrinol.* (Kh.) **75**: 119-124 (1974). H81,710/74

In man, anesthesia and surgery decrease the binding of cortisol to albumin while transcortin binding capacity remains unchanged.

Hollmann, G., Fischer, A., Körner, J.: "Besonderheiten der Pathophysiologie des Operationstraumas im Kindesalter" (Peculiarities of the pathophysiology of surgical trauma in children). *Münch. Med. Wochenschr.* **116**: 1213-1218 (1974). H88,808/74

In children undergoing major operations the sympathetic adrenergic response is more manifest than in adults, and while the plasma cortisol levels often show little or no rise, indirect metabolic reactions suggest that excess aldosterone production occurs in response to a special need at an early age (20 refs.).

→**Catecholamines (EP, NEP).** Franksen, C., Gemzell, C. A., Euler, U. S. von.: "Cortical and medullary adrenal activity in surgical and allied conditions." *J. Clin. Endocrinol. Metab.* **14**: 608-621 (1954).

B94,357/54

Immediately following surgery, all twenty-seven patients examined showed elevated 17-OHCS blood levels. The values were highest in patients with shock or other complications. Urinary EP levels remained within approximately normal limits, but NEP values were occasionally high during the first seven days. The urinary concentration of both catecholamines increased more often in patients with postoperative complications. "Determination of both the 17-OH blood level and catecholamine excretion may give valuable information as to the physiologic state of the patient" (21 refs.).

Klensch, H.: "Der basale Noradrenalin-spiegel im peripheren venösen Blut des Menschen" (The basal noradrenaline content in the peripheral venous blood of man). *Pflügers Arch.* **290**: 218-224 (1966).

F69,584/66

Insertion of a cannula into the cubital vein raises blood pressure and pulse rate for only about ten minutes, whereas NEP levels remain elevated for about twenty minutes.

Carruthers, M., Taggart, P., Conway, N., Bates, D., Somerville, W.: "Validity of plasma-catecholamine estimations." *Lancet* July 11, 1970, pp. 62-67. H27,193/70

In man, venipuncture raises the blood catecholamine content. When several samples

are taken through an indwelling catheter, the results are not significantly altered although strong individual variations make interpretation difficult.

Klensch, H., Gött, U.: "Liquor-Adrenalin und -Noradrenalin im Operationsstress" (CSF-adrenaline and -noradrenaline in surgical stress). *Klin. Wochenschr.* **48**: 853-855 (1970). H27,637/70

In man, the stress of surgical operations causes a more pronounced rise in the NEP content of the CSF than in that of the plasma, whereas the EP level does not vary significantly.

Nikki, P., Takki, S., Tammisto, T., Jäätelä, A.: "Effect of operative stress on plasma catecholamine levels." *Ann. Clin. Res.* **4**: 146-151 (1972). G92,448/72

Rao, L. N., Bhatt, H. V.: "Stress response during surgery and anesthesia indicated by norepinephrine concentration in plasma of surgical patients." *Int. Surg.* **57**: 294-298 (1972). H54,659/72

Eisele, R., Lohmann, F. W., Kötter, D., Nasseri, M.: "Das Verhalten der Plasmakatecholamine nach Bauchoperationen beim Menschen" (Plasma catecholamine levels after abdominal operations in man). *Langenbecks Arch. Chir.* **336**: 103-113 (1974) (27 refs.). J17,952/74

J15,791/74

In chronic alcoholics tolerance to anesthetics is reflected in an increased sympathetic activity during operative stress.

Hashimoto, Y., Kurobe, Y., Hirota, K.: "Effect of delivery on serum dopamine- β -hydroxylase activity and urinary vanillyl mandelic acid excretion of normal pregnant subjects." *Biochem. Pharmacol.* **23**: 2185-2187 (1974). H89,340/74

"The emotional and physiological stress of delivery" produced an increase in serum dopamine- β -hydroxylase and VMA.

→**STH.** Ross, H., Johnston, I. D. A., Wellborn, T. A., Wright, A. D.: "Effect of abdominal operation on glucose tolerance and serum levels of insulin, growth hormone, and hydrocortisone." *Lancet* September 10, 1966, pp. 563-566. F69,882/66

In man, abdominal operations produce high fasting blood glucose levels and reduced tolerance to intravenous glucose. Fasting plasma insulin levels are raised postoperatively, and intravenous glucose produces greater elevations of serum insulin and STH in the immediate postoperative period.

Ketterer, H., Powell, D., Unger, R. H.: "Growth hormone response to surgical stress." *Clin. Res.* **14**: 65 (1966). F82,744/66

Radioimmunoassays show that human plasma STH levels rise within an hour after surgery, reach a peak after two to four hours, and may remain elevated for days postoperatively.

Krulich, L., McCann, S. M.: "Influence of stress on the growth hormone (GH) content of the pituitary of the rat." *Proc. Soc. Exp. Biol. Med.* **122**: 612-616 (1966).

F67,299/66

In rats, pituitary STH activity (epiphysial cartilage test) was initially decreased and then increased after splenectomy. Formalin injections and the ringing of a doorbell raised pituitary STH, cold (3°C) depleted it and fasting caused a biphasic reaction with an initial depletion and a return to normal followed by a secondary depletion after about three days. These and other data suggest that STH secretion in the rat "is very labile and influenced by a variety of stresses as well as by alterations in the supply of available carbohydrate."

Copinschi, G., Hartog, M., Earll, J. M., Havel, R. J.: "Effect of various blood sampling procedures on serum levels of immunoreactive human growth hormone." *Metabolism* **16**: 402-409 (1967). F83,864/67

Arterial catheterization caused a rise in serum immunoreactive STH. For unknown reasons, infusion of NEP and a cold-pressor test elicited no similar change although the literature shows many examples of such a rise in man and animals after exposure to various stressors (28 refs.).

Helge, H., Weber, B., Quabbe, H. J.: "Growth-hormone release and venipuncture." *Lancet* January 25, 1969, p. 204.

H7,240/69

After a brief review of the literature on stress-induced increases in plasma STH, the authors report personal observations showing that venipuncture produces this effect more commonly in children than in adults or in newborns. "These observations suggest that, for children more often than for newborns or

adults, a rather harmless medical procedure can represent an iatrogenic stress."

Newsome, H. H., Rose, J. C.: "The response of human adrenocorticotropic hormone and growth hormone to surgical stress." *J. Clin. Endocrinol. Metab.* **33**: 481-487 (1971). H45,875/71

Observations on patients who have undergone various forms of surgery suggest that STH and ACTH plasma levels rise in a parallel fashion and are presumably mediated through a common afferent pathway in the spinal cord.

Geser, C. A., Felber, J. P., Brand, E., Schultis, K.: "Untersuchungen zur Glucagon-induzierten Sekretion von Wachstumshormon und Insulin und deren Einfluss auf Parameter des Kohlenhydrat- und Fettstoffwechsels nach einem Operationsstress" (Studies on glucagon-induced secretion of growth hormone and insulin and its influence on the parameters of carbohydrate and lipid metabolism following surgical stress). *Klin. Wochenschr.* **49**: 1175-1182 (1971). H48,219/71

Carey, L. C., Cloutier, C. T., Lowery, B. D.: "Growth hormone and adrenal cortical response to shock and trauma in the human." *Ann. Surg.* **174**: 451-460 (1971).

G86,425/71

In U.S. Marines injured during battle plasma STH levels rose markedly and constantly, whereas cortisol concentrations remained normal or were only slightly elevated. It is possible that STH provides an additional energy source in the form of FFA. The literature on STH secretion during various other types of stress is briefly reviewed. In the discussion following this paper it is mentioned that cortisol excretion apparently is minimal in stress associated with severe shock. However, some investigators have found very high cortisol levels following fatal traumatic injury (26 refs.).

Salter, C. P., Fluck, D. C., Stimmmer, L.: "Effect of open-heart surgery on growth hormone levels in man." *Lancet* October 21, 1972, pp. 853-854. H59,995/72

Plasma STH levels rose dramatically during open-heart surgery and fell to virtually normal within seven days.

George, J. M., Reier, C. E., Lanese, R. R., Rower, J. M.: "Morphine anesthesia blocks cortisol and growth hormone response to sur-

gical stress in humans." *J. Clin. Endocrinol. Metab.* **38**: 736-741 (1974). H86,212/74

Singh, A. K., Chansouria, J. P. N., Singh, R. K., Wahi, R. S., Udupa, K. N.: "Hormonal and metabolic alterations following surgical trauma." *Fifth Asia & Oceania Congr. Endocr.*, pp. 50-51. Chandigarh, India, 1974. H82,068/74

In man, the stress of major surgery caused an increase in plasma STH, cortisol and FFA, and a decrease in plasma insulin.

Allen, J. P., Kendall, J. W., McGilvra, R., Lamorena, T. L., Castro, A.: "Adrenocorticotropic and growth hormone secretion. Studies during pneumoencephalography." *Arch. Neurol.* **31**: 325-328 (1974).

J17,778/74

"Associated with the stress of the procedure, both ACTH and growth hormone concentrations increased in the plasma without a corresponding change in CSF levels of these two hormones."

→**Insulin.** Ross, H., Johnston, I. D. A., Welborn, T. A., Wright, A. D.: "Effect of abdominal operation on glucose tolerance and serum levels of insulin, growth hormone, and hydrocortisone." *Lancet* September 10, 1966, pp. 563-566. F69,882/66

In man, abdominal operations are followed by high fasting blood glucose levels and reduced tolerance to intravenous glucose. Fasting plasma insulin levels are raised post-operatively, and intravenous glucose produces greater elevations of serum insulin and STH in the immediate postoperative period.

Geser, C. A., Felber, J. P., Brand, E., Schultis, K.: "Untersuchungen zur Glucagon-induzierten Sekretion von Wachstumshormon und Insulin und deren Einfluss auf Parameter des Kohlenhydrat- und Fettstoffwechsels nach einem Operationsstress" (Studies on glucagon-induced secretion of growth hormone and insulin and its influence on the parameters of carbohydrate and lipid metabolism following surgical stress). *Klin. Wochenschr.* **49**: 1175-1182 (1971). H48,219/71

Vigaš, M., Németh, S., Jurčovičová, J.: "Stress-induced inhibition of insulin release in non-conditioned and conditioned rats." In: Németh, S., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 143-150. Bratislava: Slovak Academy of Sciences, 1973. E10,464/73

Whereas normal rats responded to 1 gm. per kg. intravenous glucose by a prompt rise

in plasma immunoreactive insulin, this reaction was completely suppressed after traumatization in the Noble-Collip drum. The blockade was prevented by bilateral adrenalectomy or by repeating the injury daily for 7 days (13 refs.).

Koch, G.: "Vergleichende Untersuchungen über das Blutglukose- und Plasmainsulinverhalten am traumatisierten Kaninchen" (Blood glucose and plasma insulin levels of traumatized rabbits, an experimental study). *Bruns Beitr. Klin. Chir.* **221**: 158-163 (1974). J17,605/74

In rabbits, surgical trauma causes hyperglycemia and an increase in plasma insulin, both of which are ascribed to the G.A.S.

Singh, A. K., Chansouria, J. P. N., Singh, R. K., Wahi, R. S., Udupa, K. N.: "Hormonal and metabolic alterations following surgical trauma." *Fifth Asia & Oceania Congr. Endocr.*, pp. 50-51. Chandigarh, India, 1974. H82,068/74

In man, the stress of major surgery caused an increase in plasma STH, cortisol and FFA, and a decrease in plasma insulin.

Vigaš, M., Németh, S., Jurčovičová, J.: "Effect of trauma on insulin response to glucose in thyroidectomized rats." *Endocrinol. Exp.* **8**: 147-151 (1974). H88,658/74

The degree of posttraumatic decrease in insulin secretion following glucose administration is diminished by thyroidectomy.

→**Sex Hormones.** Eiff, A. W. von, Plötz, E. J., Beck, K. J., Czernik, A.: "The effect of estrogens and progestins on blood pressure regulation of normotensive women." *Am. J. Obstet. Gynecol.* **109**: 887-892 (1971). G81,851/71

Both folliculoids and luteoids enhance the rise in blood pressure, respiratory rate and muscle tone in ovariectomized women performing a simple arithmetic task with or without noise.

Monden, Y., Koshiyama, K., Tanaka, H., Mizutani, S., Aono, T., Hamanaka, Y., Uozumi, T., Matsumoto, K.: "Influence of major surgical stress on plasma testosterone, plasma LH and urinary steroids." *Acta Endocrinol. (Kbh.)* **69**: 542-552 (1972). H52,372/72

Aono, T., Kurachi, K., Mizutani, S., Hamanaka, Y., Uozumi, T.: "Influence of major surgical stress on plasma levels of testosterone, luteinizing hormone and follicle-

stimulating hormone in male patients." *J. Clin. Endocrinol. Metab.* **35**: 535-542 (1972). H59,966/72

→**Other Hormones.** Goldenberg, I. S., Hayes, M. A., Greene, N. M.: "Endocrine responses during operative procedures." *Ann. Surg.* **150**: 196-201 (1959). C72,662/59

In man, *thyroid* activation has been observed after surgery, as reflected by circulating PBI-131.

Gejrot, T., Notter, G.: "Effects of surgical stress on thyroid function in man." *Acta Otolaryngol. (Stockh.)* **55**: 2-10 (1962). D57,721/62

The uptake of radioiodide by the *thyroid* was decreased during the first forty-eight hours after surgery but increased thereafter.

Fossati, P.: "Manifestations endocrinométaboliques de l'agression cérébrale" (Endocrine-metabolic reactions to cranial injury). *Acta Anaesthesiol. Belg.* **19**: 284-307 (1968). G70,695/68

Cranial injuries produce general reactions to stress. Plasma cortisol increases and so does the urinary output of 17-KS and 17-OHCS. "Production of *ADH* is also increased. A diencephalo-pituitary deficiency may be caused by the rupture of the pituitary stem or by ischaemic necrosis of the hypophysis" (49 refs.).

Richards, J. R., Harland, W. A., Orr, J. S.: "Factors affecting thyroid hormone metabolism in experimental trauma." In: Németh, S., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 151-161. Bratislava: Slovak Academy of Sciences, 1973. E10,465/73

In rats, fractures of the femur cause a transient increase in *thyroxine* secretion without any change in serum thyroxine or protein-bound iodine. Others have shown that plasma levels of free thyroxine and triiodothyronine rise rapidly after injuries, whereas the thyroxine-binding capacity of prealbumin decreases. "These alterations in the peripheral metabolism and transport of thyroxine may well play an important role in the metabolic consequences of injury."

Soliman, M. G., Brindle, G. F.: "Plasma levels of anti-diuretic hormone during and after heart surgery with extra corporeal circulation." *Can. Anaesth. Soc. J.* **21**: 195-204 (1974). J10,760/74

Plasma vasopressin increased in seven patients during cardiac surgery with extracor-

poreal circulation. This was "probably due to changes in serum osmolalities, surgical trauma and the action of anaesthetic drugs." The literature on the effects of various stressors upon plasma vasopressin is discussed (25 refs.).

Lindsey, A., Santeusanio, F., Braaten, J., Falloona, G. R., Unger, R. H.: "Pancreatic alpha-cell function in trauma." *J.A.M.A.* **227**: 757-761 (1974). H82,359/74

Following traumatic shock, patients' plasma glucagon levels rose far above normal and blood glucose averaged 188 mg. per 100 ml. whereas insulin remained unchanged. "In three patients undergoing major surgery without associated hypotension, glucagon concentrations did not rise comparably. Hyperglucagonemia without a proportional rise in insulin may be the usual islet cell response to severe trauma and possibly could contribute to survival."

Meguid, M. M., Brennan, M. F., Aoki, T. T., Muller, W. A., Ball, M. R., Moore, F. D.: "Hormone-substrate interrelationships following trauma." *Arch. Surg.* **109**: 776-783 (1974). J19,976/74

Observations in man lead to the conclusion that "in trauma, the gradual rise in glucagon contributes to the increase in concentration of glucose and FFA, and that the cortisol rise synergizes with the elevated glucagon concentration to favor gluconeogenesis from muscle amino acids. Relatively low circulating insulin levels favor these metabolic changes" (62 refs.).

Russell, R. C. G., Walker, C. J., Bloom, S. R.: "Hyperglucagonaemia in the surgical patient." *Br. Med. J.* January 4, 1975, pp. 10-12. H97,996/75

→**Histamine and 5-HT.** Schayer, R. W.: "Role of induced histamine in tourniquet shock in mice." *Am. J. Physiol.* **203**: 412-416 (1962). D32,955/62

Observations on mice traumatized with a tourniquet "suggest that the fundamental process leading to shock after fluid loss is activation of histamine synthesis in or near cells of the capillaries to restore an adequate supply of blood to the tissues. Since induced histamine synthesis is controlled by local conditions, opening of the capillary beds proceeds independently of the over-all circulatory picture; finally, homeostasis can no longer be maintained."

Barchas, J. D., Freedman, D. X.: "Brain amines: response to physiological stress." *Biochem. Pharmacol.* **12**: 1232-1238 (1963). E29,915/63

In rats, swimming to exhaustion especially in cold water caused depletion of brain 5-HT and NEP. Similar changes could not be obtained by having the rats run in a revolving cage, for under the conditions of the experiment the rats soon gave up and just allowed themselves to be dragged. Immersion in cold water did reproduce the catecholamine depletion whereas several other stressors (electroshock, starvation, hypoxia, surgery, adrenalectomy) were ineffective in this respect. The response is not dependent upon the pituitary-adrenocortical system, since active stressors deplete brain catecholamines even after hypophysectomy, as does LSD. It is noteworthy that drugs which induce a similar change in brain amines produce a unique pattern of central excitation, acting on brain mechanisms concerned with metabolic and physiologic temperature regulation. "If the stressors have such a central action, a role for the biogenic amines in central as well as in peripheral aspects of temperature regulation should be sought."

→**Enzymes.** Németh, Š.: "Plasma glucocorticoid and liver enzyme responses in the stressed rat." In: Németh, Š., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 229-241. Bratislava: Slovak Academy of Sciences, 1973. E10,471/73

In rats subjected to stress in the Noble-Collip drum "no acute or long-term changes of glucose-6-phosphatase and phosphoenol-pyruvate carboxykinase were found after single or repeated injury. An increased activity of tyrosine aminotransferase was observed, 90 minutes as well as 3 hours after a first injury and evidence is presented indicating that the enzymic response is dependent on increased plasma corticosterone levels. The plasma corticosterone and transaminase responses of the repeatedly injured rats were of substantially shorter duration than those of rats injured for the first time."

Németh, Š., Vigaš, M., Straková, A.: "Effect of trauma and hydrocortisone on liver tyrosine-alpha-ketoglutarate transaminase activity of rats adapted to Noble-Collip drum trauma." *Physiol. Bohemoslov.* **22**: 355-358 (1973). J9,812/73

In rats adapted to trauma in a Noble-

Collip drum, the increase in hepatic tyrosine-alpha-ketoglutarate transaminase was not changed by subsequent minor traumas of the same kind although hypercorticosteronemia, which probably induces this enzyme activity, was substantially diminished by adaptation. Adrenalectomy prevented the enzyme response irrespective of adaptation.

Galvin, M. J. Jr., Bunce, R., Reichard, S. M.: "Histidine decarboxylase activity in traumatic shock." *Proc. Soc. Exp. Biol. Med.* **146**: 653-657 (1974). H89,001/74

In rats, trauma (Noble-Collip drum) increases histidine decarboxylase activity in the lung and spleen but not in plasma. Literature is cited to show that the RES "is altered by similar types of stress and by histamine."

Moore, T. C., Sinclair, M. C., McAlpin, C. D., Weber, G. A., Lemmi, C. A. E.: "Effect of aging, organ allografting, and surgical stress on rat thymus histidine decarboxylase activity." *Surgery* **76**: 733-740 (1974). J17,862/74

Oehler, G., Wolf, H., Schmahl, F. W., Roka, L.: "Veränderungen der Lipoproteinfatlipase nach experimenteller Femurfraktur" (Changes in lipoprotein-lipase after experimental fracture of the femur). *Z. Gesamte Exp. Med.* **163**: 31-38 (1974). H87,841/74

In rabbits, fracture of the femur caused a significant decrease in heparin-insoluble lipoprotein-lipase with a concurrent increase in serum glycerides and in the excretion of catecholamines during the first twenty-four hours. There was also histologic evidence of pulmonary fat embolism. It is concluded "in addition to the increased synthesis of triglycerides during the post-traumatic phase (lipid mobilization syndrome) the elimination of blood lipids is impaired by decreased LPL [lipoprotein-lipase] activity. The elevated release of catecholamine is probably of essential significance for both effects."

→**Other Metabolites.** Zarafonetis, C. J. D., Seifter, J., Baeder, D., Kalas, J. P.: "Lipid mobilization as a consequence of surgical stress." *Am. J. Med. Sci.* **237**: 418-433 (1959). C67,041/59

Goodman, J. R., Kellogg, F., Porter, R. W., Liechti, R.: "Decrease in serum cholesterol with surgical stress." *Calif. Med.* **97**: 278-280 (1962). D55,584/62

Serum cholesterol decreased in patients as

a result of surgery. "A presurgical drop was noted and considered to be related to psychological stress."

Ross, H., Johnston, I. D. A., Welborn, T. A., Wright, A. D.: "Effect of abdominal operation on glucose tolerance and serum levels of insulin, growth hormone, and hydrocortisone." *Lancet* September 10, 1966, pp. 563-566. F69,882/66

Abdominal operations are followed by high fasting blood glucose levels and reduced tolerance to intravenous glucose. Fasting plasma insulin levels are raised postoperatively, and intravenous glucose produces greater elevations of serum insulin and STH in the immediate postoperative period.

Szantay, I., Acalovschi, I.: "Aspects du métabolisme de la ³⁵S-méthionine au cours du stress opératoire" (Aspects of ³⁵S-methionine metabolism during surgical stress). *Agressologie* **11**: 389-394 (1970). H32,849/70

Studies with ³⁵S-methionine revealed an increased metabolism in patients, following various operations.

Stremmel, W.: "Die Bedeutung des Blutglykogens nach stressinduzierten Stoffwechselstörungen" (The importance of blood glycogen concentration after stress-induced metabolic disturbances). *Brunn's Beitr. Klin. Chir.* **220**: 297-305 (1973). J3,874/73

In man, the stress of surgical interventions raises blood glycogen. A similar change is seen after exposure to various stressors and may be responsible for increased platelet adhesiveness and stress-induced thrombosis.

Turton, M. B., Deegan, T.: "Central and peripheral levels of plasma catecholamines, cortisol, insulin and non-esterified fatty acids." *Clin. Chim. Acta* **48**: 347-352 (1973). J8,031/73

In patients undergoing cardiac catheterization, elevated levels of EP, NEP, FFA and cortisol with lowered concentrations of insulin are ascribed to stress. However, certain differences are noted in the concentrations of these substances in various vascular territories.

Koch, G.: "Vergleichende Untersuchungen über das Blutglukose- und Plasmainsulinverhalten am traumatisierten Kaninchen" (Blood glucose and plasma insulin levels of traumatized rabbits, an experimental study). *Brunn's Beitr. Klin. Chir.* **221**: 158-163 (1974). J17,605/74

In rabbits, surgical trauma causes *hyperglycemia* and an increase in plasma insulin, both of which are ascribed to the G.A.S.

→**Other Targets.** Laragh, J. H., Almy, T. P.: "Changes in circulating eosinophils in man following epinephrine, insulin, and surgical operations." *Proc. Soc. Exp. Biol. Med.* **69**: 499-501 (1948).

B31,814/48

In man, surgical trauma and injections of EP or insulin caused *eosinopenia*.

Gabrilove, J. L.: "The level of the circulating eosinophils following trauma." *J. Clin. Endocrinol.* **10**: 637-640 (1950).

B48,579/50

In man, the stress of surgical trauma or of coronary occlusion causes *eosinopenia* followed by a rise in blood eosinophils above the normal level, the curve running approximately parallel to corticoid secretion and resembling that elicited by ACTH or glucocorticoids.

Hamburg, D. A.: "Psychological adaptive processes in life-threatening injuries." In: *Symposium on Stress*, pp. 222-235. Washington, D.C.: Army Medical Service Graduate School, 1953.

B89,532/53

Detailed discussion of the various *mental defense* reactions with which people having different psychologic characteristics meet the challenge of life-threatening situations, particularly severe injuries and imminent stress. Among these responses, there are three general types: "those which tend to make the patient feel that his life is not really in danger; those which tend to make him feel unafraid of impending death; and those which tend to make him feel that he will recover. All of these emergency defenses are usually facilitated by the diffuse impairment of brain function often associated with severe injury. This impairment makes it easier for the patient to restrict his awareness, to perceive only what he wants to perceive, and to delay recognition of the threat to life."

Engquist, A., Winther, O.: "Variations of plasma cortisol and blood fibrinolytic activity during anaesthetic and surgical stress." *Br. J. Anaesth.* **44**: 1291-1297 (1972).

J672/72

In man, during thirty to ninety-three minutes of "surgical stress, enhancement of *fibrinolysis* was significantly correlated with increase of plasma cortisol levels."

Cohen, F., Lazarus, R. S.: "Active coping processes, coping disposition, and recovery

from surgery." *Psychosom. Med.* **35**: 375-389 (1973).

J7,262/73

Mainly *psychologic* studies on coping processes in preoperative and postoperative patients, with statistical data on the effect of avoidant and vigilant behavior upon recovery (37 refs.).

Scovill, W. A., Saba, T. M.: "Humoral recognition deficiency in the etiology of reticuloendothelial depression induced by surgery." *Ann. Surg.* **178**: 59-64 (1973).

J4,221/73

The phagocytic activity of the *RES* is greatly depressed in dogs during and after major abdominal surgery. This depression can be prevented by passive opsonin administration. "The potential depletion of opsonic protein by the entrance of damaged tissue or denatured protein in the circulation or the consumption of opsonin at the site of tissue injury may trigger this state of 'hypo-opsonemia.' In addition, preliminary findings suggest a role for the pituitary-adrenal axis in this response."

Stremmel, W.: "Stressinduzierte Stoffwechselveränderungen und gesteigerte Thrombozyten-Aggregation nach Operationen und Traumen" (Stress-induced metabolic changes and enhanced thrombocyte aggregation after surgery and trauma). *Münch. Med. Wochenschr.* **115**: 416-421 (1973).

H68,723/73

In man, various operations and other traumatic injuries enhance thrombocyte aggregation and may cause postoperative thromboembolism or disseminated *intravascular coagulation*. The stress-induced increase in FFA may play a role in this response (40 refs.).

Mazurkevich, G. S.: "Distribution of fractions of circulating and deposited blood in the hypothalamus, hypophysis, and the adrenal glands, and their oxygen regimen in traumatic shock." *Probl. Endokrinol.* **20** No. 1: 59-62 (1974) (Russian).

H85,172/74

In rats subjected to severe traumatic shock "under conditions of pronounced hypotension and hypovolemia, the capacity of the functioning *vascular* bed and the oxygen tension in the adrenal glands decreased more than in the adenohypophysis and the area of the median eminence. Circulatory disturbances and hypoxia of the adrenal cortex could serve as one of the causes of depressed production of corticosteroids during this process."

Galvin, M. J. Jr., Bunce, R., Reichard, S. M.: "Histidine decarboxylase activity in traumatic shock." *Proc. Soc. Exp. Biol. Med.* **146**: 653-657 (1974). H89,001/74

In rats, trauma (Noble-Collip drum) increased histidine decarboxylase activity in the lung and spleen but not in plasma. Literature is cited to show that the RES "is altered by similar types of stress and by histamine."

Letheby, B. A., Davis, R. B., Larsen, A. E.: "The effect of major surgical procedures on plasma and platelet levels of factor XIII." *Thromb. Diath. Haemorrh.* **31**: 20-29 (1974). H87,866/74

+Age. Rinfret, A. P., Hane, S.: "Depletion of adrenal ascorbic acid following stress in the infant rat." *Endocrinology* **57**: 497-499 (1955). B29,292/55

In four- to seven-day-old rats, adrenal ascorbic acid depletion in response to a stressor (laparotomy) is the same as in more mature animals and occurs between two and six hours following the initiation of stress.

Franks, R. C.: "Urinary 17-hydroxycorticosteroid and cortisol excretion in childhood." *J. Clin. Endocrinol. Metab.* **36**: 702-705 (1973). H68,183/73

The increase in urinary corticoid excretion is approximately the same in both adults and children exposed to various stressors, such as cardiac catheterization.

Hollmann, G., Fischer, A., Körner, J.: "Besonderheiten der Pathophysiologie des Operationstraumas im Kindesalter" (Peculiarities of the pathophysiology of surgical trauma in children). *Münch. Med. Wochenschr.* **116**: 1213-1218 (1974). H88,808/74

In children undergoing major operations the sympathetic adrenergic response to stress was more manifest than in adults, and while the plasma cortisol levels often showed little or no rise, indirect metabolic reactions suggested that excess aldosterone production occurs in response to a special need at an early age (20 refs.).

+Anesthesia. Virtue, R. W., Helmreich, M. L., Gainza, E.: "The adrenal cortical response to surgery. I. The effect of anesthesia on plasma 17-hydroxycorticosteroid levels." *Surgery* **41**: 549-566 (1957). C36,876/57

In patients, various anesthetics (ether, thiopental and so on) produce different de-

gresses of 17-OHCS discharge, and subsequent surgical operations are always highly effective in this respect.

Brunt, E. E. van, Ganong, W. F.: "The effects of preanesthetic medication, anesthesia and hypothermia on the endocrine response to injury." *Anesthesiology* **24**: 500-514 (1963). E23,121/63

Detailed review of the literature on the influence of preanesthetic medication and hypothermia upon the stressor effects of surgical injuries.

Purves, H. D., Sirett, N. E.: "Time course for corticotrophin release from ectopic pituitary grafts." *Endocrinology* **83**: 1377-1380 (1968). H5,737/68

Tourniquet shock produces an ACTH discharge in rats even when they are under pentobarbital anesthesia.

+Temperature. Brunt, E. E. van, Ganong, W. F.: "The effects of preanesthetic medication, anesthesia and hypothermia on the endocrine response to injury." *Anesthesiology* **24**: 500-514 (1963). E23,121/63

Detailed review of the literature on the influence of preanesthetic medication and hypothermia upon the stressor effects of surgical injuries.

Markley, K., Smallman, E., Thornton, S. W.: "The effect of environmental temperature on mortality and metabolism after burn and tourniquet trauma." *Fed. Proc.* **31**: 817 (1972). H53,564/72

An environmental temperature of 31°C significantly reduced the mortality rate of mice after burn and tourniquet trauma.

Markley, K., Smallman, E., Thornton, S. W., Evans, G.: "The effect of environmental temperature and fluid therapy on mortality and metabolism of mice after burn and tourniquet trauma." *J. Trauma* **13**: 145-160 (1973). J1,495/73

Partially shaved and congenitally hairless mice survive burn and tourniquet trauma better when kept at 31°C than at 25°C.

+Season. Ankier, S. I., Dawson, W., Karady, S., West, G. B.: "Seasonal variation in the resistance of rats." *J. Pharm. Pharmacol.* **17**: 187-188 (1965). G26,781/65

In the rat, traumatic (Noble-Collip drum) and tourniquet shock elicited greater mortality in November than in June or July. The

cause of this seasonal variation in stress resistance could not be determined.

+Diet. Cuthbertson, D. P.: "Physical injury and its effects on protein metabolism." In: Munro, H. N. and Allison, J. B., *Mammalian Protein Metabolism*, Vol. 2, pp. 373-414. New York and London: Academic Press, 1964. G79,175/64

Review on the effect of stress upon protein metabolism. In man, protein loss within ten days of physical injury may amount to about 12 percent of the total body protein. In general, there is a catabolic loss during the first ten days and a maximum at about the third day with a secondary peak on the eighth day. With regard to dietary treatment, most observers hold that "during the first few days following the injury in the previously adequately nourished person it is probably unwise to push the intake of a well-balanced diet beyond appetite as this may fail during this early postinjury phase in severe injuries. Further, kidney function may not be normal for a day or two. Thereafter the patient should be encouraged, but not forced, to take as much as he can of a well-balanced diet, relatively rich in protein."

Sakai, S.: "Effect of protein content of rat diet on amount of corticosterone in tooth ex-

traction." *Folia Pharmacol. Jap.* **68**: 66-72 (1972) (Japanese). H79,322/72

In rats on a low protein diet, the adrenals are comparatively small but show a pronounced increase in size during the stress of tooth extraction, which is ineffective in this respect in controls given normal amounts of protein.

+Genetics. James, V. H. T., Horner, M. W., Moss, M. S., Rippon, A. E.: "Adrenocortical function in the horse." *J. Endocrinol.* **48**: 319-335 (1970). H32,502/70

In the horse, surgical trauma or hypoglycemia increases plasma cortisol whereas exercise is much less effective in this respect. The cortisol variations are not necessarily associated with changes in the eosinophil count. "It is concluded that the mechanisms of control of adrenocortical function in the horse are not dissimilar to those described for other mammalian species."

Halevy, S., Altura, B. M.: "Sex and genetics as factors influencing resistance to traumatic shock." *Fed. Proc.* **33**: 298 (1974). H84,061/74

Certain "strains of mice could be used as models to explore further the roles of sex and genetics in resistance to traumatic shock."

Drugs

In this section, the stressor and conditioning effects of drugs will be enumerated conjointly in alphabetic order. When considered to be convenient for comparative purposes, class names, marked with asterisks (for example, *Anesthetics, *Tranquilizers), will be used in the alphabetic order of their class designations. This was done particularly whenever the same paper discussed several members of the same class; unnecessary repetition is avoided by conjoint grouping.

Most of the data in this section do not lend themselves to comparative evaluation in the form of an introduction, and so, for individual findings, the reader is referred to the abstracts. Whenever two or more drugs are combined, data on the treatment are listed under each drug heading.

Amphenone-induced adrenal hypertrophy is "sometimes" inhibited by destruction of the ME, whereas posterior hypothalamic lesions do not affect ACTH secretion although they curtail TTH production. This is important, since it furnishes additional evidence to support the view that the regulation of ACTH and TTH depends upon distinct centers, only the former being located in the ME.

In hypophysectomized rats with several ectopic adenohypophyseal grafts, amphenone still causes adrenal enlargement, presumably through depression of corticoid production. Hence, these pituitary grafts must remain subject to corticoid feedback control, at least to some extent.

Amphetamine, cf CNS Stimulants

Anesthetics differ in their ability to produce an alarm reaction, particularly a corticoid discharge. However, preanesthetic medication and anesthesia never appear to suffice for a complete inhibition of additional ACTH release following subsequent surgical intervention. In general, ether stimulates, whereas pentobarbital inhibits increased ACTH secretion resulting from trauma, but in dogs with isolated pituitaries (bilateral decortication), this barbiturate no longer depresses corticoid excretion; indeed, it appears to have an inverse augmenting effect.

Preliminary observations suggest that STH secretion in rats is diminished by ether anesthesia.

In rats with hypothalamic-pituitary islands, the high resting plasma corticosterone levels are further elevated by ether, but this response is blocked by pentobarbital. Yet the latter allegedly fails to prevent ACTH release after trauma.

Pentobarbital anesthesia blocks the stress-induced stimulation of the hypothalamus-hypophysis-adrenal axis. This and other barbiturates are frequently used, therefore, as "antistress agents." It has been claimed that even fatal doses of barbiturates fail to produce an adrenal reaction in the rat. However, here again, conditioning circumstances appear to influence the results, since the findings of various investigators were by no means uniform, some having claimed that, in dogs, pentobarbital fails to block an increased corticoid response after whole body vibration or exposure to trauma. Still, the majority of observations suggest that, under usual conditions, barbiturates differ essentially in this respect from other anesthetics, especially ether, which causes a marked ACTH discharge and is often used as a standard stressor agent. This fact is of special importance in connection with the hypothesis according to which, at least in man, stressor effects are invariably mediated through emotional arousal that evidently becomes impossible under anesthesia. It is undoubtedly true, however, that moderate treatment with nervous depressants, particularly neuroleptanesthesia and tranquilizers, tends to counteract the stressor effect of emotional arousal.

When administered intraperitoneally, ketamine, a centrally acting nonbarbiturate anesthetic, raises plasma corticosterone levels in the rat; this effect can be prevented by hypophysectomy or dexamethasone, but only slightly or not at all by atropine, phentolamine, propranolol or haloperidol. Presumably, the response to ketamine is mediated through facilitatory β -adrenergic and/or dopaminergic pathways. The drug also predisposes rats to restraint ulcers.

Antiadrenergics. β -adrenergic blocking agents diminish the tachycardia produced by automobile driving without affecting performance. On the other hand, the rise in FFA and triglycerides noted in people watching exciting films is not prevented by β -blockade, presumably because it is mediated through STH or other hormones causing lipolysis.

The tachycardia, extrasystoles and other unpleasant emotional side effects that develop in some persons when addressing an audience can be abolished by β -adrenergic blocking agents.

In man, the tachycardia produced by increased gravity is diminished by propranolol

but subjective gravity tolerance is maintained. There is some evidence that propranolol also suppresses endogenous renin release in response to various stressors. This effect might play some role in its antihypertensive action.

In adrenalectomized rats, resistance to formalin, hemorrhage, forced muscular exercise and cold was enhanced by various autonomic blocking agents. Perusal of the pertinent literature leaves the definite impression that these drugs offer great promise as "antistress agents," at least under certain conditions.

Anticholinergics such as atropine can produce an alarm reaction in the rat when administered in large doses. Yet, in adrenalectomized rats, resistance to various stressors is increased by autonomic blocking agents, including atropine. Apparently, in the absence of adrenals, autonomic blockade is beneficial. Stress ulcers produced in the rat by immersion in cold water can be prevented by atropine and other anticholinergic agents, although this effect may be associated with ulcer formation in the proventriculus.

Antihistamines. Various antihistaminics have been shown not to interfere significantly with the discharge of adrenal ascorbic acid during stress.

Asiaticoside has recently been claimed to be an "antistress agent," but the few relevant observations are still badly in need of confirmation on a larger scale.

Cannabis allegedly may either inhibit stress-induced corticosterone release in the rat, or actually cause stress reactions, depending upon conditioning circumstances and particularly dosage.

CNS Stimulants. Amphetamine—like various other stressors—depletes the rat brain of its NEP stores but does not significantly affect dopamine concentrations. The drug enhances the toxicity of several other stressors. In mice, radioamphetamine accumulates in synaptic particles of the brain, a response allegedly increased by the stress of isolation.

Among the CNS stimulants, amphetamine has received the greatest attention. It has been claimed that various stressors increase its toxicity, perhaps through the depletion of brain NEP. On the other hand, it appears to augment the 5-HT content of the brain stem. However, the pertinent literature is far from unanimous.

Chlorpromazine does not inhibit ACTH release in surgical shock or following EP injection; in fact, the drug may increase ACTH secretion by itself. Presumably, the response depends upon experimental conditions since some investigators obtained opposite results. The circadian plasma corticoid variations, as well as the stress ulcers produced by restraint in the rat, are inconstantly affected by chlorpromazine.

Colchicine elicits extremely severe manifestations of the alarm reaction including adrenal enlargement and thymicolympathic atrophy, but these effects are prevented by adrenalectomy and presumably mediated through the suprarenals.

Cysteamine produces selective duodenal ulcers in the rat. These serve as a good model for the testing of antiulcer agents, also effective against stress ulcers in man. It is not known, however, why cysteamine is particularly conducive to duodenal ulcers rather than to the gastric lesions characteristic of stress. Additional data on cysteamine-induced ulcers, especially in the study of antiulcer drugs, will be found in the section devoted to stress ulcers in the chapter on Diseases of Adaptation.

Electrolytes, Water, Osmotic Pressure. Various electrolytes, particularly if they produce changes in osmotic pressure, are highly potent stressors.

Ethanol, especially if consumed in large doses, is a typical alarming stimulus. Chronic

alcoholics allegedly drink most when stress and "socialization" coincide. In dogs, mortality following repeated hemorrhage is increased by daily gavages of ethanol.

Ethyltryptamine (a MAO inhibitor), in doses which restore blood pressure, prevents the increase in ACTH secretion produced by hemorrhage in dogs. Presumably, inhibition of ACTH secretion is related to the blockade of hypotension. α -*Methyltryptamine* has a similar effect, which is shared by several other pressor amines, but not by MAO inhibitors. In dogs, α -ethyltryptamine also decreases 17-OHCS output after surgical stress. This is true even when "hypothalamic islands" are created; hence, the compound may prevent stimulation of CRF-secreting neurons.

Formaldehyde injections served as stressors in the first experiments on the alarm reaction, and since then have been frequently employed as typical stressors. The lymphopenic effect of formaldehyde injections can be completely blocked by circumscribed lesions in the ME region of the rat hypothalamus.

Glucose given orally can prevent stress ulcer formation in the rat, especially during starvation, which would otherwise sensitize the gastric mucosa to this type of damage. In monkeys, an exaggerated STH response following intravenous glucose is seen during acute infection.

6-Hydroxydopamine, which causes a "chemical sympathectomy," diminishes the resistance of the rat to cold. There is a marked rise in urinary EP but not in NEP because, presumably, the adrenal medulla largely compensates for the loss of sympathetic nerve activity after treatment with this drug.

6-Hydroxydopamine-induced depletion of catecholamines in the rat brain does not significantly affect the pituitary-adrenal system. "These findings raise serious doubts with regard to the theory of the existence of a noradrenergic inhibitory system acting on pituitary-adrenal regulatory processes in the brain."

MAO inhibitors are discussed under the names of the individual compounds.

Methamphetamine (Desoxyephedrine), a CNS stimulant, inhibits the rise of urinary EP excretion in students undergoing examinations. Curiously, this blocking effect is shared by pentobarbital. The circadian variation of plasma corticoid levels is deranged by methamphetamine as well as by chlorpromazine.

Metyrapone increases ACTH discharge through its action upon the adenohypophysis and is therefore currently used to test the ACTH-secreting capacity of this gland. In epileptics treated with diphenylhydantoin, the normal circadian rhythm of ACTH release is maintained, yet they respond poorly to metyrapone, or to the suppression of ACTH secretion by dexamethasone as a result of deranged feedback controls. In Cushing's syndrome, urinary 17-OHCS excretion as well as plasma ACTH activity are inconsistently influenced by metyrapone.

Morphine was used as one of the first stressors in the original description of the alarm reaction. However, for this purpose, very large doses had to be given. Smaller amounts of it block ACTH secretion induced by various stressors, including histamine, EP, vasopressin and laparotomy; this is true even after unilateral adrenalectomy. On the other hand, the effect of exogenous ACTH is not blocked by morphine, showing that the drug does not interfere directly with adrenocortical reactivity. The blockade of ACTH secretion by morphine is so constant that it has even been used as a basis for the bioassay of CRF which overcomes this blockade. Although chlorpromazine and reserpine may also inhibit ACTH secretion, only the action of morphine is striking and consistent.

Nicotinic acid prevents the elevation in plasma FFA and triglycerides induced in man by emotional stressors, but not the increase in catecholamine elimination and the associated tachycardia and hypertension. In rats, gastric ulcers produced by restraint are more effectively inhibited by nicotinic acid than by chlorpromazine.

PCPA (p-Chlorophenylalanine), a potent tryptophan hydroxylase inhibitor, diminishes brain 5-HT in rats. A number of experiments suggest that "serotonergic" neurons affected by PCPA play an important part in responses of the hypothalamus-hypophysis-adrenal system during stress and the circadian cycle. The volitional increase in ethanol intake is likewise enhanced in rats by PCPA.

Reserpine curtails not only anxiety and fear but also the associated 17-OHCS rises in plasma and urine. On the other hand, large doses of reserpine produce a transient elevation of 17-OHCS levels and hypersecretion of ACTH concurrently with a lowering of brain NEP and 5-HT. At the same time, the ACTH content of the pituitary is sufficiently depleted to prevent a detectable discharge in response to stressors.

Reserpine decreases body temperature in the rat by diminishing heat production rather than by increasing heat loss. Restraint further augments this type of hypothermia.

In rats, reserpine, like dexamethasone or cortisol implants into the ME, inhibits the compensatory hypertrophy of the remaining adrenal after unilateral suprarenalecotomy. However, reserpine implanted into the ME or injected subcutaneously shows no evidence of substituting for glucocorticoids in the feedback regulation of ACTH secretion.

In hares, fear causes regressive changes in the internal nuclear habenular ganglion which can be prevented by reserpine. This was taken to suggest that the "habenular-pineal complex has an important role in the neuroendocrinology of the general adaptation syndrome." EM studies have revealed an increase in electron-dense large granules (presumably carriers of neurohypophyseal hormones) and a decrease in small granules (carriers of catecholamines) in the ME axons of the rat after reserpine treatment.

Reserpine enhances the *in vivo* toxicity of various stressors under most experimental conditions. Large doses can produce stress ulcers in the rat, especially at low surrounding temperatures. These will be discussed at length in the section on the experimental Diseases of Adaptation.

Extensive studies with various *tranquillizers* in psychiatric patients have already been reported in connection with the individual drugs of this group, and complex comparative investigations will have to be consulted in the original publications cited herein.

Drugs

(See also our earlier stress monographs, p. xiii)

Actinomycin. (See Antibiotics)

Adenosine Monophosphate (AMP), Adenosine Diphosphate (ADP), Adenosine Triphosphate (ATP). Rotondo, G.: "Sull'impiego dell'acido adenosintrifosforico e della cocarbossilasi in piloti affetti da lieve o iniziale fatica di volo" (The use of adenosine triphosphate and cocarboxylase in pilots suffering from light or initial flying fatigue).

Riv. Med. Aeronaut. Spaz. **27:** 172-192 (1964).
G19,344/64

Flying fatigue in jet pilots is ascribed to the exhaustion of adaptation energy. Treatment with a combination of ATP and co-carboxylase is beneficial (19 refs.).

Adrenergic Blocking Agents. (See Anti-adrenergics)

Alloxan. (See also Insulin, Diabetes) Kraus, S. D.: "Impairment of the pituitary-adrenal response to acute stress in al-

loxan diabetes." *Acta Endocrinol.* (Kbh.) **54**: 328-334 (1967). F77,713/67

Ivanova, I. I., Lapshina, V. F., Tsaplin, V. M.: "Corticosterone content in the peripheral blood and adrenal glands during stress in rats with alloxan diabetes." *Probl. Endokrinol.* **20** No. 3: 94-97 (1974) (Russian). H92,322/74

In rats, alloxan diabetes did not significantly influence the typical stress reaction to trauma. The rats showed adrenal enlargement, thymus involution and elevated corticosterone levels in plasma and the adrenals.

Altrinolol. (See **Antiadrenergics**)

Aminoglutethimide. Loscalzo, B., Nisticò, G., Preziosi, P.: "A possible dissociation of ACTH effects on the adrenal glands as revealed by aminoglutethimide." *Pharmacol. Res. Commun.* **2**: 55-62 (1970).

G80,104/70

In rats, aminoglutethimide inhibits an increase in plasma corticosterone levels after stress (swimming in cold water until exhaustion). The compound also dissociates the effect of ACTH (following failure of the negative feedback mechanism and hypophyseal activation by stress) at the adrenocortical level in that a decrease in adrenal ascorbic acid and an increase in adrenal cholesterol occur without any relation to enhanced corticosterone synthesis.

Greer, M. A., Allen, C. F.: "Failure to detect excessive stress-induced adrenal corticosterone secretion following amino-glutethimide withdrawal in the rat." *Endocrinology* **91**: 600-602 (1972). H58,083/72

Aminoglutethimide is chemically related to amphenone and inhibits corticosterone synthesis, presumably by depressing conversion of cholesterol to pregnenolone. In rats, the "plasma corticosterone concentration was measured 20 min after an ether stress before and on various days during and after amino-glutethimide feeding. There was a significant depression of the corticosterone concentration within two days after starting the experimental diet which persisted throughout the period of drug administration. Within 1-2 days after drug withdrawal, plasma corticosterone response to ether had returned to control levels. There was no supranormal response up to 8 days after drug withdrawal, indicating that a marked increase in available cholesterol in the adrenal does not per se lead to an increase in hormone secretion."

Amphenone. (See also **Aminoglutethimide**) Greer, M. A., Erwin, H. L.: "Evidence of separate hypothalamic centers controlling corticotropin and thyrotropin secretion by the pituitary." *Endocrinology* **58**: 665-670 (1956). C14,624/56

In rats, destruction of the ME "sometimes" inhibited amphenone-induced adrenal hypertrophy whereas posterior hypothalamic lesions did not significantly affect ACTH secretion, but did curtail TTH production. Presumably, the centers for ACTH and TTH excretions are distinct and the former is limited to the ME.

Hertz, R.: "Gonadotropin and adrenocorticotropic from rat pituitary homografts as manifested by host response to chorionic gonadotropin and amphenone." *Endocrinology* **66**: 842-844 (1960). C87,506/60

In hypophysectomized rats bearing four adenohypophyseal grafts under the renal capsule, amphenone caused adrenal enlargement that was lacking in hypophysectomized controls. "Since the adrenomegalic response to amphenone is mediated through suppression of corticoid production by the rat adrenal, these pituitary grafts apparently also maintain a degree of reciprocal functional relationship with the adrenal cortex."

Amphetamine. (See **CNS Stimulants**)

***Anesthetics and Analgesics.** (See also under the names of specific anesthetics and analgesics) Ronzoni, E.: "Sodium pentobarbital anesthesia and the response of the adrenal cortex to stress." *Am. J. Physiol.* **160**: 499-505 (1950). B47,024/50

In rats, *pentobarbital* anesthesia blocked the depletion of adrenal ascorbic acid and the hyperglycemia normally produced by cold. "With hemorrhage or heat as the form of stress, anesthetic sufficient to prevent the normally observed increase in blood glucose failed to influence the lowering of adrenal ascorbic. Apparently even light anesthesia is sufficient to inhibit epinephrine release due to this mild form of stimulation."

Heldt, T. J.: "Effect of agents inducing deliria on the course of certain bodily reactions to stress." In: Wolff, H. G., Wolf, S. G. Jr. et al., *Life Stress and Bodily Disease*, pp. 477-519. Baltimore: Williams & Wilkins, 1950. B51,923/50

Gori, E.: "Les hypnotiques et le stress" (Hypnotic drugs and stress). *20e Congr. Int.*

Physiol., pp. 357-358. Brussels, July 30-August 4, 1956. C23,393/56

Even fatal doses of *barbiturates* fail to produce an alarm reaction (adrenal ascorbic acid depletion) in the rat, and they actually inhibit the stressor effects of various agents. On the other hand, many hypnotics and anesthetics stimulate ACTH secretion and may thereby overcome their own antistress actions which might be due to depression of the reticular formation. [The brief abstract does not lend itself to critical analysis (H.S.).]

Virtue, R. W., Helmreich, M. L., Gainza, E.: "The adrenal cortical response to surgery. I. The effect of anesthesia on plasma 17-hydroxycorticosteroid levels." *Surgery* 41: 549-566 (1957). C36,876/57

In patients, various anesthetics (*ether*, *thiopental*, and so on) produce different degrees of 17-OHCS discharge, and subsequent surgical operations are always highly effective in this respect.

Hammond, W. G., Vandam, L. D., Davis, J. M., Carter, R. D., Ball, M. R., Moore, F. D.: "Studies in surgical endocrinology. IV. Anesthetic agents as stimuli to change in corticosteroids and metabolism." *Ann. Surg.* 148: 199-211 (1958). C57,405/58

"General anesthesia produced by *Pentothal*, *nitrous oxide* and *d-tubo-curare* in any combination was associated with significant changes in blood or urinary 17-hydroxycorticoid values.... Operation under Pentothal-N₂O-d-tubo-curare anesthesia was followed by an elevation of the free blood 17-OHCS, but the magnitude of the rise was not as great as that seen with operation under ether."

Brunt, E. E. van, Ganong, W. F.: "The effects of preanesthetic medication, anesthesia and hypothermia on the endocrine response to injury." *Anesthesiology* 24: 500-514 (1963). E23,121/63

Detailed review of the literature on the influence of *preanesthetic medication* and hypothermia upon the stressor effects of surgical injuries.

Matsuda, K., Duyck, C., Kendall, J. W. Jr., Greer, M. A.: "Pathways by which traumatic stress and ether induce increased ACTH release in the rat." *Endocrinology* 74: 981-985 (1964). F12,792/64

In rats, following removal of all prosencephalon anterior to the superior colliculus, with an isolated ME, stalk and pituitary left intact, there is still ACTH release (corti-

costerone in adrenal effluent) in response to *ether* anesthesia with or without additional traumatic stress (fracture of foreleg). However, after *Nembutal* anesthesia traumatic stress is no longer active in this respect. Bone fracture distal to a section of the spinal cord in otherwise intact rats also fails to raise adrenal cortical secretion under Nembutal but not under ether anesthesia. "Ether apparently directly stimulates the median eminence to cause increased ACTH release. Traumatic stress induces ACTH release through ascending neural pathways feeding to the hypothalamus through the dorsal mesencephalon."

Blivaiss, B. B., Litta-Modignani, R., Priede, I.: "Plasma 17-hydroxycorticosteroids in dogs after whole body vibration." In: Martini, L. and Pecile, A., *Hormonal Steroids. Biochemistry, Pharmacology, and Therapeutics*, Vol. 2, pp. 511-516. New York and London: Academic Press, 1965.

E5,495/65

In dogs anesthetized with *pentobarbital*, whole body vibration still causes a "stress-like response" in that it increases plasma 17-OHCS elimination although this reaction is even more pronounced in nonanesthetized animals. Evidently, emotional factors are important but consciousness is not indispensable for typical adrenal stress reactions.

Egdahl, R. H.: "Studies on the effect of ether and pentobarbital anesthesia on pituitary adrenal function in the dog." *Neuroendocrinology* 1: 184-191 (1966).

F65,750/66

In dogs, the rise in plasma 17-OHCS caused by the trauma of adrenal vein cannulation was the same under ether and *pentobarbital* anesthesia. Neither anesthetic altered cortical sensitivity to ACTH. Ether was a potent but variable stimulus of corticoid secretion, and its effect could be depressed by concurrent administration of pentobarbital. In dogs with isolated pituitaries (bilateral decortication), this barbiturate failed to depress cortical hypersecretion and appeared to have an inverse, increasing effect.

Schalch, D. S., Reichlin, S.: "Plasma growth hormone concentration in the rat determined by radioimmunoassay: influence of sex, pregnancy, lactation, anesthesia, hypophysectomy and extrasellar pituitary transplants." *Endocrinology* 79: 275-280 (1966).

F69,338/66

In hypophysectomized rats, plasma STH levels become undetectable and intraocular pituitary transplants fail to raise them. Brief periods of *ether* anesthesia decrease STH only in male rats.

Dobkin, A. B., Byles, P. H., Neville, J. F. Jr.: "Neuroendocrine and metabolic effects of general anaesthesia and graded haemorrhage." *Can. Anaesth. Soc. J.* **13**: 453-475 (1966). G41,075/66

In dogs, various parameters of the stress reaction were compared following anaesthesia induced by different agents in combination with severe bleeding, and after pretreatment with methylprednisolone and ampicillin. Individual parameters of the stress response varied depending upon the *anesthetic* used. "It is likely that the rapid recovery from the stress of the combination of haemorrhage and general anaesthesia may be attributed to the use of a relatively large dose of the corticoid and antibiotic drugs." [Lack of adequate controls makes it difficult to identify the relative role of each factor in this complicated procedure (H.S.).]

Greer, M. A., Rockie, C.: "Inhibition by pentobarbital of ether-induced ACTH secretion in the rat." *Endocrinology* **83**: 1247-1252 (1968). H5,714/68

In rats, ether anesthesia stimulated ACTH release, apparently acting through the ME. *Pentobarbital* anesthesia actually blocked this release, as indicated by plasma corticosterone levels. Rats with hypothalamic-pituitary islands (Halász knife) had high resting plasma corticosterone concentrations which were further increased by ether. Pentobarbital also blocked this response. Presumably, "pentobarbital acts on the basal hypothalamus to prevent ether from inducing ACTH release but does not prevent ACTH release following trauma."

Purves, H. D., Sirett, N. E.: "Time course for corticotrophin release from ectopic pituitary grafts." *Endocrinology* **83**: 1377-1380 (1968). H5,737/68

In rats, tourniquet shock increased ACTH discharge even under *pentobarbital* anesthesia.

Shephard, D. A. E.: "The anxious surgical patient and anaesthesia." *N.S. Med. Bull.* **47**: 107-111 (1968). G58,805/68

Practical hints on ways to avoid the stressor effect of *anaesthesia* in anxious patients.

Oyama, T., Saito, T., Isomatsu, T., Samejima, N., Uemura, T., Arimura, A.: "Plasma

levels of ACTH and cortisol in man during *diethyl ether* anaesthesia and surgery." *Anesthesiology* **29**: 559-564 (1968).

G57,525/68

Jégo, P., Lescoat, G., Beraud, G., Maniez, J.: "Etude des modalités de réponse du complexe hypothalamo-hypophysio-surrénalien à l'agression par l'éther chez le rat: cas d'une injection intraperitoneale" (Study on the responsiveness of the hypothalamo-hypophysio-adrenal axis to stress by ether in the rat: effects of intraperitoneal injection). *C.R. Soc. Biol. (Paris)* **164**: 2117-2121 (1970). H41,303/70

The increase in blood corticosterone produced in rats by *ether* is diminished by previous *pentobarbital* anaesthesia. However, intraperitoneal injection of ether causes marked rises in blood corticosterone in pentobarbital-anesthetized females, but not in males.

Theye, R. A.: "Effects of *halothane*, anoxia, and hemorrhage upon canine whole-body, skeletal muscle, and splanchnic excess lactate production." *Anesthesiology* **35**: 394-400 (1971) (18 refs.). J20,012/71

Dechezleprêtre, S., Lechat, P.: "Influence du jeûne, du stress et de la narcose sur le taux de corticostérone plasmatique chez le rat" (Effect of fasting, stress and anaesthesia on plasma corticosterone levels in the rat). *Arch. Sci. Physiol.* **25**: 247-259 (1971). G85,426/71

In rats, *ether*, *chloral*, *hydroxydione* and *ethylurethane* considerably increase blood corticosterone levels. Since pentobarbital is comparatively ineffective in this respect, it is a suitable anesthetic for experiments in which a virtually normal baseline of blood corticoids is desirable.

Tarhan, S., Fulton, R. E., Moffitt, E. A.: "Body metabolism during general anaesthesia without superimposed surgical stress." *Anesth. Analg. (Cleve.)* **50**: 915-923 (1971). J11,008/71

Patients briefly anesthetized for renal arteriograms by four combinations of agents (*halothane*, *nitrous oxide*, *thiopental* and *Innovar*) showed no evidence of stress, judging from plasma STH, FFA and glucose levels (26 refs.).

Lidbrink, P., Corrodi, H., Fuxé, K., Olson, L.: "Barbiturates and meprobamate: decreases in catecholamine turnover of central dopamine and noradrenaline neuronal sys-

tems and the influence of immobilization stress." *Brain Res.* (Amst.) **45**: 507-524 (1972). G95,413/72

Buchel, L., Prioux-Guyonneau, M., Liblau, L., Murawsky, M.: "Influence de la contrainte du rat blanc sur l'activité, la pénétration et le métabolisme de l'hexobarbital et du barbital" (Influence of restraint on the activity, penetration and metabolism of hexobarbital and barbital in white rats). *Thérapie* **27**: 609-625 (1972). G92,849/72

"The potentiation of the hypnotic effects, increases of the sleeping time with *hexobarbital*, shortening of the latent period with barbital, in relation with short or long lasting restraint in rats, are attributable to two different mechanisms: inhibition of hexobarbital metabolism; increase of barbital penetration into the brain."

Dobkin, A. B., Pieloch, P. A.: "The metabolic effects of neuroleptanesthesia." *Int. Anesthesiol. Clin.* **11**: 155-169 (1973).

J9,286/73

Brief résumé of the literature and personal observations on the metabolic changes associated with anesthesia, particularly *neuroleptanesthesia* in man. The alterations in blood sugar, plasma cortisol, catecholamines and so on are clearly characteristic of systemic stress. Furthermore, in the case of concurrent surgical interventions, "balanced anesthesia, with or without the neuroleptic component, does not block the stress response. Associated rises in blood sugar, plasma cortisol, and catecholamines during anesthesia and surgery appear to be well documented" (31 refs.).

Cheney, D. H., Slogoff, S., Allen, G. W.: "Ketamine-induced stress ulcers in the rat." *Anesthesiology* **40**: 531-535 (1974).

J13,522/74

In rats, restraint produced stress ulcers whereas *ketamine* alone, at the dose levels given, did not although it did increase the incidence of restraint-induced ulcers from 35 percent to almost 100 percent. This sensitization was counteracted by phenoxybenzamine and halothane, "suggesting that the action of ketamine is mediated by vasoconstriction. Antihistamine pretreatment with promethazine was without effect."

Fahringer, E. E., Foley, E. L., Redgate, E. S.: "Pituitary adrenal response to ketamine and the inhibition of the response by catecholaminergic blockade." *Neuroendocrinology* **14**: 151-164 (1974). H86,423/74

Ketamine, a centrally acting nonbarbiturate anesthetic given intraperitoneally, caused a rise in the blood corticosterone content of rat plasma which was abolished by hypophysectomy or dexamethasone. This response was only slightly altered by pretreatment with atropine or phentolamine but significantly diminished by propranolol or haloperidol. The authors assume that the "response to ketamine is mediated through a facilitatory β -adrenergic and/or dopaminergic pathway or some hybrid thereof, and that ketamine is a convenient and useful agent for testing pituitary adrenal responsiveness in the rat."

Roizen, M. F., Moss, J., Henry, D. P., Kopin, I. J.: "Effects of halothane on plasma catecholamines." *Anesthesiology* **41**: 432-439 (1974). J17,763/74

Cunitz, G., Plötz, J., Michel, B.: "Untersuchungen über den Einfluss der Narkose auf das Hypophysenvorderlappen-Nebennierenrinden-System anhand von Ascorbinsäurebestimmungen" (Investigations on the influence of *anesthesia* on the anterior pituitary gland-adrenocortical system using ascorbic acid determinations). *Anaesthetist* **23**: 520-524 (1974). J21,846/74

Nakashima, A., Koshiyama, K., Uozumi, T., Monden, Y., Hamanaka, Y., Kurachi, K., Aono, T., Mizutani, S., Matsumoto, K.: "Effects of general *anesthesia* and severity of surgical stress on serum LH and testosterone in males." *Acta Endocrinol. (Kbh.)* **78**: 258-269 (1975). H96,576/75

***Antiadrenergics.** Goldstein, M. S., Ramey, E. R., Fritz, I., Levine, R.: "Reversal of effects of stress in adrenalectomized animals by autonomic blocking agents. Use of atropine, Banthine and Dibenamine." *Am. J. Physiol.* **171**: 92-99 (1952). B75,440/52

In adrenalectomized rats resistance to formalin, hemorrhage, forced muscular exercise and cold was increased by autonomic blocking agents such as *atropine*, *Banthine*, *Dibenamine* and *Thephorin*. Apparently, in the absence of adrenals, blockade of autonomic stimuli is beneficial.

Eliasch, H., Rosen, A., Scott, H. M.: "Systemic circulatory response to stress of simulated flight and to physical exercise before and after propranolol blockade." *Br. Heart J.* **29**: 671-683 (1967). G50,658/67

Heart rate, blood pressure and cardiac output increased in pilots during a Link

trainer simulated flight, and also after intense physical exercise on a bicycle ergometer. Comparisons with similar tests after *propranolol* administration "indicate that beta adrenergic receptor activity is extensively involved in the circulatory reaction to emotional stress. In contrast, this activity appears to be involved but less essential in the achievement of the circulatory adjustments during moderate physical exercise."

Goldman, V., Comerford B., Hughes, D., Nyberg, G.: "Effect of β -adrenergic blockade and alcohol on simulated car driving." *Nature* **224**: 1175-1178 (1969). H19,740/69

The β -adrenergic blocking agent *alprenolol* diminishes the tachycardia produced by an exciting ride in a fast roller coaster or a simulated car driving machine without significantly affecting driving performance.

Pettinger, W. A., Augusto, L., Leon, A. S.: "Alteration of renin release by stress and adrenergic receptor and related drugs in unanesthetized rats." *Adv. Exp. Med. Biol.* **22**: 105-117 (1972). G94,419/72

Renin release, noted after exposure to various stressors, can be influenced by diverse drugs. "The beta-adrenergic blocking drug *propranolol* suppressed endogenous release of renin and inhibited renin release induced by stresses of swimming and anesthesia... Suppression of endogenous renin release by *propranolol* could play a role in the antihypertensive properties of this drug in man."

Palmer, B.: "The influence of stress on the survival of experimental skin flaps. A study on rats." *Scand. J. Plast. Reconstr. Surg.* **6**: 110-113 (1972). G99,625/72

In rats with very long skin flaps that normally undergo partial necrosis, stress (restraint) distinctly diminished skin survival, but this could be inhibited by α -adrenergic blocking agents presumably because they prevent vasoconstriction. [Since the skin flap, even at the end farthest removed from its attachment to normal skin, was equivalent to an autotransplant which usually heals without necrosis in the absence of all vascular connections, it is difficult to understand why this was not the case here (H.S.).]

Gorizontov, P. D., Belousova, O. I., Zimin, I. I.: "Role of adrenalin and exclusion of α -receptors in reactions of the hemopoietic organs to stress." *Biull. Eksp. Biol. Med.* **73** No. 12: 23-26 (1972) (Russian).

J20,143/72

Clasing, D., Machtens, E.: "The effect of beta adrenergic blocking agents on the heart rate during psychic stress." *Proc. Biotelemetry Int. Symp.*, pp. 246-250 (1972).

H80,196/72

Carruthers, M., Taggart, P.: "Vagotonicity of violence: biochemical and cardiac responses to violent films and television programmes." *Br. Med. J.* August 18, 1973, pp. 384-389. H74,499/73

Description of the changes in blood EP, glucose, FFA, triglycerides and STH that occurred in men and women watching films and television programs depicting violence, humor or suspense. "Groups of people taken to see two particularly violent films showed similar evidence suggesting vagal overactivity, together with increases in plasma free fatty acids and decreases in triglycerides. As these changes occurred even with β -blockade, it is suggested that they might be caused by non-sympathetically mediated changes in the levels of hormones, such as growth hormone, producing lipolysis."

Taggart, P., Carruthers, M., Somerville, W.: "Electrocardiogram, plasma catecholamines and lipids, and their modification by *oxprenolol* when speaking before an audience." *Lancet* August 18, 1973, pp. 341-346.

H74,091/73

In normal subjects and patients with coronary heart disease, speaking before an audience caused tachycardia (up to 180 per minute), and an increase in plasma catecholamines and FFA. Ectopic heartbeats were noted in about 25 percent of these subjects. A single dose of the β -adrenergic blocker *oxprenolol* suppressed most of the cardiac anomalies in both normal and coronary subjects, although plasma NEP levels were not significantly affected. Presumably, "emotional challenges may produce conspicuous cardiovascular effects, especially in susceptible persons. It is suggested that β -blockade could be used to alleviate the unpleasant symptoms associated with speaking before an audience."

Taylor, S. H., Meenan, M. K.: "Different effects of adrenergic beta-receptor blockade on heart rate response to mental stress, catecholamines and exercise." *Br. Med. J.* November 3, 1973, pp. 257-259.

H77,497/73

In normal people a single oral tablet of *oxprenolol* relieves the tachycardia associated with automobile driving and isoproterenol, whereas exercise tachycardia is substantially

less influenced. "Thus relatively small doses of beta-receptor antagonists will suppress the increase in heart rate induced by mental stress or catecholamines with relatively little effect on the response to everyday exercise. Possibly smaller doses of these drugs would relieve emotionally-induced anginal pain and tachycardia."

Bergamaschi, M., Caravaggi, A. M., Mandelli, V., Shanks, R. G.: "The role of beta adrenoceptors in the coronary and systemic hemodynamic responses to emotional stress in conscious dogs." *Am. Heart J.* **86**: 216-226 (1973). H72,433/73

In dogs, "emotional stress produced by firing a gun increased heart rate, cardiac output, and left ventricular work." The responses were reduced by *propranolol* and *practolol*, and abolished by *alprenolol*.

Winchester, J. F.: "Drug profile: Trasistor." *J. Int. Med. Res.* **2**: 448-457 (1974). H97,640/74

In man, *oxprenolol* is allegedly the most effective β -blocker in simulated emotional stress situations, and can be highly recommended in the treatment of hypertension and angina pectoris.

Bjurstedt, H., Rosenhamer, G., Tydén, G.: "Acceleration stress and effects of propranolol on cardiovascular responses." *Acta Physiol. Scand.* **90**: 491-500 (1974).

J12,120/74

In man, after treatment with *propranolol*, "the heart rate response to increased G at rest averaged 38 percent of that observed without blockade, indicating that G-induced cardioacceleration is predominantly due to sympathetic stimulation." However, subjective gravity tolerance was well preserved; hence, sympathetic chronotropic stimulation of the heart is not essential for the circulatory defense against gravitational stress.

*Antiadrenocortical Compounds. (See *Amphenone, Metyrapone*)

*Antibiotics. Renaud, S.: "Action du stress et de NaCl sur les effets toxiques et bactériostatiques de la néomycine" (Action of stress and NaCl on the toxic and bacteriostatic effects of neomycin). *Presse Méd.* **69**: 281-283 (1961). C94,493/61

Various antibiotics, especially *neomycin*, become particularly pathogenic if applied to rats simultaneously with some stressors. Cer-

tain sodium salts offer protection against this combined treatment.

Arimura, A., Bowers, C. Y., Schally, A. V., Saito, M., Miller, M. C.: "Effect of corticotropin-releasing factor, dexamethasone and actinomycin D on the release of ACTH from rat pituitaries in vivo and in vitro." *Endocrinology* **85**: 300-311 (1969). H15,815/69

Comparative in vivo and in vitro studies on rats given *actinomycin D* to inhibit DNA-dependent RNA synthesis led to the following conclusions: 1) Dexamethasone suppresses the action of CRF at the pituitary level, 2) this dexamethasone blockade does not develop immediately, 3) dexamethasone-blockade of CRF requires a process which involves DNA-dependent RNA synthesis, and 4) the process of ACTH release by CRF does not require RNA synthesis" (34 refs.).

Cannon, R. E., Shane, M. S.: "The effect of antibiotic stress on protein synthesis in the establishment of lysogeny of *Plectonema boryanum*." *Virology* **49**: 130-133 (1972). G92,363/72

Evidence is presented for the establishment of lysogeny in *Plectonema boryanum* by LPP-1D and LPP-2 phycoviruses after treatment of the alga with *chloramphenicol*.

Walton, J. R.: "Indirect consequences of low-level use of antimicrobial agents in animal feeds." *Fed. Proc.* **34**: 205-208 (1975). H98,529/75

In mammals treated with *antimicrobial agents*, "one form of stress may be defined in terms of a disturbance of intestinal flora brought on by relocation, group mixing, change of diet, or travel."

*Anticholinergics. Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* **17**: 234-248 (1936). 36,032/36

First detailed description of the "alarm reaction" characterized by adrenocortical enlargement with acute loss of lipids, thymic-lymphatic atrophy, and decreased body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for 48 hours or more, large doses of *atropine*, morphine, formaldehyde or EP). Adrenalectomy and, to a lesser extent, hypophsectomy prevent the thymus involution. "The changes caused by a drug when it is given for the first time will subside later in spite of the continued administration of this drug," but greatly

shorten survival. Perhaps the adrenal enlargement, loss of body weight and other manifestations of the alarm reaction enable the organism "to meet critical situations more efficiently."

Goldstein, M. S., Ramey, E. R., Fritz, I., Levine, R.: "Reversal of effects of stress in adrenalectomized animals by autonomic blocking agents. Use of atropine, Banthine and dibenamine." *Am. J. Physiol.* **171**: 92-99 (1952). B75,440/52

In adrenalectomized rats resistance to formalin, hemorrhage, forced muscular exercise and cold was increased by autonomic blocking agents such as *atropine*, Banthine, Dibenamine and Thephorin. Apparently, in the absence of adrenals, blockade of autonomic stimuli is beneficial.

Takagi, K., Okabe, S.: "An experimental gastric ulcer of the rat produced with anticholinergic drugs under stress." *Eur. J. Pharmacol.* **5**: 263-271 (1969). H9,358/69

In rats, the stress ulcers produced by immersion in cold water are prevented by *atropine* and other anticholinergic agents, but at the same time another type of ulcer appears in the proventriculus.

***Antihistamines.** Tepperman, J., Rakieten, N., Birnie, J. H., Diermeier, H. F.: "Effect of antihistamine drugs on the adrenal cortical response to histamine and to stress." *J. Pharmacol. Exp. Ther.* **101**: 144-152 (1951). B59,242/51

In rats, various *antihistaminics* (Phenoxyadrine, Benadryl, Pyribenzamine) did not significantly alter adrenal ascorbic acid, but intraperitoneal injection of histamine reduced it remarkably. On the other hand, "pretreatment with an antihistamine drug did not prevent or modify the adrenal ascorbic acid response to the stress of intraperitoneal carbon tetrachloride administration."

Asiaticoside. Ravokatra, A., Loiseau, A., Ratsimamanga-Urverg, S., Nigeon-Dureuil, M., Ratsimamanga, A. R.: "Action de l'asiaticoside (triterpène pentacyclique) retiré de l'Hydrocotyle Madagascariensis sur les ulcères duodénaux créés par la mercaptoéthylamine chez le rat Wistar mâle" (The effects of asiaticoside [pentacyclic triterpene] extracted from Hydrocotyle Madagascariensis on mercaptoethylamine-induced duodenal ulcers in the Wistar male rat). *C. R. Acad.*

Sci. (Paris) **278**: 2317-2321 (1974).

J13,441/74

In rats, cysteamine-induced duodenal ulcers can be prevented by asiaticoside. A similar protective effect is exerted by this compound against peptic ulcers caused by stress.

Atropine. (See **Anticholinergics**)

Barbiturates. (See **Anesthetics and Analgesics**)

Benzene. Bartolini, G., Berti, P.: "Istopatologia del timo di 'Mus ratus albinus' nel benzolismo cronico sperimentale" (Thymus histopathology in "Mus ratus albinus" after chronic experimental benzolism). *Arch. Vecchi Anat. Patol.* **63**: 777-786 (1964).

G32,118/64

Chronic benzol intoxication produces a typical G.A.S. with conspicuous thymus involution in the rat.

Cannabis. "Cannabis and driving skills." *Can. Med. Assoc. J.* **107**: 269-270 (1972). J16,956/72

Retterstøl, N.: "Cannabis og bilkjøring" (Cannabis and car driving). *T. Norske Laegeforen.* **93**: 2121-2122 (1973) (Norwegian). J16,347/73

Pertwee, R. G.: "Tolerance to the effect of Δ^1 -tetrahydrocannabinol on corticosterone levels in mouse plasma produced by repeated administration of cannabis extract or Δ^1 -tetrahydrocannabinol." *Br. J. Pharmacol.* **51**: 391-397 (1974). H92,479/74

"Pretreatment with cannabis extract or Δ^1 -THC can produce tolerance to the effect of Δ^1 -THC on corticosterone levels in mouse plasma and does so without impairing the effect of immobilization stress on corticosterone release. In addition, both the rise in corticosterone plasma levels produced by cannabis or Δ^1 -THC and the development of tolerance to this effect can still take place in the absence of hypothermia."

Klonoff, H.: "Marijuana and driving in real-life situations. The effect of marijuana on driving is bidirectional and dependent on compensatory ability and dose." *Science* **186**: 317-324 (1974). H93,920/74

Kokka, N., Garcia, J. F.: "Effects of Δ^9 -THC on growth hormone and ACTH secre-

tion in rats." *Life Sci.* **15**: 329-338 (1974).

J15,591/74

Δ^9 -Tetrahydrocannabinol (Δ^9 -THC) "acts as a pharmacological stressor of hypothalamo-pituitary function in rats since the same changes in plasma corticosterone and GH concentrations are elicited in response to many stimuli that are commonly of a stressful nature" (23 refs.).

Carbohydrates. (See under names of individual carbohydrates)

Chloramphenicol. (See Antibiotics)

Chlorpromazine. (See also Tranquilizers) Holzbauer, M., Vogt, M.: "The action of chlorpromazine on diencephalic sympathetic activity and on the release of adrenocorticotropic hormone." *Br. J. Pharmacol.* **9**: 402-407 (1954). C7,651/54

In rats, ACTH release following surgical shock or EP injection was not prevented by chlorpromazine which in fact caused some ACTH secretion by itself. These observations contradict certain earlier claims.

Sevy, R. W., Ohler, E. A., Weiner, A.: "Effect of chlorpromazine on stress-induced adrenal ascorbic acid depletion." *Endocrinology* **61**: 45-51 (1957). C37,515/57

In experiments on rats, chlorpromazine did not cause adrenal ascorbic acid depletion but actually inhibited this change when produced by sham adrenalectomy, unilateral adrenalectomy or by EP. The adrenal ascorbic acid depletion elicited by vasopressin or ACTH was not influenced.

DeBias, D. A., Paschkis, K. E., Cantarow, A.: "Effects of chlorpromazine and autonomic nervous system blocking agents in combating heat stress." *Am. J. Physiol.* **193**: 553-556 (1958). C54,401/58

Personal observations and brief review of the literature on the effects of various drugs upon resistance to diverse stressors in intact and adrenalectomized rats. Since different drugs are effective against different stressors, the mechanism of protection must be dissimilar.

Mahfouz, M., Ezz, E. A.: "The effect of reserpine and chlorpromazine on the response of the rat to acute stress." *J. Pharmacol. Exp. Ther.* **123**: 39-42 (1958). C53,654/58

In rats, both chlorpromazine and reserpine inhibit the stressor effect (adrenal ascorbic acid depletion) of cold, heat and hemorrhage

under ether anesthesia. Neither drug prevents the adrenal ascorbic acid depletion caused by ACTH, but may act upon the hypothalamus.

Juszkiewicz, T., Jones, L. M.: "The effects of chlorpromazine on heat stress in pigs." *Am. J. Vet. Res.* **22**: 553-557 (1961).

J10,364/61

As indicated by adrenal ascorbic acid determinations, "chlorpromazine diminishes stressful response of the pituitary-adrenal axis in pigs due to hyperthermia, increases the survival rate at 40°C., and decreases the body weight loss."

Juszkiewicz, T.: "Effects of chlorpromazine, reserpine, and ascorbic acid in resisting heat stress in rats." *Am. J. Vet. Res.* **22**: 537-543 (1961).

J11,417/61

In rats, pretreatment with chlorpromazine, reserpine or ascorbic acid failed to prevent but did somewhat diminish the loss of adrenal ascorbic acid produced by heat (43°C.).

Betz, D., Ganong, W. F.: "Effect of chlorpromazine on pituitary-adrenal function in the dog." *Acta Endocrinol. (Kbh.)* **43**: 264-270 (1963).

D68,211/63

Bohus, B., Endrőczi, E.: "Untersuchungen über die Wirkung von Chlorpromazin auf das Hypophysen-Nebennierenrinden-System bei Ratten" (Studies on the effect of chlorpromazine on the hypophysis-adrenal cortex system in rats). *Endokrinologie* **46**: 126-133 (1964).

F16,012/64

In rats, large doses of subcutaneous chlorpromazine, particularly when injected into the reticular formation of the brain, produced high corticosterone secretion. It was not possible to inhibit the blood corticosterone rise normally caused by stressors (formalin, restraint) through pretreatment with chlorpromazine.

Yamashita, I., Moroji, T., Yamazaki, K., Kato, H., Sakashita, A., Onodera, I., Ito, K., Okada, F., Saito, Y., Tamakoshi, M., Suwa, N.: "Neuroendocrinological studies in mental disorders and psychotropic drugs. I. On the circadian rhythm of the plasma adrenocortical hormone in mental patients and methamphetamine- and chlorpromazine-treated animals." *Folia Psychiatr. Neurol. Jap.* **23**: 143-158 (1969).

G72,651/69

The circadian plasma corticosteroid rhythm was deranged in rats treated with methamphetamine or chlorpromazine.

Lindenbaum, E. S., Diamond, B., Yaryura-Tobías, J. A.: "Nicotinic acid and restraint induced ulcers." *Acta Physiol. Lat. Am.* **23**: 288-292 (1973). J9,059/73

In rats, the gastric ulcers produced by restraint with food and water deprivation are more effectively inhibited by nicotinic acid than by chlorpromazine.

p-Chlorophenylalanine. (See PCPA)

***CNS Stimulants.** (See also Methamphetamine) Weiss, B., Laties, V. G., Blanton, F. L.: "Amphetamine toxicity in rats and mice subjected to stress." *J. Pharmacol. Exp. Ther.* **132**: 366-371 (1961).

D6,968/61

The toxicity of *amphetamine* is increased in rats and mice exposed to aversive electroshock. This effect can be counteracted by chlorpromazine and phenoxybenzamine.

Moore, K. E., Lariviere, E. W.: "Effects of stress and D-amphetamine on rat brain catecholamines." *Biochem. Pharmacol.* **13**: 1098-1100 (1964). G17,075/64

Various stressors enhanced the toxicity of *d-amphetamine*, perhaps through the release of NEP. Among the stressors examined (restraint, swimming, electroshock, sound and so on), only some caused a significant increase in amphetamine toxicity and a decrease in brain NEP. In the latter respect, grid-shocked rats were particularly responsive. The depletion of brain NEP by stressors and *d-amphetamine* might be due to release through excessive stimulation, and subsequent destruction at a rate faster than its synthesis. "Dopamine, on the other hand, is not affected by these particular stimuli. This differential depletion of catecholamines in response to various stimuli can perhaps be explained by the fact that they are distributed differently within the brain. Norepinephrine is primarily located in the hypothalamus and other brain stem areas that are believed to represent the central component of the sympathetic nervous system; dopamine is primarily located in the basal ganglia-areas associated with the extrapyramidal system."

Goldberg, M. E., Salama, A. I.: "Amphetamine toxicity and brain monoamines in three models of stress." *Toxicol. Appl. Pharmacol.* **14**: 447-456 (1969).

G66,997/69

In the mouse and rat, a significant rise in the level of brain stem 5-HT was caused by

trauma or electroshock but not by cold. "This increase was obtained in animals subjected to stress alone, or those given the highest possible nonlethal dose of *amphetamine*. These same doses did not augment the catecholamine-releasing properties of amphetamine in drum- or electric shock-stressed animals. It does not appear that stress potentiates the effects of amphetamine, as no evidence of excitation was obtained in stressed animals given amphetamine. It is postulated that amphetamine enhances the effects of stress."

Welch, B. L., Welch, A. S.: "Chronic social stimulation and tolerance to amphetamine: interacting effects of amphetamine and natural nervous stimulation upon brain amines and behavior." In: Ellingwood, E. H. Jr. and Cohen, S., *Current Concepts in Amphetamine Abuse*, pp. 107-115. Washington, D. C.: U. S. Government Printing Office, 1973. J11,597/73

Review of the literature on the enhancement of *amphetamine* toxicity by various acute stressors. Chronic stress appears to have an inverse effect as shown by experiments in mice (22 refs.).

DeFeudis, F. V., Marks, J. H.: "Studies on the time course of entry and subcellular distribution of radioactivity of (³H) *d*-amphetamine in the brains of differentially-housed mice." *Experientia* **29**: 1518-1520 (1973). H81,970/73

In mice, the accumulation of radio-marked *d-amphetamine* in synaptic particles of the brain was increased after prolonged isolation. [The authors do not specifically relate this to stress (H. S.).]

Colchicine. Leblond, C. P., Segal, G.: "Action de la cochinicine sur la surrénale et les organes lymphatiques" (Effect of colchicine on the adrenals and the lymphatic organs). *C. R. Soc. Biol. (Paris)* **128**: 995-996 (1938). A50,424/38

In rats, colchicine produces extremely severe manifestations of the alarm reaction, including adrenal enlargement and thymic-lymphatic atrophy. Adrenalectomy suppresses these actions.

Cysteamine. Flemming, K., Geierhaas, B.: "Hemmung von Cysteamin auf den Corticosterongehalt der Nebennieren von Ratten nach Stress-Einwirkung" (Inhibitory effect of cysteamine on the corticosterone content of rat adrenal glands after stress).

Experientia **28**: 965-966 (1972).

H61,481/72

In rats, cysteamine inhibits the rise in corticosterone elicited in the adrenals and plasma by various stressors.

Robert, A., Lancaster, C., Nezamis, J., Badalamenti, J.: "A new model to test antiulcer agents, cysteamine-induced duodenal ulcers." *Fed. Proc.* **33**: 310 (1974).

H84,075/74

The cysteamine-induced duodenal ulcers of rats generally respond to the same therapeutic agents as do the spontaneous duodenal ulcers of man. Hence "they represent a useful model to detect antiulcer agents, and to study the mechanism of duodenal ulcer formation."

DDD. Reznikov, A. G., Kravtsova, E. L.: "Effect of o,p'-DDD on the secretion of 11- and 17-hydroxy-corticosteroids in dogs during stress." *Patol. Fiziol. Eksp. Ter.* **14** Nos. 7-8: 38-40 (1970) (Russian).

J21,368/70

In dogs, o,p'-DDD diminished the 17-OHCS and 11-OHCS content of adrenal venous blood. They also showed decreased corticoid production when exposed to stress. o,p'-DDD disturbed the synthesis of corticosterone and cortisol to the same extent.

Hamid, J., Sayeed, A., McFarlane, H.: "The effect of 1-(o-chlorophenyl)-1-(p-chlorophenyl)-2,2-dichloroethane (o,p'-DDD) on the immune response in malnutrition." *Brit. J. exp. Pathol.* **55**: 94-100 (1974).

H86,118/74

In rats, o,p'-DDD caused loss of body weight as well as involution of the thymus, spleen and adrenals. In malnourished rats, adrenal atrophy was particularly marked and was associated with diminution of plasma corticoids and a decrease in the impairment of the immune response normally occasioned by this drug.

DDT. Wassermann, D., Wassermann, M.: "Adrenocortical zona fasciculata in rats receiving p,p'-DDT." *Environ. Physiol. Biochem.* **3**: 274-280 (1973). J11,455/73

EM studies suggest that "the inhibition of adrenal hyperplasia after surgical stress in rats receiving p,p'-DDT...as well as the lack of clear-cut morphological features of hyperactivity expected in zona fasciculata cells (as a result of an enhanced glucocorticoid clearance rate in the presence of p,p'-DDT) raise the problem of the influence of

p,p'-DDT on the chain of biochemical events of the adaptation of zona fasciculata activity to the needs."

Deoxyephedrine. (See **Methamphetamine**)

Deoxyribonucleic Acid (DNA), Ribonucleic Acid (RNA). Day, E. D., Fletcher, D. C., Naimark, G. M., Mosher, W. A.: "Sonic radiation effects on rats." *J. Aviat. Med.* **22**: 316-318 (1951). B63,927/51

In rats, exposure to an intense sound imitating that of turbojet engines caused death with typical manifestations of the G.A.S. The DNA content of the hepatic and adrenal nucleus remained unchanged.

Dibenzylamine. Ohler, E. A., Sevy, R. W.: "Inhibition of stress induced adrenal ascorbic acid depletion by morphine, dibenzylamine, and adrenal cortex extract." *Endocrinology* **59**: 347-355 (1956). C23,020/56

In rats the adrenal ascorbic acid depletion produced by sham adrenalectomy, uniadrenalectomy, EP, hydroxyamphetamine or vasopressin could be inhibited by morphine. Adrenal cortical extract blocked the response to operative stress and to catecholamines, but not to vasopressin. Dibenzylamine abolished only the reaction to catecholamines.

Diphenylhydantoin. Bliss, E. L., Migeon, C. J., Nelson, D. H., Samuels, L. T., Branch, C. H. H.: "Influence of E. C. T. and insulin coma on level of adrenocortical steroids in peripheral circulation." *Arch. Neurol. Psychiatry* **72**: 352-361 (1954). C1,997/54

In schizophrenics, electroconvulsive therapy as well as insulin coma increased the plasma level of 17-OHCS. When diphenylhydantoin was used to eliminate cyanosis, apnea and violent muscular movements, seizures still resulted in a corticoid increase but of shortened duration.

Asfeldt, V. H., Buhl, J.: "Inhibitory effect of diphenylhydantoin on the feedback control of corticotrophin release." *Acta Endocrinol. (Kbh.)* **61**: 551-560 (1969).

H15,117/69

Epileptic patients receiving diphenylhydantoin retain a normal circadian rhythm of ACTH release but respond poorly to the increase in ACTH normally produced by metyrapone or to the suppression of ACTH secretion by dexamethasone, presumably as

a result of deranged ACTH feedback controls.

DMSO. Allen, J. P., Allen, C. F.: "The effect of dimethyl sulfoxide on hypothalamic pituitary-adrenal functions in the rat." *Ann. N.Y. Acad. Sci.* **243**: 325-336 (1975).

H98,565/75

Experimental observations suggesting that dimethyl sulfoxide (DMSO) acts either directly on the hypothalamic-anterior pituitary complex to cause secretion of ACTH (presumably through the release of CRF), or that it potentiates the effect of circulating ACTH on the adrenal cortex to stimulate the secretion of corticosterone. DMSO significantly raises plasma corticosterone even in adrenalectomized or deafferented animals.

DOPA. Loon, G. R. van, Hilger, L., King, A. B., Boryczka, A. T., Ganong, W. F.: "Inhibitory effect of L-dihydroxyphenylalanine on the adrenal venous 17-hydroxycorticosteroid response to surgical stress in dogs." *Endocrinology* **88**: 1404-1414 (1971).

H39,650/71

In dogs, the adrenal venous 17-OHCS elevation after surgical stress was curtailed by L-dopa but not by NEP or intravenous dopamine. "The minimum effective dose of L-dopa that inhibited the 17-OHCS response to stress was decreased by the monoamine oxidase inhibitor, pargyline, and increased by the catecholamine synthesis inhibitor, α -methyl-p-tyrosine. These data support the hypothesis of a central adrenergic neural system which inhibits ACTH secretion in dogs" (42 refs.).

Lovinger, R. D., Connors, M. H., Kaplan, S. L., Ganong, W. F., Grumbach, M. M.: "Effect of L-dihydroxyphenylalanine (L-dopa), anesthesia and surgical stress on the secretion of growth hormone in the dog." *Endocrinology* **95**: 1317-1321 (1974).

H94,147/74

In dogs, pentobarbital anesthesia and surgical stress failed to cause significant alterations in plasma STH, whereas L-dopa elicited a pronounced rise as it did in man.

***Electrolytes, Water, Osmotic Pressure.** (See also **Osmotic Pressure under Physical Agents**) Lawzewitsch, I. von, Sarrat, R.: "Das neurosekretorische Zwischenhirn-Hypophysensystem von Vögeln nach langer osmotischer Belastung" (The neurosecretory hypothalamo-hypophyseal system of birds

after long-term osmotic stress). *Acta Anat.* (Basel) **77**: 521-539 (1970).

G84,461/70

It is concluded that "the hypothalamohypophyseal neurosecretory system of cocks under a chronic stress of a 0.3 m NaCl solution ad libitum, resulting in an exhaustion of the system, enters into a period of adaptation during which new neurosecretory material is stored by the cells of the nucleus. This adaptation could either result from the synthesizing ability of the neurosecretory cells being increased by a prolonged stress or from the decrease in hormonal demand due to functional changes in the periphery."

Levine, A. M., Higgins, J. A., Barrnett, R. J.: "Biogenesis of plasma membranes in salt glands of *salt*-stressed domestic ducklings: localization of acyltransferase activity." *J. Cell Sci.* **11**: 855-873 (1972).

Pospíšil, M.: "Electrolyte balance of the internal environment as a factor conditioning individual differences in metabolic, cellular and stress activities of the organism. Hypothesis and experimental evidence." *Agresologie* **15**: 169-177 (1974).

H97,226/74

Ethanol. (See also **Toxicomanias under Diseases of Adaptation**) Bass, A. D., Feigelson, M.: "Response of normal and malignant lymphoid tissue to non specific tissue damage." *Proc. Soc. Exp. Biol. Med.* **69**: 339-341 (1948).

B28,259/48

In mice, "ethyl alcohol is an alarming stimulus.... Fasting begun thirty hours after the initial stimulus gives an additional 'lympholytic' effect. It has been shown that stimuli which are known to produce an alarm reaction with resulting atrophy of the normal thymus and normal spleen produce a similar

type of reaction in tissue composed of malignant lymphocytes."

Mardones, J., MacLeod, L. D.: "The 'craving' for alcohol. A symposium by members of the WHO expert committees on mental health and on alcohol." *Q. J. Stud. Alcohol* **16**: 34-66 (1955). B56,097/55

Review on the effects of stress and corticoids upon alcohol craving in experimental animals and man.

Myers, R. D., Cicero, T. J.: "Effects of serotonin depletion on the volitional alcohol intake of rats during a condition of psychological stress." *Psychopharmacologia* **15**: 373-381 (1969). G70,679/69

In rats PCPA (a potent tryptophan hydroxylase inhibitor) diminishes brain 5-HT. The stress of electroshock avoidance increases ethanol intake but this preference is reduced through depletion of brain 5-HT by PCPA.

Rappaport, M.: "NAD effects on the biochemistry and psychological performance of alcoholics under ethanol stress." *Q. J. Stud. Alcohol* **30**: 570-584 (1969). J22,892/69

Allman, L. R., Taylor, H. A., Nathan, P. E.: "Group drinking during stress: effects on drinking behavior, affect, and psychopathology." *Am. J. Psychiatry* **129**: 669-678 (1972). G96,807/72

A group of three chronic alcoholics "drank most when stress and socialization periods coincided; they drank least when stress and periods of isolation occurred together."

Smith, J. F. B., Lucie, N. P.: "Alcohol—a cause of stress erythrocytosis?" *Lancet* March 24, 1973, pp. 637-638.

H67,158/73

In man, high ethanol intake causes "stress erythrocytosis" due to a reduced plasma volume.

Beard, J. D., Knott, D. H., Simpson, J. R., Sargent, W. Q.: "Cardiovascular response to hemorrhage in dogs after alcohol." *Q. J. Stud. Alcohol* **34**: 1303-1314 (1973).

J9,037/73

In dogs, mortality owing to repeated hemorrhage was considerably higher after daily gavages of an ethanol solution than following treatment with an isocaloric glucose solution. This decrease in resistance may be due to depletion of cardiac reserves caused by stress, but other stressors have not yet been examined under similar circumstances.

Ether. (See Anesthetics)

Ethionine. Marks, B. H., Vernikos-Danellis, J.: "Effect of acute stress on the pituitary gland: action of ethionine on stress-induced ACTH release." *Endocrinology* **72**: 582-587 (1963). D60,686/63

In rats, "ethionine produced a marked suppression of ACTH release following ether-laparotomy stress."

α -Ethyltryptamine, α -Methyltryptamine. Ganong, W. F., Wise, B. L., Shackleford, R., Boryczka, A. T., Zipf, B.: "Site at which α -ethyltryptamine acts to inhibit the secretion of ACTH." *Endocrinology* **76**: 526-530 (1965). F33,025/65

In dogs, α -ethyltryptamine decreased 17-OHCS output after surgical stress even if most of the CNS was removed except for "hypothalamic islands." However, direct stimulation of the ME increased 17-OHCS secretion which could not be blocked by α -ethyltryptamine. Perhaps the compound "may prevent stimulation of the CRF-secreting neurons by impulses in the incoming afferent fibers." Although α -ethyltryptamine is a MAO inhibitor, its blockade of ACTH secretion is so transient that it seems unlikely to be related to MAO inhibition. Besides, other MAO inhibitors do not share this effect.

Ganong, W. F., Boryczka, A. T., Lorenzen, L. C., Egge, A. S.: "Lack of effect of α -ethyltryptamine on ACTH secretion when blood pressure is held constant." *Proc. Soc. Exp. Biol. Med.* **124**: 558-559 (1967).

F77,622/67

In dogs, the increased ACTH secretion produced by hemorrhage is prevented by α -ethyltryptamine in doses that restore the blood pressure. Presumably, it is the latter effect of α -ethyltryptamine that causes the inhibition of ACTH secretion.

Lorenzen, L. C., Ganong, W. F.: "Effect of drugs related to α -ethyltryptamine on stress-induced ACTH secretion in the dog." *Endocrinology* **80**: 889-892 (1967).

F83,263/67

In dogs, α -methyltryptamine suppressed ACTH secretion as effectively as did α -ethyltryptamine. Corresponding tests with numerous indole derivatives, MAO inhibitors, antidepressants and pressor amines revealed that the ACTH-blocking activity of α -methyltryptamine is correlated only with its pressor action since it is shared by vasopressors. The

effect is unrelated to any other chemical or pharmacologic property of the drugs used for comparison.

Formaldehyde. Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* **17**: 234-248 (1936). 36,032/36

First detailed description of the "alarm reaction" characterized by adrenocortical enlargement with acute loss of lipids, thymic-lymphatic atrophy and decreased body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for forty-eight hours or more, large doses of atropine, morphine, formaldehyde or EP). Adrenalectomy and to a lesser extent hypophysectomy prevent the thymus involution. "The changes caused by a drug when it is given for the first time will subside later in spite of the continued administration of this drug," but greatly shorten survival. Perhaps the adrenal enlargement, loss of body weight and other manifestations of the alarm reaction enable the organism "to meet critical situations more efficiently."

Weisz, P., Kádas, T., Köves, P., Ritter, L.: "Einwirkung der chronischen Formalinbehandlung auf die Corticosteronausscheidung der Nebennieren bei weissen Ratten" (Effect of chronic formalin treatment on the corticosterone secretion of the adrenals in white rats). *Endocrinologie* **38**: 80-85 (1959).

C74,539/59

In rats, chronic treatment with formaldehyde caused enlargement of the adrenals, but a pronounced increase in corticosterone excretion was not observed. Apparently, the functional and morphologic stimulation of the adrenal cortex may depend upon independent factors.

Ahrén, C.: "Effects of diencephalic lesions on acute and chronic stress responses in male rabbits." *Acta Endocrinol. (Kbh.)* **41** Suppl. 69: 1-92 (1962). D38,126/62

Monograph on the effect of variously placed diencephalic lesions upon the stress response of rabbits given formalin subcutaneously. "The results indicate that the lymphopenic response was completely blocked by small, circumscribed lesions in the region of the dorsomedial and ventromedial nuclei as well as by lesions in the posterior border of the mammillary bodies and the region dorso-

caudal thereto, whilst it remained unaffected by lesions in the premammillary area or in the anterior half or all the mammillary bodies. Lesions in the anterior preoptic area and posterior orbitofrontal cortex, in the ventro-caudal septum or in the anterior hypothalamic area dorsocaudal to the optic chiasm were associated with partial inhibition, and occasionally even with total blockage, of the lymphopenic response." The findings do not permit conclusions concerning any particular region which would represent a "center" of such stress responses in the limbic structures or mesencephalon.

Glucose. (See also other carbohydrates) Selye, H., MacLean, A.: "Prevention of gastric ulcer formation during the alarm reaction." *Am. J. Dig. Dis.* **11**: 319-322 (1944).

A75,010/44

In rats, the gastric ulcers produced by transection of the spinal cord at the height of the seventh cervical vertebra may be prevented by the prophylactic administration of various food substances, aluminum hydroxide gel and especially by comparatively small doses of dextrose given orally or intravenously. Even in doses insufficient to raise the glucose content of the blood above the normal level, dextrose inhibited gastric ulcer formation for the duration of the experiment. Its prophylactic effect is nonspecific in the sense that it prevents the formation of gastric ulcers in animals exposed to a wide variety of stressors such as formaldehyde injections, exposure to cold or spinal cord transection.

Pyant, R. L. Jr., Mullane, J. F.: "Starvation, glucose ingestion and stress ulcer formation in the rat." *Clin. Res.* **20**: 872 (1972).

H62,440/72

Stress ulcer production by restraint is facilitated in rats by four but not by two days of previous starvation. Oral administration of glucose has a protective effect.

Rayfield, E. J., George, D. T., Beisel, W. R.: "Altered growth hormone homeostasis during acute bacterial sepsis in the rhesus monkey." *J. Clin. Endocrinol. Metab.* **38**: 746-754 (1974). H86,214/74

Studies on monkeys demonstrate an exaggerated STH response following an intravenous glucose load during the stress of acute infection, and suggest that this reaction may be suppressed with chlorpromazine.

Halothane. (See Anesthetics)

Histamine. (See Hormones and Hormone-like Substances)

6-Hydroxydopamine. Delft, A. M. L. van, Nyakas, C., Kaplanski, J., Tilders, F. J. H.: "The effect of 6-hydroxydopamine administration to neonatal rats on some endocrine and behavioral parameters." *Arch. Int. Pharmacodyn. Ther.* **206:** 403-404 (1973). H82,629/73

Depletion of catecholamines in the rat brain by 6-hydroxydopamine caused severe anorexia, impairment of growth, and delayed vaginal opening, but curiously, the stressor activity of the pituitary-adrenal system did not appear to be significantly affected. "Adrenal weights were normal when expressed per 100 g body weight. Diurnal peak and trough activities of adrenocortical activity as determined by measuring both plasma corticosterone levels and corticoid production of excised adrenal tissue in vitro were comparable to the activities found in control rats. Also the response of the pituitary-adrenal system when animals were exposed to strange environment or ether stress was completely within the normal range. These findings raise serious doubts with regard to the theory of the existence of a noradrenergic inhibitory system acting on pituitary-adrenal regulatory processes in the brain."

Leduc, J.: "Effet de la sympathectomie chez le rat exposé au froid" (Effect of sympathectomy on rats exposed to cold). *Ann. ACFAS* **40:** 128 (1973). H87,897/73

6-Hydroxydopamine, which causes a "chemical sympathectomy," greatly diminished resistance to cold. There was a marked rise in urinary EP but not NEP. Apparently, the adrenal medulla can largely compensate for the loss of sympathetic nerve activity.

Insecticides. (See individual agents, e.g., DDT) Murphy, S. D.: "Some relationships between effects of insecticides and other stress conditions." *Ann. N.Y. Acad. Sci.* **160:** 366-377 (1969). G78,902/69

Isethionate. Bennett, J., Dave, C.: "Effect of intravenous infusion of isethionate on rats." *Proc. Soc. Exp. Biol. Med.* **146:** 170-175 (1974). H87,184/74

Isethionate, a metabolite of taurine found in various tissues, caused only very mild stress manifestations when chronically infused into rats. It is probable that even these were largely the result of immobilization and

the infusion procedure rather than of the drug.

Ketamine. (See Anesthetics)

***MAO inhibitors.** (See also α -ethyltryptamine) Ostow, M.: "Orthostatic hypotension and psychic energizers: a clinical note." *Psychosomatics* **7:** 224-225 (1966).

F68,735/66

In patients treated with MAO inhibitors, both stressors and glucocorticoids combat the resulting orthostatic hypotension. Endogenous glucocorticoid liberation may have a therapeutic effect on this condition.

Vermesh, I., Ryzhenkov, V. E.: "Functional condition of the hypophysis-adrenal system in rats with deafferentated hypothalamus; the action of dexamethasone and nialamide." *Probl. Endokrinol.* **20** No. 3: 67-70 (1974) (Russian). H92,315/74

In rats with a completely deafferented medio-basal hypothalamus, the basal plasma corticosterone level rose but could be curtailed by dexamethasone or nialamide. "At the same time suppression of corticosterone secretion in stress by nialamide was stronger in comparison with dexamethasone. Nialamide potentiated the depressive action of dexamethasone on the basal corticosterone secretion, but not under stress [restraint]."

Marijuana. (See Cannabis)

Meprobamate. (See also Tranquilizers) Mäkelä, S., Näätänen, E., Rinne, U. K.: "The response of the adrenal cortex to psychic stress after meprobamate treatment." *Acta Endocrinol.* **32:** 1-7 (1959).

C75,051/59

In rats "meprobamate is able under acute experimental conditions to inhibit the ascorbic acid depletion caused by psychic stress although in the meprobamate plus psychic stress group the adrenal ascorbic acid quantity was highly significantly less than in the controls." After chronic treatment the effect of meprobamate gradually disappears. Curiously, the drug alone stimulates the adrenal cortex in intact and in unilaterally adrenalectomized rats.

Myers, R. D.: "Effects of meprobamate on alcohol preference and on the stress of response extinction in rats." *Psychol. Rep.* **8:** 385-392 (1961). J12,455/61

Frankenhaeuser, M., Kareby, S.: "Effect of meprobamate on catecholamine excretion

during mental stress." *Percept. Mot. Skills* **15**: 571-577 (1962). E30,225/62

In students psychogenic stress (problem solving, and to a lesser extent even anticipation of such tests) augmented EP and NEP excretion. After simultaneous administration of meprobamate, EP output increased but NEP decreased during stress. Thus, "meprobamate in moderate doses counteracted the increase in the catecholamine response of normal individuals subjected to mental stress in a laboratory situation."

Methadone. Farmer, R. W., Harrington, C. A., Fabre, L. F. Jr.: "Inhibition of steroid biosynthesis in isolated rat adrenal cells by methadone." *Fed. Proc.* **33**: 288 (1974).

H84,044/74

Methamphetamine. (See also CNS Stimulants). Frankenhaeuser, M., Post, B.: "Catecholamine excretion during mental work as modified by centrally acting drugs." *Acta Physiol. Scand.* **55**: 74-81 (1962).

D35,589/62

In medical students the stress of various "intellectual tests" increased urinary EP excretion, and this change could be suppressed by methamphetamine and pentobarbital. It appears that "urinary excretion of adrenaline provides a sensitive measure of reactions to mental stress, and that centrally acting drugs may influence adrenaline excretion during mental work."

Yamashita, I., Morojo, T., Yamazaki, K., Kato, H., Sakashita, A., Onodera, I., Ito, K., Okada, F., Saito, Y., Tamakoshi, M., Suwa, N.: "Neuroendocrinological studies in mental disorders and psychotropic drugs. I. On the circadian rhythm of the plasma adrenocortical hormone in mental patients and methamphetamine- and chlorpromazine-treated animals." *Folia Psychiatr. Neurol. Jap.* **23**: 143-158 (1969). G72,651/69

The circadian plasma corticosteroid rhythm was deranged in rats treated with methamphetamine or chlorpromazine.

α -Methyl-p-tyrosine. (See α -MT)

α -Methyltryptamine. (See α -Ethyltryptamine)

Metrazol. Palfai, T., Kurtz, P., Gutman, A.: "Effect of metrazol on brain norepinephrine: a possible factor in amnesia produced by the drug." *Pharmacol. Biochem. Behav.* **2**: 261-262 (1974). J12,891/74

In mice, metrazol-induced seizures diminish brain NEP.

Metyrapone. Kaplan, N. M.: "Assessment of pituitary ACTH secretory capacity with Metopirone: II. Comparison with other tests." *J. Clin. Endocrinol. Metab.* **23**: 953-960 (1963). E27,529/63

Observations in man "confirm the impression that the Metopirone test is the most sensitive measure now available for assessing pituitary ACTH secretory capacity. Discrepancies between the Metopirone and insulin tolerance tests were noted, indicating that the Metopirone test should be considered a measure of only one aspect of pituitary ACTH secretory capacity, and not necessarily a measure of total reserve."

French, F. S., Macfie, J. A., Williams, T. F., Wyk, J. J. van: "Cushing's syndrome with a paradoxical response to dexamethasone." *Am. J. Med.* **47**: 619-624 (1969).

G70,061/69

In a patient with Cushing's syndrome (due to a basophil hypophyseal adenoma) dexamethasone increased urinary 17-OHCS and 17-KS excretion as well as plasma ACTH activity. Metyrapone caused the expected initial rise in urinary 17-KS (due to augmentation of tetrahydro-11-deoxycortisol), but a much larger increase in adrenal corticoid excretion occurred on the second and third days and was associated with the reappearance of urinary cortisol metabolites.

Asfeldt, V. H., Buhl, J.: "Inhibitory effect of diphenylhydantoin on the feedback control of corticotrophin release." *Acta Endocrinol. (Kbh.)* **61**: 551-560 (1969). H15,117/69

Epileptic patients receiving diphenylhydantoin retain a normal circadian rhythm of ACTH release but respond poorly to the increase in ACTH normally produced by metyrapone or to the suppression of ACTH secretion by dexamethasone, presumably as a result of deranged ACTH feedback controls.

Jensen, H. K., Blichert-Toft, M.: "Investigation of pituitary-adrenocortical function in the elderly during standardized operations and postoperative intravenous metyrapone test assessed by plasma cortisol, plasma compound S and eosinophil cell determinations." *Acta Endocrinol. (Kbh.)* **67**: 495-507 (1971). H42,510/71

During the postoperative stage, elderly patients show a significantly stronger response to intravenous metyrapone than do young persons.

Morphine. (See also **Anesthetics and Analgesics**) Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* **17**: 234-248 (1936). *C36,032/36*

First detailed description of the "alarm reaction" characterized by adrenocortical enlargement with acute loss of lipids, thymicolympathic atrophy and decreased body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for forty-eight hours or more, large doses of atropine, morphine, formaldehyde or EP). Adrenalectomy and to a lesser extent hypophysectomy prevent the thymus involution. "The changes caused by a drug when it is given for the first time will subside later in spite of the continued administration of this drug," but will greatly shorten survival. Perhaps the adrenal enlargement, loss of body weight and other manifestations of the alarm reaction enable the organism "to meet critical situations more efficiently."

Briggs, F. N., Munson, P. L.: "Studies on the mechanism of stimulation of ACTH secretion with the aid of morphine as a blocking agent." *Endocrinology* **57**: 205-219 (1955). *C7,791/55*

In rats, morphine blocks the ACTH secretion induced by various stressors (histamine, EP, vasopressin, laparotomy) or unilateral adrenalectomy, whereas these stimuli were effective in anesthetized controls. The effect of exogenous ACTH was not blocked by morphine, showing that the drug fails to interfere directly with the response of the adrenal cortex.

Ohler, E. A., Sevy, R. W.: "Inhibition of stress induced adrenal ascorbic acid depletion by morphine, dibenzylidine, and adrenal cortex extract." *Endocrinology* **59**: 347-355 (1956). *C23,020/56*

In rats, the adrenal ascorbic acid depletion produced by sham adrenalectomy, unilateradrenalectomy, EP, hydroxyamphetamine or vasopressin could be inhibited by morphine. Adrenal cortical extract blocked the response to operative stress and to catecholamines but not to vasopressin. Dibenzylidine blocked only the reaction to catecholamines.

Epstein, S., Burdette, H., Munson, P. L.: "Effect of nalorphine on inhibition of ACTH release by morphine in the rat." *Fed. Proc.* **16**: 294 (1957). *C33,192/57*

Leeman, S. E., Munson, P. L.: "In vivo

system for detection of the neural hormone responsible for ACTH secretion in stress." *Fed. Proc.* **17**: 387 (1958). *C51,861/58*

In rats, blockade of ACTH secretion by morphine is used as a basis for the bioassay of CRF.

Tanabe, T., Cafruny, E. J.: "Adrenal hypertrophy in rats treated chronically with morphine." *J. Pharmacol. Exp. Ther.* **122**: 148-153 (1958). *C48,625/58*

In rats, chronic morphine treatment caused adrenal enlargement that was prevented by hypophysectomy, although "the ability of hypophysectomized rats to tolerate large doses of morphine and morphine-withdrawal stresses did not seem to be impaired."

Wied, D. de, Bouman, P. R., Smelik, P. G.: "The effect of a lipide extract from the posterior hypothalamus and of Pitressin on the release of ACTH from the pituitary gland." *Endocrinology* **62**: 605-613 (1958). *C52,310/58*

In rats, various lipid extracts of bovine hypothalamus and vasopressin stimulated ACTH secretion. Blockade with morphine or cortisol inhibited the effect of the lipid extracts, but only morphine prevented ACTH discharge by vasopressin, which was obtained even after destruction of the ME. "It is concluded that the lipide extract requires the intactness of hypothalamic structures for its action, and that Pitressin contains the specific neurotransmitter."

Doepfner, W., Stürmer, E., Berde, B.: "On the corticotrophin-releasing activity of synthetic neurohypophysial hormones and some related peptides." *Endocrinology* **72**: 897-902 (1963). *D67,095/63*

In rats, the ACTH-releasing activity of vasopressin and oxytocin preparations was tested after blockade of ACTH release by morphine. "The pressor and the CRF activities of peptides related to the neurohypophysial hormones need not be strictly correlated."

Munson, P. L.: "Pharmacology of neuroendocrine blocking agents." In: Nalbandov, A. V., *Advances in Neuroendocrinology*, pp. 427-444. Urbana, Ill.: University of Illinois Press, 1963. *J12,674/63*

A review of the literature shows that chlorpromazine, reserpine and morphine may inhibit ACTH secretion, but only the action of morphine is striking and consistent. Yet, in extremely high doses morphine stimulates adrenocortical activity, and in fact was one

of the first stressors described in the original publication on the alarm reaction (117 refs.).

Stevens, M. W., Domer, F. R.: "Alterations in morphine-induced analgesia in mice exposed to pain, light or sound." *Arch. Int. Pharmacodyn. Ther.* **206**: 66-75 (1973).

H82,603/73

In mice, pain stimuli significantly increased both the rate of onset and the intensity of morphine analgesia. This was not so in animals exposed to photic or auditory stimuli.

Brown, W. A., Krieger, D. T., Woert, M. H. van, Ambani, L. M.: "Dissociation of growth hormone and cortisol release following apomorphine." *J. Clin. Endocrinol. Metab.* **38**: 1127-1130 (1974). H87,291/74

In man, apomorphine-induced STH release is probably not mediated through systemic stress but through a specific effect on dopamine receptor sites in the ME, since dopaminergic stimulation is not associated with cortisol release.

α -MT. Scapagnini, U., Loon, G. R. van, Moberg, G. P., Ganong, W. F.: "Effect of α -methyl-p-tyrosine on the circadian variation of plasma corticosterone in rats." *Eur. J. Pharmacol.* **11**: 266-268 (1970).

H27,438/70

α -MT increased plasma corticosterone in most rats at all times of the day. Hypothalamic catecholamine content fell in rats in which α -MT increased plasma corticosterone but not in others. "The data are consistent with the hypothesis that an adrenergic neural system inhibits ACTH secretion."

Halawani, M. E. el, Waibel, P. E., Appel, J. R., Good, A. L.: "Effects of temperature stress on catecholamines and corticosterone of male turkeys." *Am. J. Physiol.* **224**: 384-388 (1973). H65,841/73

In male turkeys, neither heat nor stress had any pronounced effect upon adrenal, brain or heart catecholamine concentrations; however, plasma corticosterone levels rose. When α -MT (an inhibitor of catecholamine synthesis) was given prior to stress exposure, catecholamine concentrations fell markedly unless the birds had been previously adapted to hot or cold environments. "These findings indicate that an increased rate of catecholamine and corticosterone release seems to be required during the initial response to temperature stress, and may be associated with the adaptive changes leading to temperature acclimation" (20 refs.).

*Mustards. Karnofsky, D. A., Graef, I., Smith, H. W.: "Studies on the mechanism of action of the nitrogen and sulfur mustards in vivo." *Am. J. Pathol.* **24**: 275-291 (1948). J8,918/48

Observations on rats showed that the systemic intoxication produced by mustard compounds "resembles in many respects a pattern of organic changes that has been termed by Selye the 'alarm reaction.' "

*Narcotics and Other Psychotropic Drugs. (See Anesthetics and CNS Stimulants) Franzén, G.: "Serum cortisol in chronic schizophrenia. Changes in the diurnal rhythm and psychiatric mental status on withdrawal of drugs." *Psychiatr. Clin. (Basel)* **4**: 237-246 (1971). G86,703/71

Farmer, R. W., Harrington, C. A., Fabre, L. F. Jr.: "Inhibition of steroid biosynthesis in isolated rat adrenal cells by methadone." *Fed. Proc.* **33**: 288 (1974). H84,044/74

Neuroleptics. (See CNS Stimulants and Methamphetamine)

Nialamide. Vermes, I., Telegdy, G.: "Adrenal function following drug-induced alterations of the hypothalamic serotonin content." *Acta Physiol. Acad. Sci. Hung.* **43**: 105-114 (1973). J12,928/73

In rats PCPA lowered the hypothalamic 5-HT level and facilitated stimulation of corticosterone secretion by "ether stress." Nialamide increased hypothalamic 5-HT but blocked the adrenal response to stress. Reserpine lowered hypothalamic 5-HT and augmented basal corticoid secretion; however, after "ether stress" there was no response either in hypothalamic 5-HT content or adrenal function. In any event the results suggest that "the changes induced in the stress mechanism by different drugs are related to their action on the hypothalamic serotonin level. Its increase inhibits, while its decrease facilitates, the stress-induced activation of pituitary-adrenal function."

Vermesh, I., Ryzhenkov, V. E.: "Functional condition of the hypophysis-adrenal system in rats with deafferentated hypothalamus; the action of dexamethasone and nialamide." *Probl. Endokrinol.* **20** No. 3: 67-70 (1974) (Russian). H92,315/74

In rats with a completely deafferented MBH, the basal plasma corticosterone level rose; this elevation could be inhibited by dexamethasone or nialamide. "At the same

time suppression of corticosterone secretion in stress [restraint] by nialamide was stronger in comparison with dexamethasone. Nialamide potentiated the depressive action of dexamethasone on the basal corticosterone secretion, but not under stress."

Nicotine. Schechter, M. D.: "Effect of nicotine on response to frustrative non-reward in the rat." *Eur. J. Pharmacol.* **29:** 312-315 (1974). H96,851/74

"Rats were subjected to frustrative non-reward in the Amsel double runway after administration of nicotine and saline. Results revealed that nicotine decreases the magnitude of the frustrative effect when compared to saline."

Nicotinic Acid. Carlson, L. A., Levi, L., Orö, L.: "Plasma lipids and urinary excretion of catecholamines in man during experimentally induced emotional stress, and their modification by nicotinic acid." *J. Clin. Invest.* **47:** 1795-1805 (1968). H1,440/68

In male volunteers, emotional stressors (dazzling light, standardized criticism, sorting steel balls of different sizes) caused a rise in plasma FFA and triglycerides as well as increased catecholamine excretion. Concurrent treatment with nicotinic acid prevented the elevation of FFA and triglycerides, but not the stressor-induced increase in catecholamine elimination, or the associated rise in heart rate and blood pressure.

Lindenbaum, E. S., Diamond, B., Yaryura-Tobías, J. A.: "Nicotinic acid and restraint induced ulcers." *Acta Physiol. Lat. Am.* **23:** 288-292 (1973). J9,059/73

In rats, the gastric ulcers produced by restraint with food and water deprivation are more effectively inhibited by nicotinic acid than by chlorpromazine.

Nitrous Oxide. (See also **Anesthetics and Analgesics**) Steinberg, H.: "Effects of nitrous oxide on reactions to stress." *Bull. Br. Psychol. Soc.* **24:** 12 (1954). J13,306/54

In man inhalation of small amounts of nitrous oxide (sufficient to cause euphoria) reduced the stress elicited by being asked to solve insoluble problems. [The brief abstract gives no details about how this was measured (H.S.).]

Russell, R. W., Steinberg, H.: "Effects of nitrous oxide on reactions to 'stress.'" *Q. J. Exp. Psychol.* **7:** 67-73 (1955).

D81,503/55

"The present investigation using insoluble and soluble problems has demonstrated that both nitrous oxide and exposure to stress impair learning; but that, when subjects are exposed to stress while under the influence of the drug, the effects of the stress on subsequent learning are abolished."

Oxprenolol. (See **Antiadrenergics**)

PCPA. Myers, R. D., Cicero, T. J.: "Effects of serotonin depletion on the volitional alcohol intake of rats during a condition of psychological stress." *Psychopharmacologia* **15:** 373-381 (1969). G70,679/69

In rats PCPA (a potent tryptophan hydroxylase inhibitor) diminishes brain 5-HT. The stress of electroshock avoidance increases ethanol intake but this preference is reduced by depletion of brain 5-HT by PCPA.

Scapagnini, U., Moberg, G. P., Loon, G. R. van, Groot, J. de, Ganong, W. F.: "Relation of brain 5-hydroxytryptamine content to the diurnal variation in plasma corticosterone in the rat." *Neuroendocrinology* **7:** 90-96 (1971). H36,747/71

The 5-HT content of the hippocampus and amygdala exhibits a circadian rhythm in rats which roughly parallels that of plasma corticosterone. PCPA, which blocks 5-HT synthesis, increases the a.m. and decreases the p.m. plasma corticosterone levels so that circadian variations are largely eliminated. "The results suggest that 'serotonergic' neurons play a role in the diurnal fluctuation in pituitary-adrenal function."

Vermes, I., Telegdy, G.: "Adrenal function following drug-induced alterations of the hypothalamic serotonin content." *Acta Physiol. Acad. Sci. Hung.* **43:** 105-114 (1973). J12,928/73

In rats PCPA lowered the hypothalamic 5-HT level and facilitated stimulation of corticosterone secretion by "ether stress." Nialamide increased hypothalamic 5-HT but blocked the adrenal response to stress. Reserpine lowered hypothalamic 5-HT and augmented basal corticoid secretion; however, after "ether stress" there was no response either in hypothalamic 5-HT content or adrenal function. In any event the results suggest that "the changes induced in the stress mechanism by different drugs are related to their action on the hypothalamic serotonin level. Its increase inhibits, while its

decrease facilitates, the stress-induced activation of pituitary-adrenal function."

Hill, S. Y., Goldstein, R.: "Effect of p-chlorophenylalanine and stress on alcohol consumption by rats." *Q. J. Stud. Alcohol* **35**: 34-41 (1974). J13,259/74

PCPA caused a marked depletion of brain 5-HT and reduced volitional alcohol intake in the rat. These effects could be inhibited under certain conditions by stressors (for example, electroshock). Indeed, there is no evidence that PCPA ordinarily induces avoidance of alcohol (20 refs.).

Pimozide. Mierlo, P. J. van: "Open pilot trial of pimozide in patients suffering from psychic stress." *Arzneim. Forsch.* **22**: 2147-2148 (1972). H64,912/72

Polychlorinated Biphenyls. Wassermann, D., Wassermann, M., Cucos, S., Djavaherian, M.: "Function of adrenal gland-zona fasciculata in rats receiving polychlorinated biphenyls." *Environ. Res.* **6**: 334-338 (1973). J6,552/73

In rats given toxic polychlorinated biphenyls, plasma corticosterone levels rose sharply and characteristic structural changes developed in the fasciculata of the adrenal. "The results are interpreted as evidence of the need for a higher level of glucosteroids in defense against the stressor character of PCBs-1221 and perhaps also of the need for catatotoxic activity of glucosteroids."

Propranolol. (See **Antiadrenergics**)

Psychotropic Drugs. (See also individual psychotropic and psychotomimetic agents) Meltzer, H. Y.: "Muscle toxicity produced by phencyclidine and restraint stress." *Res. Commun. Chem. Path. Pharmacol.* **3**: 369-382 (1972). H52,159/72

In rats stressed by restraint, the toxicity of *phencyclidine* (a potent psychotomimetic agent) is greatly enhanced.

Glass, G. S.: "Psychedelic drugs, stress, and the ego. The differential diagnosis of psychosis associated with *psychotomimetic* drug use." *J. Nerv. Ment. Dis.* **156**: 232-241 (1973). J2,562/73

Wray, S. R.: "Interaction of stress and psychotomimetic drug-action: possible implication for psychosis." *Psychopharmacologia* **30**: 263-268 (1973). J4,950/73

From experiments on rats concerning the effect of avoidance responses to electroshock

upon the psychotomimetic drug *cyclazocine*, it is concluded that "environmental stress can play a crucial role in the genesis and underlying mechanism of schizophrenia."

Reserpine. (See also **Tranquilizers**) Mason, J. W., Brady, J. V.: "Plasma 17-hydroxycorticosteroid changes related to reserpine effects on emotional behavior." *Science* **124**: 983-984 (1956).

C25,425/56

In rhesus monkeys, moderate doses of reserpine inhibited not only experimentally induced anxiety and fear responses, but also the associated increase in plasma 17-OHCS levels. This fact is all the more interesting since, in themselves, comparable doses of reserpine produced a transient increase in 17-OHCS.

Wells, H., Briggs, F. N., Munson, P. L.: "The inhibitory effect of reserpine on ACTH secretion in response to stressful stimuli." *Endocrinology* **59**: 571-579 (1956).

G21,910/56

Miline, R., Stern, P.: "Effect of reserpine on the stressogenic reactivity of habenular-pineal complex." *Anat. Rec.* **136**: 243-244 (1958).

C95,318/58

In hares, fear caused regressive changes in the internal nuclear habenular ganglion which could be prevented by reserpine. Allegedly, the results "show that the habenular-pineal complex has an important role in the neuroendocrinology of the general adaptation syndrome."

Knigge, K. M., Penrod, C. H., Schindler, W. J.: "In vitro and in vivo adrenal corticosteroid secretion following stress." *Am. J. Physiol.* **196**: 579-582 (1959).

C65,769/59

In rats, scalding or restraint produced an initial biphasic response in ACTH and corticosterone secretion. The decrease was not due to adrenal exhaustion, for it occurred at the time when the pituitary contained approximately twice the normal amount of ACTH. "The low level of hormone secretion was replaced by very high levels by treatment of the stressed rat with reserpine or by placement of hypothalamic lesions. At a variable time after stress, corresponding to time of least corticosteroid secretion, there appears to exist an inability of the pituitary to release ACTH, which may be due to cessation of the initial hypothalamic stimulation or to a neural mechanism which temporarily

suppresses or inhibits the secretion of endogenous ACTH."

Blackman, J. G., Campion, D. S., Fastier, F. N.: "Mechanism of action of reserpine in producing gastric haemorrhage and erosion in the mouse." *Br. J. Pharmacol.* **14**: 112-116 (1959). C68,958/59

Gastric hemorrhage and erosion are produced in mice by reserpine through a mechanism involving liberation of 5-HT.

Kitay, J. I., Holub, D. A., Jailer, J. W.: "'Inhibition' of pituitary ACTH release after administration of reserpine or epinephrine." *Endocrinology* **65**: 548-554 (1959).

C74,892/59

In rats, single injections of EP or reserpine produced an ACTH discharge, yet "the acute release of ACTH in response to the stress of ether anesthesia was found to be diminished or absent after a single injection of epinephrine or after multiple injections of either reserpine or epinephrine. These data are consistent with the hypothesis that the amount of pituitary ACTH available for immediate release in response to acute stress is reduced after administration of reserpine or epinephrine, whereas chronic hypersecretion of ACTH remains unimpaired."

Maickel, R. P., Westermann, E. O., Brodie, B. B.: "Effects of reserpine and cold-exposure on pituitary-adrenocortical function in rats." *J. Pharmacol. Exp. Ther.* **134**: 167-175 (1961). D48,441/61

Reserpine and those reserpine derivatives which decrease brain NEP and 5-HT produced sedation and ACTH hypersecretion in rats. Large doses of reserpine or prolonged cold exposure decreased the ACTH content of the pituitary sufficiently to prevent a detectable discharge in response to other stressors.

Damrau, F.: "Peptic ulcers induced in white rats by reserpine and stress. The protective action of roterized bismuth subnitrate." *Am. J. Gastroenterol.* **35**: 612-618 (1961). D92,441/61

Efron, D. H.: "Reserpine toxicity and 'nonspecific stress.'" *Life Sci.* **1**: 561-564 (1962). D59,758/62

"The increased toxicity of reserpine in adrenalectomized rats is related to the absolute lack of certain adrenal steroids, which in some way may condition the nervous system to the effects of the drug, rather than to the inability of the pituitary-adrenal system to

respond to so-called 'nonspecific stress' caused by the drug."

Taylor, R. E. Jr., Fregly, M. J.: "Effect of reserpine on body temperature regulation of the rat." *J. Pharmacol. Exp. Ther.* **138**: 200-207 (1962). D41,319/62

In rats, intraperitoneal reserpine diminishes body temperature much more at low than at high environmental temperatures. It acts by decreasing heat production rather than by increasing heat loss. Restraint augmented the reserpine-induced decrease in body temperature.

Dasgupta, S. R., Mazumder, R. C.: "A study of the effect of reserpine (Serpasil) on lymphocytopenia of stress in rabbits." *Arch. Int. Pharmacodyn. Ther.* **138**: 120-124 (1962). D30,286/62

In rabbits, "reserpine not only failed to prevent lymphocytopenia of stress, but appeared to enhance the lymphocytopenia, indicating a stimulant type action of reserpine on the hypothalamus."

Girod, C.: "Influence de la réserpine sur l'axe hypophysocorticosurrénalien, chez le singe *Macacus sylvanus L.*" (The influence of reserpine on the pituitary-adrenal cortex axis in the *Macacus sylvanus L.* monkey). *C.R. Acad. Sci. (Paris)* **256**: 1600-1602 (1963). D62,899/63

In the monkey *Macacus sylvanus L.*, reserpine causes adrenal hyperactivity with pituitary changes suggestive of increased ACTH secretion.

Halkerston, I. D. K., Feinstein, M., Hechter, O.: "Increased responsiveness of adrenals from reserpine-treated or stressed rats to steroidogenic activity of ACTH." *Proc. Soc. Exp. Biol. Med.* **115**: 292-295 (1964). F2,446/64

Feldman, S., Conforti, N., Davidson, J. M.: "Adrenocortical responses in rats with corticosteroid and reserpine implants." *Neuroendocrinology* **1**: 228-239 (1966).

F68,591/66

Dexamethasone or cortisol pellets implanted into the ME of rats inhibited compensatory hypertrophy of the remaining adrenal following unilateral adrenalectomy. Dexamethasone implants into the pituitary itself exerted only a slight inhibition. Similar implants of reserpine or subcutaneous injections of the substance could not be shown "to be involved in the negative feedback regulation of ACTH secretion by corticosteroids."

Smelik, P. G.: "ACTH secretion after depletion of hypothalamic monoamines by reserpine implants." *Neuroendocrinology* **2**: 247-254 (1967). F90,175/67

Implantation of reserpine into the rat hypothalamus depleted the regional 5-HT and catecholamine content. Nevertheless, after subsequent systemic administration of reserpine, chlorpromazine and vasopressin, as well as emotional and traumatic stress, the pituitary-adrenal response was not modified by the depletion of hypothalamic monoamines. Presumably, "under these experimental conditions there is no indication that monoamines present in the hypothalamus are involved in the control of pituitary ACTH secretion."

Doteuchi, M.: "Studies on the experimental gastrointestinal ulcers produced by reserpine and stress. I. Relationship between production of ulcers and changes in tissue monoamines." *Jap. J. Pharmacol.* **17**: 638-647 (1967). F96,238/67

Kobayashi, T., Kobayashi, T., Yamamoto, K., Kaibara, M., Ajika, K.: "Electron microscopic observation on the hypothalamo-hypophyseal system in the rat. III. Effect of reserpine treatment on the axonal inclusions in the median eminence." *Endocrinol. Jap.* **15**: 321-335 (1968). H4,331/68

In reserpine-treated rats, EM studies of the ME revealed an increase in electron-dense large granules (thought to be carriers of neurohypophyseal hormones) and a decrease in small granules (presumably carriers of catecholamines).

Doteuchi, M.: "Studies on the experimental gastrointestinal ulcers produced by reserpine and stress. II. Ulcerogenic activities of reserpine and its analogues." *Jap. J. Pharmacol.* **18**: 130-138 (1968). J16,601/68

Observations on cats suggest that a decrease in peripheral and central monoamines is involved in gastric ulcer formation caused by reserpine and its analogues in combination with electroshock.

Doteuchi, M.: "Studies on the experimental gastrointestinal ulcers produced by reserpine and stress. III. Effects of monoamines and their precursors." *Jap. J. Pharmacol.* **18**: 175-184 (1968). J16,602/68

In cats, gastric ulcer formation by reserpine plus electroshock could be inhibited by 5-hydroxytryptophane, dopa and atropine. These and other observations suggested that

a decrease in monoamine content of the CNS was involved in the development of stress ulcers.

Carr, L. A., Moore, K. E.: "Effects of reserpine and α -methyltyrosine on brain catecholamines and the pituitary-adrenal response to stress." *Neuroendocrinology* **3**: 285-302 (1968). H3,332/68

The brain content of NEP and dopamine was markedly reduced in rats given reserpine (which depletes catecholamine stores) or α -MT (which blocks catecholamine synthesis). Plasma corticosterone was essentially unchanged in the rats at rest as well as after treatment with stressors (ether, histamine, formalin, restraint, changes in environment). "The results suggest that brain catecholamines do not play an essential role in stress-induced activation of the pituitary-adrenal system."

Boulu, R., Schwartz, J. C.: "Ulcères gastriques médicamenteux et température environnante" (Drug-induced gastric ulcers and environmental temperature). *C. R. Acad. Sci. (Paris)* **268**: 2507-2510 (1969).

G67,252/69

The production of gastric ulcers in rats by reserpine, phenylbutazone and desoxy-2-glucose is much higher at 20°C than at 37°C.

Blaszkowski, T. P., DeFeo, J. J., Guarino, A. M.: "Central vs. peripheral catecholamines in rats during adaptation to chronic restraint stress." *Pharmacology* **4**: 321-333 (1970). H36,516/70

Reserpine pretreatment increases the mortality of rats exposed to the stress of restraint, presumably because of its central rather than peripheral NEP-depleting action.

Purchas, R. W.: "The response of circulating cortisol levels in sheep to various stresses and to reserpine administration." *Aust. J. Biol. Sci.* **26**: 477-489 (1973). J3,638/73

Vermes, I., Telegdy, G.: "Adrenal function following drug-induced alterations of the hypothalamic serotonin content." *Acta Physiol. Acad. Sci. Hung.* **43**: 105-114 (1973).

J12,928/73

In rats, PCPA lowered the hypothalamic 5-HT level and facilitated stimulation of corticosterone secretion by "ether stress." Nialamide increased hypothalamic 5-HT but blocked the adrenal response to stress. Reserpine lowered hypothalamic 5-HT and augmented basal corticoid secretion; however, after "ether stress" there was no response

either in hypothalamic 5-HT content or adrenal function. In any event, the results suggest that "the changes induced in the stress mechanism by different drugs are related to their action on the hypothalamic serotonin level. Its increase inhibits while its decrease facilitates the stress-induced activation of pituitary-adrenal function."

Hara, M.: "Gastroduodenal ulcers in dogs produced by electric stress after reserpinization." *Nihon Univ. J. Med.* **16**: 119-128 (1974). J15,282/74

The production of gastroduodenal ulcers by electric stimulation in reserpine-pretreated dogs is ascribed to the peptic action of gastric juice upon a mucosa damaged by angiotensin. Special attention is given to Japanese literature that is unavailable in English (24 refs.).

Johnson, T. H., Tharp, G. D.: "The effect of chronic exercise on reserpine-induced gastric ulceration in rats." *Med. Sci. Sports* **6**: 188-190 (1974). J16,755/74

A study on cross-resistance in rats, using reserpine-induced gastric ulcers as an indicator of stress, and using forced running in a treadmill or swimming as a second stressor. "The degree of ulceration of the glandular portion of the stomach produced by administration of reserpine was significantly lower in treadmill runners than in their controls, however, the degree of ulceration for the swimmers was not significantly different from that of their controls.... It might be that the swimmers were still in Selye's 'stage of resistance' and not quite in the 'trained state.' Thus, the corticosterone level may have still been higher than normal and may have contributed to the increased ulceration in the swimmers" (19 refs.).

Ricin. Balint, G. A.: "Examination of the inflammatory effect of ricin with special reference to the endogenous corticosteroid mobilisation." *Toxicology* **1**: 329-336 (1973). J10,650/73

Topical arthritis is produced by injection of ricin into the hind foot pad of the rat. If ricin is injected intraperitoneally it increases plasma corticoids and causes degranulation of the adrenals with inhibition of the anaphylactoid edema induced by dextran.

***Salicylates.** George, R., Way, E. L.: "The hypothalamus as an intermediary for pituitary-adrenal activation by aspirin." *J. Pharmacol. Exp. Ther.* **119**: 310-316 (1957). C34,580/57

In rats, lesions of the ME completely blocked adrenal ascorbic acid depletion following treatment with large doses of acetylsalicylic acid.

***Tranquilizers.** (See also under names of individual tranquilizers) Sabshin, M., Eisen, S. B.: "The effects of ward tension on the quality and quantity of tranquilizer utilization." *Ann. N.Y. Acad. Sci.* **67**: 746-757 (1956). J10,382/56

Riley, H., Spinks, A.: "Biological assessment of tranquillisers. Part I." *J. Pharm. Pharmacol.* **10**: 657-671 (1958). G79,395/58

Review on the assay of tranquilizers with an extensive section on their effect upon stress reactions (202 refs.).

Oyama, T., Kimura, K., Takazawa, T., Takiguchi, H.: "An objective evaluation of tranquillizers as preanaesthetic medication: effect on adrenocortical function." *Can. Anaesth. Soc. J.* **16**: 209-216 (1969). J11,007/69

"While placebo had no measurable effects, diazepam and nitrazepam clearly decreased plasma free cortisol levels at 8:30 am. and hydroxyzine significantly reduced the value at 8:00 am. The sedative effects of these tranquillizing agents and the ineffectiveness of the placebo definitely correlated with the alterations in plasma cortisol levels" (11 refs.).

Lidbrink, P., Corrodi, H., Fuxé, K., Olson, L.: "Barbiturates and meprobamate: decreases in catecholamine turnover of central dopamine and noradrenaline neuronal systems and the influence of immobilization stress." *Brain Res.* **45**: 507-524 (1972). G95,413/72

Costa, E., Meek, J. L.: "Regulation of biosynthesis of catecholamines and serotonin in the CNS." *Ann. Rev. Pharmacol.* **14**: 491-511 (1974). J12,127/74

Review on catecholamine and 5-HT synthesis in the nervous system under various conditions including stress. "Benzodiazepines (minor tranquilizers) block the increase in NEP turnover produced by stress, in doses devoid of any effect on amine turnover in normal animals. One of the mechanisms discussed above might be directly affected by the benzodiazepines, but they might directly affect another system of neurons that in stress influence noradrenergic neurons" (161 refs.).

***Vitamins.** Thayer, W. R., Toffler, A. H., Chapo, G., Spiro, H. M.: "Inhibition of restraint ulcers in the rat by pyridoxine deficiency." *Yale J. Biol. Med.* **38**: 257-264 (1965). G37,375/65

In rats, pyridoxine deficiency decreases the incidence of restraint ulcers and depresses gastric secretion. "It is suggested that since pyridoxine deficiency lowers histamine-forming capacity, this reduction in endogenous histamine leads to a decrease in acid production which then protects against restraint ulcers."

Moritz, E., Zacherl, H., Onderscheka, K., Helsberg, A.: "Vitamin A und Stressulkus-Prophylaxe" (The effect of vitamin A on endotoxin-induced stress ulcers). *Brunn Beitr. Klin. Chir.* **221**: 208-221 (1974).

J13,239/74

In rats, the incidence of endotoxin-induced stress ulcers of the stomach can be reduced by vitamin A. Despite virtually unchanged plasma and liver levels of the vitamin, its concentration in the gastric wall was significantly increased after treatment.

***Various Drugs or Drug Combinations**
not previously mentioned. Brenner, R. M.: "Radioautographic studies with tritiated thymidine of cell migration in the mouse adrenal after a carbon tetrachloride stress." *Am. J. Anat.* **112**: 81-86 (1963). D56,443/63

In mice stressed by subcutaneous carbon tetrachloride, ^3H -thymidine was given to study its incorporation into DNA-synthesizing cells by stripping film autoradiography. "Labeled cells were initially distributed at the periphery of the cortex scattered between the glomerulosa and the upper fasciculata, but within four to six weeks heavily labeled cells were found deep within the cortex indicating that centripetal migration had occurred. The upper fasciculata was judged to be a region of maximum cell turnover from which cells had migrated centripetally, but migration of cells from the glomerulosa seemed to be minimal."

Lorenzen, L. C., Ganong, W. F.: "Effect of drugs related to α -ethyltryptamine on stress-induced ACTH secretion in the dog." *Endocrinology* **80**: 889-892 (1967). F83,263/67

In dogs, α -methyltryptamine suppressed ACTH secretion as effectively as did α -ethyltryptamine. Corresponding tests with numerous indole derivatives, MAO inhibitors, antidepressants and pressor amines revealed

that the ACTH blocking activity of α -methyltryptamine is correlated only with its pressor action, since it is shared by vasopressors. The effect is unrelated to any other chemical or pharmacologic property of the drugs used for comparison.

Scapagnini, U., Preziosi, P.: "Role of brain norepinephrine and serotonin in the tonic and phasic regulation of hypothalamic-hypophyseal adrenal axis." *Arch. Int. Pharmacodyn. Ther.* **196** Suppl.: 205-220 (1972).

H56,654/72

Survey of the literature plus the extensive experiments of the authors and their co-workers led to the following main conclusions: (1) there is an adrenergic system in the brain which inhibits ACTH secretion. Drugs that release active catecholamines from nerve endings block ACTH discharge if they can pass the blood-brain barrier or are injected directly into the third ventricle or ME. Stressors deplete brain NEP and increase ACTH secretion. Admittedly, the amount of drugs necessary for inhibition is large compared to the normal catecholamine levels present in the brain; hence, their action is of doubtful physiologic significance. They may act merely by constricting the portal vessels so that CRF cannot reach an adequate concentration in the adenohypophysis. Among the drugs used to explore the ACTH inhibitory adrenergic mechanism were: amphetamine, α_1 -ethyltryptamine, L-dopa, tyramine, α -MT, guanethidine, FLA-63 (an inhibitor of dopamine- β -oxidase), L-threo-dihydroxy-phenyl-serine or DOPS (which selectively repletes NEP after depletion of NEP and dopamine by α -MT), phenolamine (an α -blocking agent) and so on. (2) 5-HT appears to regulate the circadian variations of ACTH secretion by the limbic system. Its concentration is especially high in the raphé nuclei (containing the greatest number of serotonergic cell bodies), particularly the amygdala and hippocampus in which it shows circadian variations. Destruction of these nuclei abolishes the circadian plasma corticosterone rhythm.

Mogilner, B. M., Freeman, J. S., Blashar, Y., Pincus, F. E.: "Reye's syndrome in three Israeli children. Possible relationship to warfarin toxicity." *Isr. J. Med. Sci.* **10**: 1117-1125 (1974). H96,872/74

On the basis of clinical observations, "warfarin is added to the list of factors predisposing to or causing the extreme acute stress."

Hormones and Hormone-like Substances

Catecholamines, particularly EP and NEP, are strong stressors when given in large doses. They elicit all the characteristic manifestations of the stress syndrome, such as eosinopenia, adrenocortical stimulation with an increase in adrenal size, loss of cortical lipids, and a rise in blood ACTH levels. Most of these effects are discussed at greater length in the section on the mechanism of the stress response, since catecholamine discharge (from the sympathetic nerve endings, the adrenal medulla, from extra-adrenal and particularly from hypothalamic cells) is an essential part of it.

Suffice it to mention here a few unconfirmed special observations which at first sight appear to be paradoxical. Allegedly, in mice, EP-induced adrenocortical lipid discharge can be prevented by small doses of vasopressin. This is all the more unexpected since vasopressin itself is a strong activator of the pituitary-adrenocortical axis.

In eviscerated and decapitated dogs, EP has been said to stimulate corticoid secretion despite the absence of the hypophysis and independently of any change in the vascularization of the adrenals. This claim was based on insufficient evidence and has never been confirmed.

Large doses of *mineralocorticoids* produce experimental replicas of cardiovascular diseases and hypertension, such as are also elicited by prolonged exposure to certain stressors, especially in animals receiving proper conditioning (for example, high sodium chloride diets, unilateral nephrectomy). An excess of *glucocorticoids* usually enhances the production of stress ulcers. All these effects will be dealt with in greater detail in the section on experimental models of diseases of adaptation. It is worth mentioning here, however, that under certain conditions restraint ulcers can be prevented in rats by glucocorticoids. The mechanism of this apparently paradoxical effect is not known.

Glucagon, added to rat pituitary homogenates, inhibits ACTH concentration in the medium, perhaps because of ACTH destruction or a diminution of its production.

Gonadotropic and *gonadal hormones* do not exert any conspicuous stressor effect, although they may influence the stress response elicited by other agents. Estrogens are especially notorious for their marked adrenocortical stimulating action and the thymicolympathic and splenic involution which they produce at relatively low dose levels.

Prepubertal ovariectomy decreases ACTH secretion, allegedly through a diminution of pituitary sensitivity to CRF stimulation and a decreased capacity to synthesize ACTH. Precocious puberty induced by gonadotropic hormones in female rats stimulates adrenocortical function and sensitivity to "ether stress."

Insulin, given in hypoglycemic doses, is a strong stressor which causes eosinopenia, adrenocortical stimulation and a rise in plasma STH. On the other hand, the pituitary concentration of STH is diminished by insulin (as it is by various other stressors, such as EP, vasopressin, cold). This effect of insulin hypoglycemia is prevented by dexamethasone and is ascribed to the stressor action of hypoglycemia.

In rats with chronic ME lesions, the *thyroid hormones*, T_3 and T_4 , increase adrenal weight without correcting pituitary or ovarian atrophy. Basal ACTH secretion remains appreciable after ME destruction and can be enhanced by hyperthyroidism. The fact that thiouracil interferes with TTH secretion without inhibiting the production of ACTH shows that the two mechanisms are independent.

Vasopressin is almost as potent as CRF in stimulating ACTH discharge and acts as a strong stressor. This is true both of natural and of synthetic preparations. The matter will be discussed at length in the section on the mechanism of stress responses.

Large doses of both *histamine* and *5-HT* produce definite stress responses.

Hormones and Hormone-like Substances

(See also our earlier stress monographs, p. xiii)

Angiotensin. (See Renin)

Catecholamines. Marañon, G.: "Contribution à l'étude de l'action émotive de l'adrénaline" (Contribution to the study of emotive actions of adrenaline). *Rev. Fr. Endocrinol.* **2**: 301-325 (1924). 87,752/24

Description of various emotional responses to EP in man. Depending upon individual variations, these responses may be characterized by trembling, crying, salivation, sweating, blushing, pallor, palpitations, moaning, shivering, polyuria, diarrhea, gastrointestinal spasms, hypertension, hyperglycemia, glycosuria and other somatic manifestations.

Landis, C., Hunt, W. A.: "Adrenalin and emotion." *Psychol. Rev.* **39**: 467-485 (1932). 8,333/32

Early observations on emotional changes produced by EP in some but not in other individuals, depending upon their predisposition.

Vogt, M.: "Observations on some conditions affecting the rate of hormone output by the suprarenal cortex." *J. Physiol. (Lond.)* **103**: 317-332 (1944). B897/44

In eviscerated dogs and cats, intravenous infusion of EP causes intense stimulation of corticoid secretion which is allegedly direct and not mediated through the pituitary. [The latter statement is based on observations on a single decapitated dog (H.S.).] This effect is obtained with physiologic doses of EP and is of the order of several times the normal corticoid output. The action is independent of blood pressure and blood flow.

Vogt, M.: "Cortical lipids of the normal and denervated suprarenal gland under conditions of stress." *J. Physiol. (Lond.)* **106**: 394-404 (1947). B26,537/47

Repeated injections of EP in rats and cats caused conspicuous degranulation of the adrenal cortical cells. This degranulation is ascribed to stress and cannot be prevented by adrenal denervation.

Laragh, J. H., Almy, T. P.: "Changes in circulating eosinophils in man following epinephrine, insulin, and surgical operations." *Proc. Soc. Exp. Biol. Med.* **69**: 499-501 (1948). B31,814/48

In man, surgical trauma and injections of EP and insulin caused eosinopenia.

Recant, L., Hume, D. M., Forsham, P. H.,

Thorn, G. W.: "Studies on the effect of epinephrine on the pituitary-adrenocortical system." *J. Clin. Endocrinol.* **10**: 187-229 (1950). B47,003/50

"A simple clinical test for the evaluation of pituitary-adrenocortical integrity is presented, based on the four-hour fall in circulating eosinophils following the subcutaneous injection of 0.3 mg. of epinephrine or the intravenous administration of 0.2 mg. in 200 cc. of saline over a one-hour period. A fall exceeding 50 per cent excludes both adrenocortical and pituitary ACTH deficiency."

Humphreys, R. J., Raab, W.: "Response of circulating eosinophils to norepinephrine, epinephrine and emotional stress in humans." *Proc. Soc. Exp. Biol. Med.* **74**: 302-303 (1950). B49,646/50

In medical students, the stress of an examination caused profound eosinopenia. This reaction was much more readily duplicated by EP than by NEP.

Farrell, G. L., McCann, S. M.: "Detectable amounts of adrenocorticotropic hormone in blood following epinephrine." *Endocrinology* **50**: 274-276 (1952). B69,080/52

In rats, EP causes a particularly rapid and pronounced increase in blood ACTH.

Nelson, D. H., Sandberg, A. A., Palmer, J. G., Glen, E. M.: "Levels of 17-hydroxycorticosteroids following intravenous infusion of epinephrine into normal men." *J. Clin. Endocrinol. Metab.* **12**: 936 (1952). B71,939/52

Basowitz, H., Korchin, S. J., Oken, D., Goldstein, M. S., Gussack, H.: "Anxiety and performance changes with a minimal dose of epinephrine." *Arch. Neurol. Psychiatry* **76**: 98-105 (1956). J12,074/56

Medical interns receiving constant infusions of EP (5γ per kg. body weight per hour) showed moderate increases in pulse rate and blood pressure. Among performance tests only motor tasks were significantly affected. The emotional responses demonstrated considerable individual variations.

Kitay, J. I., Holub, D. A., Jailer, J. W.: "'Inhibition' of pituitary ACTH release after administration of reserpine or epinephrine." *Endocrinology* **65**: 548-554 (1959). C74,892/59

In rats, single injections of EP or reserpine produced an ACTH discharge, yet "the acute release of ACTH in response to the stress of ether anesthesia was found to be diminished or absent after a single injection

of epinephrine or after multiple injections of either reserpine or epinephrine. These data are consistent with the hypothesis that the amount of pituitary ACTH available for immediate release in response to acute stress is reduced after administration of reserpine or epinephrine, whereas chronic hypersecretion of ACTH remains unimpaired."

Frankenhaeuser, M., Järpe, G.: "Psychophysiological changes during infusions of adrenaline in various doses." *Psychopharmacologia* **4**: 424-432 (1963). E26,806/63

Kurokawa, M.: "Effect of posterior pituitary hormone on adrenal cortical lipids." *Nagoya J. Med. Sci.* **20**: 23-30 (1967).

E53,885/67

In mice, the adrenal cortical lipid depletion produced by EP or cold could be prevented by pretreatment with small doses of vasopressin. The lipid-depleting effect of ACTH was not affected by such pretreatment.

Dechezleprêtre, S., Lechat, P.: "Effets comparés de l'adrénaline et d'un stress aigu sur la glycémie, la lactacidémie et la corticostérone plasmatique et surrénalienne du rat" (Comparison of the effects of epinephrine and acute stress on glycemia, lactacidemia and the corticosterone levels of plasma and the adrenals of the rat). *Aggressologie* **15**: 117-123 (1974). H93,830/74

In rats, acute exposure to cold causes marked hyperlactacidemia and mild hyperglycemia, with a considerable increase in plasma and adrenal corticosterone levels. These changes reach their maximum within ten minutes. EP exerts a similar effect due to the stressor action of the injection procedure, since it is also produced by injection of the solvent alone. The changes elicited by combined treatment with cold and EP are not greater than those caused by the two agents separately.

Zachariassen, R. D., Newcomer, W. S.: "Phenylethanolamine-N-methyl transferase activity in the avian adrenal following immobilization or adrenocorticotropin." *Gen. Comp. Endocrinol.* **23**: 193-198 (1974).

H88,608/74

In cockerels, ACTH or immobilization resulted in an increase of plasma EP and NEP with an accompanying decrease in the adrenal levels of these catecholamines; plasma corticosterone also rose as did the phenylethanolamine-N-methyl transferase (PNMT) content of the adrenals without affecting adrenal

corticosterone. "It is suggested that the rapid increase in PNMT activity, occurring with the acute application of stressors in chickens, may provide a means of sustaining an increased outflow of EP in times of 'stress.'" Corticosterone may play a role in the elevation of PNMT during the avian stress response.

Corticoids. Selye, H.: "Effect of desoxycorticosterone upon the toxic actions of somatotrophic hormone." *Proc. Soc. Exp. Biol. Med.* **76**: 510-515 (1951).

B54,470/51

In uninephrectomized rats kept on a high sodium intake, STH produces cardiac hypertrophy, myocarditis, hypertension, nephrosclerosis and polyuria similar to the syndrome elicited by DOC. When STH and DOC are given simultaneously, all these effects are greatly increased, except for the hypertension which may be inhibited as a consequence of the pronounced edema and obvious physical deterioration. It is possible that even purified STH stimulates the adrenal cortex or activates mineralocorticoids.

Schapiro, S.: "Androgen treatment in early infancy: effect upon adult adrenal cortical response to stress and adrenal and ovarian compensatory hypertrophy." *Endocrinology* **77**: 585-587 (1965). F49,822/65

One-day-old female rats given 1 mg. testosterone subsequently developed the expected persistent estrus syndrome. The response to stress (ether) was normal in both sexes although the extent of compensatory adrenal hypertrophy appeared to be less after testosterone pretreatment. An addendum notes that "neonatal treatment with 1 mg cortisol has been subsequently observed to produce a fertile 'corticoid runt' with a normal adrenal cortical response to stress."

Robert, A., Phillips, J. P., Nezamis, J. E.: "Production, by restraint, of gastric ulcers and of hydrothorax in the rat." *Gastroenterology* **51**: 75-81 (1966). G40,473/66

In rats, restraint produced gastric ulcers and hydrothorax within four to six hours. Overnight fasting prevented the hydrothorax and reduced gastric ulcerations (contrary to previous reports). Restraint ulcers and hydrothorax "were also inhibited by crowding of the animals, a rise in ambient temperature, or administration of prednisolone."

Glucagon. Barrett, A. M., Sayers, G.: "Loss of ACTH activity following incubation

of pituitary tissue: inhibition by glucagon and by pitressin." *Endocrinology* **62**: 637-645 (1958). C52,314/58

In rat pituitary homogenates, ACTH activity rapidly disappears, presumably owing to destruction of the hormone by proteolytic enzymes. Addition of glucagon or vasopressin to the incubates inhibits this effect. In tests for CRF activity it must be kept in mind that "substances added to the medium of incubated pituitaries may increase the quantity of ACTH in the medium by inhibition of ACTH destruction as well as by stimulation of release from adenohypophyseal cells."

Hinterberger, H., Wilcken, D. E. L.: "The effect of prolonged glucagon infusions on the urinary excretion of catecholamines and 4-hydroxy-3-methoxymandelic acid and on adrenal medullary tissue levels of catecholamines in patients with severe cardiac disease." *Clin. Chim. Acta* **52**: 153-161 (1974). J12,410/74

In patients with congestive heart failure, unphysiologically high doses of glucagon promote catecholamine synthesis and storage in the adrenal medulla (26 refs.).

Gonadotropic and Gonadal Hormones. Schapiro, S.: "Androgen treatment in early infancy: effect upon adult adrenal cortical response to stress and adrenal and ovarian compensatory hypertrophy." *Endocrinology* **77**: 585-587 (1965). F49,822/65

One-day-old female rats given 1 mg. testosterone subsequently developed the expected persistent estrous syndrome. The response to stress (ether) was normal in both sexes although the extent of compensatory adrenal hypertrophy appeared to be less after testosterone pretreatment. An addendum notes that "neonatal treatment with 1 mg cortisol has been subsequently observed to produce a fertile 'corticoid runt' with a normal adrenal cortical response to stress."

Coyne, M. D., Kitay, J. I.: "Effect of ovariectomy on pituitary secretion of ACTH." *Endocrinology* **85**: 1097-1102 (1969). H19,815/69

Experiments on rats "indicate that prepuberal ovariectomy results in decreased pituitary secretion of ACTH. The hyposecretion is related to a decreased sensitivity of the pituitary to CRF stimulation and a decreased pituitary capacity to synthesize ACTH. Moreover, the lower levels of plasma ACTH in adrenalectomized, ovariectomized

rats suggest that the effects of estradiol are independent of corticosteroid feedback."

Eiff, A. W. von, Plotz, E. J., Beck, K. J., Czernik, A.: "The effect of estrogens and progestins on blood pressure regulation of normotensive women." *Am. J. Obstet. Gynecol.* **109**: 887-892 (1971). G81,851/71

Both folliculoids and luteoids enhance the rise in blood pressure, respiratory rate and muscle tone in ovariectomized women performing a simple arithmetic task with or without noise.

Rodier, W. I., Kitay, J. I.: "The influence of progesterone on adrenocortical function in the rat." *Proc. Soc. Exp. Biol. Med.* **146**: 376-380 (1974). H87,653/74

In rats treated in vivo with progesterone, production of corticosterone in their adrenal homogenates was decreased.

Ramaley, J. A., Olson, J.: "Adrenal function in rats given PMS before puberty: response to ether stress." *Neuroendocrinology* **14**: 1-13 (1974). H83,081/74

Induction of precocious puberty by gonadotropic hormone in female rats stimulates adrenocortical function as indicated by an increase in blood corticosterone after "ether stress."

Schlein, P. A., Zarrow, M. X., Denenberg, V. H.: "The role of prolactin in the depressed or 'buffered' adrenocorticosteroid response of the rat." *J. Endocrinol.* **62**: 93-99 (1974). H90,051/74

The diminished corticosterone secretion of lactating rats under stress is due to a blockade produced by increased LTH levels.

Dunn, J. D.: "Pituitary-adrenal function in adult androgenized female rats." *Proc. Soc. Exp. Biol. Med.* **146**: 75-77 (1974). H87,171/74

Neonatal treatment with testosterone did not markedly affect the pituitary-adrenal response of female rats to ether stress in adult life.

Histamine and 5-HT. Weltman, A. S., Sackler, A. M.: "Effect of lysergic acid diethylamide (LSD-25) on growth, metabolism and the resistance of male rats to histamine stress." *J. Pharm. Sci.* **54**: 1382-1384 (1965). F49,487/65

Kawai, A., Yates, R. E.: "Interference with feedback inhibition of adrenocorticotropin release by protein binding of corticoste-

rone." *Endocrinology* **79**: 1040-1046 (1966).
F74,052/66

In rats, intravenous histamine causes nearly maximal ACTH release, as indicated by plasma and adrenal corticosterone. If given intravenously before histamine, unbound corticosterone impairs ACTH secretion, but does not if injected in the presence of corticosterone-binding plasma proteins. It is not certain, however, that impairment of the negative feedback action of corticosterone by its binding proteins is present at low corticosterone concentrations.

Kakihana, R., Blum, S., Kessler, S.: "Developmental study of pituitary-adrenocortical response in mice: plasma and brain corticosterone determination after histamine stress." *J. Endocrinol.* **60**: 353-358 (1974).

H83,418/74

In newborn mice, histamine caused a rise in plasma corticosterone between the sixteenth and twenty-first days of life but not between the third and eleventh days. In the younger group, corticosterone levels in the brains of nonstressed controls were much higher than those in the older animals. Histamine significantly increased brain corticosterone during both periods, particularly in the stress-responsive older mice.

Insulin. Laragh, J. H., Almy, T. P.: "Changes in circulating eosinophils in man following epinephrine, insulin, and surgical operations." *Proc. Soc. Exp. Biol. Med.* **69**: 499-501 (1948).
B31,814/48

In man, surgical trauma and injections of EP or insulin caused eosinopenia.

Hales, W. M., Simon, W.: "Minnesota multiphasic personality inventory patterns before and after insulin shock therapy." *Am. J. Psychiatry* **105**: 254-258 (1948).

B59,134/48

Bliss, E. L., Migeon, C. J., Nelson, D. H., Samuels, L. T., Branch, C. H. H.: "Influence of E.C.T. and insulin coma on level of adrenocortical steroids in peripheral circulation." *Arch. Neurol. Psychiatry* **72**: 352-361 (1954).
C1,997/54

In schizophrenics, electroconvulsive therapy as well as insulin coma increased the plasma level of 17-OHCS. When diphenylhydantoin was used to eliminate cyanosis, apnea and violent muscular movements, seizures still resulted in a rise of corticoids, but of shortened duration.

Bliss, E. L., Migeon, C. J., Branch, C.

H. H., Samuels, L. T.: "Reaction of the adrenal cortex to emotional stress." *Psychosom. Med.* **18**: 56-76 (1956). C13,032/56

In normal people and psychiatric patients emotional stress (subjectively estimated by manifestations of anxiety and tension), whether occurring spontaneously or elicited experimentally, caused consistent but very modest increases of 17-OHCS in blood and urine. These changes were always much less pronounced than those produced by ACTH, Piromen, insulin, electroshock or moderate physical exercise.

Skaug, O. E., Lingjaerde, P.: "The effect of insulin on blood sugar, electrolytes, plasma 17-hydroxycorticosteroids, and circulating eosinophils in adult women." *Scand. J. Clin. Lab. Invest.* **12**: 71-75 (1960).

C86,714/60

Landon, J., Wynn, V., James, V. H. T.: "The adrenocortical response to insulin-induced hypoglycemia." *J. Endocrinol.* **27**: 183-192 (1963). E33,724/63

The rise in plasma cortisol induced in man by insulin is recommended as a quick and simple test for stress responsiveness.

Roth, J., Glick, S. M., Yalow, R. S., Berzon, S. A.: "Hypoglycemia: a potent stimulus to secretion of growth hormone." *Science* **140**: 987-988 (1963). D66,637/63

Hunter, W. M., Clarke, B. F., Duncan, L. J. P.: "Plasma growth hormone after an overnight fast and following glucose loading in healthy and diabetic subjects." *Metabolism* **15**: 596-607 (1966). F68,199/66

In healthy and diabetic patients glucose loading diminishes plasma STH concentrations, but this is followed by a rise during the subsequent drop in blood sugar. [These observations suggest that insulin-induced increases in plasma STH may not be true stress effects but are specific results of hypoglycemia (H.S.).]

Müller, E. E., Saito, T., Arimura, A., Schally, A. V.: "Hypoglycemia, stress and growth hormone release: blockade of growth hormone release by drugs acting on the central nervous system." *Endocrinology* **80**: 109-117 (1967). F75,362/67

The pituitary STH content (tibia test) was diminished by various stressors (EP, vasoressin, urecholine, cold, insulin). This effect of insulin hypoglycemia was prevented by dexamethasone, and it was assumed that the discharge of pituitary STH "observed after

insulin administration may reflect a nonspecific stress effect of the hypoglycemic stimulus."

Marks, V., Greenwood, F. C., Howorth, P. J. N., Samols, E.: "Plasma growth hormone levels in spontaneous hypoglycemia." *J. Clin. Endocrinol. Metab.* **27**: 523-528 (1967). F82,109/67

In patients with insulinomas, fasting hypoglycemia raises plasma STH levels. On the other hand, "spontaneous hypoglycemia" and that produced by overnight fasting cause no rise in plasma STH even if blood sugar concentrations are very low. "Insulin-induced hypoglycemia may therefore be interpreted as a 'stress' stimulus." This might explain why the highest values for fasting plasma STH were more closely related to the presence of subjective symptoms than to the absolute blood glucose concentrations. Possibly, the stressor effect of insulin hypoglycemia depends on a deficit in cerebral glucose, since other investigators have shown that glucocorticoids, well known to increase cerebral tolerance to hypoglycemia, tend to diminish STH secretion after insulin.

Plumpton, F. S., Besser, G. M.: "The adrenocortical response to surgery and insulin-induced hypoglycaemia in corticosteroid-treated and normal subjects." *Br. J. Surg.* **56**: 216-219 (1969). H9,868/69

In patients undergoing major surgery or experiencing insulin hypoglycemia, concurrent prednisolone administration usually, but not always, failed to develop the increase in plasma corticoids normally elicited by these stressors, but only for a limited length of time.

Daly, J. R., Fleisher, M. R., Chambers, D. J., Bitensky, L., Chayen, J.: "Application of the cytochemical bioassay for corticotrophin to clinical and physiological studies in man." *Clin. Endocrinol. (Oxford)* **3**: 335-345 (1974). H88,166/74

In rheumatoid arthritics chronically treated with ACTH, insulin hypoglycemia causes a subnormal rise in plasma ACTH, and yet the plasma cortisol level is identical to that in control subjects. Presumably, the adrenal in ACTH-treated patients is hypersensitive and responds to subnormal amounts of ACTH with an enhanced cortisol secretion. However, the difference is very slight, and only the rate of response measured by the slope of the steepest part of the curve differs significantly. Hence, strong ACTH treatment

alters only the rate of ACTH release in response to hypoglycemia, not the total amount secreted. In contrast, prolonged corticoid treatment greatly reduces the ACTH secretion following insulin hypoglycemia.

Pineal Hormones. Golikov, P. P., Konushko, S. D.: "The effect of the extracts of the epiphysis on the content of 11-OCS in the peripheral blood of rats." *Probl. Endokrinol.* **20** No. 3: 81-85 (1974) (Russian). H92,319/74

In rats, pineal extracts administered intraperitoneally increased plasma 11-OHCS levels but only in the presence of the pituitary. [Presumably, they produced distress (H.S.).]

Renin, Angiotensin. Gal, T. J., Cooperman, L. H., Berkowitz, H. D.: "Plasma renin activity in patients undergoing surgery of the abdominal aorta." *Ann. Surg.* **179**: 65-69 (1974). J9,433/74

Surgical anesthesia sufficed to increase plasma renin activity, but a further rise was noted following subsequent insertion of an aortic bifurcation graft and release of the cross clamped aorta. [The observations do not permit differentiation between the relative roles of stress and the specific operative procedure (H.S.).]

STH. Selye, H.: "Effect of desoxycorticosterone upon the toxic actions of somatotrophic hormone." *Proc. Soc. Exp. Biol. Med.* **76**: 510-515 (1951). B54,470/51

In uninephrectomized rats kept on a high sodium intake, STH produces cardiac hypertrophy, myocarditis, hypertension, nephrosclerosis and polyuria similar to the syndrome elicited by DOC. When STH and DOC are given simultaneously all these effects are greatly increased, except for hypertension, which may be inhibited as a consequence of the pronounced edema and obvious physical deterioration. It is possible that even purified STH stimulates the adrenal cortex or activates mineralocorticoids.

Thymus Hormones. Deschaux, P., Flores, J. L., Fontanges, R.: "Influence de la thymectomie sur les glandes surrenales. Opothérapie de substitution à l'aide d'extraits thyminiques" (Influence of thymectomy on the adrenals. Substitutive ootherapy with thymus extracts). *Arch. Int. Physiol.* **82**: 115-121 (1974). J13,829/74

Neonatal thymectomy in mice causes decreased adrenal activity (as indicated by

oxygen consumption of the gland in vitro). This effect is allegedly compensated for by administration of the thymus extract "thymosine," and is interpreted to show a regulatory effect of the thymus upon the adrenals. [This interpretation requires confirmation (H.S.).]

Thyroid Hormones. Bogdanov, E. M., Halmi, N. S.: "Effects of hypothalamic lesions and subsequent propylthiouracil treatment on pituitary structure and function in the rat." *Endocrinology* **53**: 274-292 (1953).

B86,246/53

In rats with lesions in diverse parts of the hypothalamus, administration of thiouracil inhibited adrenal and/or thyroid enlargement, but the number of animals was small and adrenal size was too variable to draw definite conclusions on the exact location of the various regulating centers.

McGuire, J. S. Jr., Tomkins, G. M.: "The effects of thyroxin administration on the enzymic reduction of Δ^4 -3-ketosteroids." *J. Biol. Chem.* **234**: 791-794 (1959).

E90,938/59

In vitro observations in rats suggest that thyroxine increases Δ^4 -3-ketosteroid reduction "(a) by causing an increase in available reduced triphosphopyridine nucleotide which is a rate-determining reactant in this process, and (b) by causing an increase in a steroid 5α -hydrogenase in liver microsomes.

D'Angelo, S. A., Young, R.: "Chronic lesions and ACTH: effects of thyroid hormones and electrical stimulation." *Am. J. Physiol.* **210**: 795-800 (1966). F63,559/66

In rats with chronic ME lesions, T_3 and T_4 increased adrenal weight without correcting pituitary and ovarian atrophy, decreased the adrenal and ovarian ascorbic acid contents, and elevated the plasma and adrenal corticoids. Electric stimulation of the anterior hypothalamus in intact rats caused ACTH release and this was blocked by the ME lesions. Basal ACTH discharged following destruction of the ME remained appreciable and could be enhanced by hyperthyroidism. Presumably, "neural stimuli from the rostral hypothalamus mediate their effects on ACTH release via the median eminence; and augmentation of ACTH secretion in severe hyperthyroidism involves a non-neural, humoral metabolic pathway."

Labrie, F., Raynaud, J. P., Pelletier, G., Ducommun, P., Fortier, C.: "Corticosterone-

binding by transcartin and pituitary-thyroid-adrenocortical interactions in the rat." In: Jasmin, G., *Endocrine Aspects of Disease Processes*, pp. 20-26. St. Louis, Mo.: Warren H Green, 1968. E7,614/68

In rats, graded doses of thyroxine cause progressive increases in adrenal weight, presumably as a consequence of augmented ACTH secretion. At the same time, there is a stepwise elevation of total plasma corticosterone without a significant alteration in the absolute level of the unbound fraction. Presumably, only free corticosterone is responsible for the feedback mechanism, while the binding capacity of transcartin accounts for adjustments in the rate of corticosterone secretion to changes in thyroid activity. Furthermore, "thyroxine alone has a direct enhancing effect on the binding capacity of transcartin" and "the stimulating effect of estrogen and progesterone is exerted through the pituitary-thyroid axis."

Németh, S., Vigáš, M., Mikulaj, L.: "Changed response of the plasma corticosterone level to Noble-Collip drum trauma in non conditioned and conditioned rats after treatment with thyroxine and after thyroidectomy." *Endocrinol. Exp.* **5**: 179-184 (1971). H47,156/71

In rats pretreated with thyroxine, plasma corticosterone levels were high and showed an exaggerated increase after Noble-Collip drum trauma. The reverse was true after thyroidectomy.

Meserve, L. A., Leathem, J. H.: "Hypothyroidism and the maturation of the hypothalamo-hypophyseal-adrenal axis." *Dev. Psychobiol.* **6**: 123-129 (1973).

J2,516/73

In rats made hypothyroid by feeding thiouracil to the mothers during pregnancy and lactation, the adrenal and serum corticosterone levels were normal. However, "ether stress" failed to elicit an increased synthesis of corticosterone in the hypothyroid rat, although the response to ACTH was normal. Presumably, neonatal hypothyroidism retards the maturation of the hypothalamus-pituitary axis.

Rosolovskii, A. P.: "The effect of the thyroid gland on the appearance of trophic afflictions of the stomach during the action of stress and steroids." *Probl. Endokrinol.* **20** No. 5: 70-72 (1974) (Russian).

H95,571/74

In rats, "the ulcerogenic action of stress and steroids increased considerably in experimental hyperthyroidism, and was markedly diminished in hypothyroidism."

Vasopressin. Bertelli, A., Martini, L.: "Caduta dell'acido ascorbico surrenalico in animali trattati con ormoni postipofisari—Nota 3" (Adrenal ascorbic acid depletion in animals treated with posthypophyseal hormones—Note 3). *Atti Soc. Lomb. Sci. Med. Biol.* 7: 430-432 (1952). B77,331/52

In intact rats both oxytocin and vasopressin cause adrenal ascorbic acid depletion, but since this response is inhibited by hypophsectomy it must be ascribed to a discharge of pituitary ACTH.

Arimura, A.: "The effect of posterior-pituitary hormone on the release of ACTH." *Jap. J. Physiol.* 5: 37-44 (1955).

C6,604/55

Although large doses of vasopressin cause adrenal ascorbic acid depletion in the rat, pretreatment with small doses actually prevents the release of ACTH provoked by EP, histamine or cold.

Kurokawa, M.: "Effect of posterior pituitary hormone on adrenal cortical lipids."

Nagoya J. Med. Sci. 20: 23-30 (1967).

E53,885/67

In mice, the adrenal cortical lipid depletion produced by EP or cold could be prevented by pretreatment with small doses of vasopressin. The lipid-depleting effect of ACTH was not affected by such pretreatment.

Simionescu, S.: "L'action pharmacodynamique non spécifique de l'ADH (8-lysine-vasopressine)" (Nonspecific pharmacodynamic effects of ADH [8-lysine-vasopressin]). *Rev. Roum. Physiol.* 10: 349-352 (1973).

J8,130/73

Brief survey of the stressor effects of synthetic lysine-vasopressin (15 refs.).

Pai, S. R.: "Influence of oxytocin on pituitary-adrenal-gonad relationship and on the development of mammary tumours in C₃H mice." *Indian J. Med. Res.* 61: 1810-1817 (1973).

J13,044/73

The synthetic oxytocin, Syntocinon, failed to cause morphologic changes in the gonads and adrenals of two strains of mice. Yet "loss of weight of thymus was seen in intact C₃H mice immediately after Syntocinon treatment, however, in C₁₇ thymus was not responsive to this treatment."

Diet

The fact that acute and complete starvation produces a typical stress response was emphasized in the first publications on the alarm reaction, and this has been fully confirmed by subsequent investigators. It has also been noted that starvation sensitizes the rat and other species to superimposed stressors such as cold, restraint or trauma. On the other hand, chronic partial starvation produces a singular syndrome of "*pseudohypophsectomy*" which exhibits many of the typical manifestations of stress but is associated with adrenal atrophy. The mechanism of this singular response is still not clear, but a considerable amount of confusion has arisen in the literature by disregard of the essential difference between acute total starvation and chronic under-nutrition.

The frequent combination of *Kwashiorkor* and undernutrition, especially in India, has led to numerous studies on the relationship between these two conditions. It has been suggested that adrenocortical failure to respond adequately to stressors may be a crucial step in the "dysadaptation or breakdown of adaptation resulting in the characteristic biochemical and clinical picture of Kwashiorkor."

Data on *hormonal* changes caused by nutritional factors are comparatively scarce and largely contradictory. It has been claimed that in undernourished children with emotional deprivation, the serum STH levels are usually increased, though the STH

and ACTH response to hypoglycemia is diminished. The STH content of the adenohypophysis decreases during starvation in the rat, and apparently, there is a reduced synthesis and release of this hormone owing to a diminution in the production of STH-releasing factor (SRF). The blood glucagon level decreases during starvation in man just as it does after various other treatments that cause an increased need for glucose. In rats, swimming to exhaustion in cold water causes depletion of brain 5-HT and NEP; similar changes have been observed after exposure to some but not all stressors tested. (The voluminous literature on the effects of malnutrition upon *psychologic reactions, cardiovascular diseases*, and so on should be consulted in the original publications.)

+Other Agents

We have already mentioned the fact that malnutrition sensitizes to the damaging effects of various stressors. This has been shown especially as regards resistance to *cold*, because starvation appears to interfere with thermoregulation. In rats, cold causes considerable proliferation of brown adipose tissue (the so-called hibernating gland). In rabbits, ordinary adipose tissue is used as a readily available source of caloric energy during starvation, whereas brown fat is not as easily accessible. Starvation appears to have a particularly facilitating effect upon the production of gastric ulcers by cold or restraint, and these combinations have therefore extensively been used in studies on experimental "stress ulcers."

Restraint is another stressor to which starvation considerably sensitizes, and as previously mentioned, manifests itself especially in the frequent and severe development of gastroduodenal ulcers. Vitamin B₁₅ (calcium pangamate) allegedly diminishes some characteristic metabolic stress manifestations of restraint in rats.

Resistance to *traumatic* injuries appears to be particularly dependent upon the protein content of the diet.

Electroshock aggravates hypercholesterolemia, hyperlipemia and atherosclerosis in rats kept on a high-fat, high-cholesterol diet. Combativeness upon exposure to electric shock does not seem to be affected by undernutrition in rats.

Among *other stressors* whose dependence upon dietary factors has been the subject of special studies we may mention: infections, hypoxia, crowding, hemorrhage, drugs, circadian variations, and muscular exercise. There is as yet no confirmation of the claim that vitamin C supplements, when given with a standard amount of adrenocortical extract, increase the resistance of adrenalectomized rats to the mild stress of ether anesthesia.

Generalities

(See also our earlier stress monographs, p. xiii)

Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* **17**: 234-248 (1936). 36,032/36

First detailed description of the "alarm reaction" characterized by adrenocortical en-

largement with acute loss of lipids, thymic-colymphatic atrophy and decreased body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for forty-eight hours or more, large doses of atropine, morphine, formaldehyde or EP). Adrenalectomy and, to a lesser extent, hypophysectomy prevent the thymus involution. "The changes caused by a drug when it is given for the

first time will subside later in spite of the continued administration of this drug" but greatly shorten survival. Perhaps the adrenal enlargement, loss of body weight and other manifestations of the alarm reaction enable the organism "to meet critical situations more efficiently."

Selye, H.: "Studies on adaptation." *Endocrinology* **21**: 169-188 (1937).

38,798/37

In rats, "hunger and cold are very active factors in aggravating the effects of alarming stimuli. In fact, cold or any other stimulus which is able to cause an alarm reaction by itself acts in a similar way. Thus it is possible, for instance, to obtain a typical alarm reaction by giving one quarter of the alarming dose of 4 different drugs within 48 hours, although one quarter of the alarming dose of any one of these drugs has no effect by itself."

Mulinos, M. G., Pomerantz, L., Smelser, J., Kurzrok, R.: "Estrus-inhibiting effects of inanition." *Proc. Soc. Exp. Biol. Med.* **40**: 79-83 (1939). A17,221/39

Various agents that cause loss of weight (adrenalectomy, dietary deficiencies, vitamin B₁-avitaminosis, dinitrophenol, thyroid extract) had been shown by others to produce anestrus in the rat. Other potentially toxic treatments (insulin, manganese-free diets, morphine, nicotine) which under the employed experimental conditions did not cause loss of weight also failed to elicit anestrus. The authors' own experiments on partially starved rats "support the conclusion that in the investigations alluded to above, the loss of estrus was either wholly or at least in part due to the concomitant inanition." Since both gonadotropic hormone and estradiol did elicit estrus changes in underfed rats, the cause of the derangement was seen in the malfunction of the pituitary resulting from inanition.

Mulinos, M. G., Pomerantz, L.: "Pseudohypophysectomy. A condition resembling hypophysectomy produced by malnutrition." *J. Nutr.* **19**: 493-504 (1940). A33,348/40

Mulinos, M. G., Pomerantz, L.: "The reproductive organs in malnutrition. Effects of chorionic gonadotropin upon atrophic genitalia of underfed male rats." *Endocrinology* **29**: 267-275 (1941). A36,530/41

Mulinos, M. G., Pomerantz, L.: "Hormonal influences on the weight of the adrenal

in inanition." *Am. J. Physiol.* **132**: 368-374 (1941). A36,788/41

Mulinos, M. G., Pomerantz, L.: "Pituitary replacement therapy in pseudohypophysectomy. Effect of pituitary implants upon organ weights of starved and underfed rats." *Endocrinology* **29**: 558-563 (1941).

A36,729/41

In chronically underfed rats, loss of body weight was accompanied by atrophy of the adrenals, ovaries, spleen, testes, thyroids, hypophysis, thymus, liver and kidneys. Anterior pituitary implants restored the weight of the endocrines. This syndrome of "pseudohypophysectomy" is in sharp contrast to that produced by acute stressors during the alarm reaction.

Mulinos, M. G., Pomerantz, L., Lojkin, M. E.: "Effects of pseudohypophysectomy (underfeeding), starvation, hormones and aging upon the ascorbic acid content of the adrenal glands and liver of the rat." *Endocrinology* **31**: 276-281 (1942). A38,469/42

In chronically underfed rats, the adrenals undergo atrophy as well as a decrease in adrenal ascorbic acid content and concentration. These changes can be corrected by pituitary implants. On the other hand, complete starvation causes an acute increase in the weight and ascorbic acid content of the adrenals. It is concluded that chronic underfeeding causes adenohypophyseal deficiency and adrenocortical changes quite opposite to those characteristic of the alarm reaction; the changes are designated by the authors as the "pseudohypophysectomy" of starvation.

Mitchell, H. H., Edman, M.: *Nutrition and Climatic Stress*, p. 235. Springfield, Ill.: Charles C Thomas, 1951. B65,070/51

Technical discussion of observations on stress caused by cold, heat, high altitude and acceleration in relation to the nutrition of man (more than 750 refs.).

Baker, B. L.: "A comparison of the histological changes induced by experimental hyperadrenocorticalism and inanition." *Recent Prog. Horm. Res.* **7**: 331-373 (1952). B68,657/52

Careful review of the morphologic changes induced in rats by starvation, many of which strikingly resemble those elicited by excess ACTH or glucocorticoids. Yet it is considered unlikely that they are actually due to increased corticoid secretion (81 refs.).

Mitchell, M. L.: "Stress factors and nutri-

tion." *J. Am. Diet. Assoc.* **29**: 753-757 (1953). B79,353/53

Brief review on the roles of stress factors in nutrition.

Galdston, I.: *Beyond the Germ Theory*, p. 182, New York and Minneapolis: Health Education Council, 1954. C1,722/54

Very readable book with major emphasis upon the disease-producing effects of "deprivation stress" in relation to the G.A.S. Special sections on deprivation of food and emotional stimuli.

Jaya Rao, K. S.: "Evolution of kwashiorkor and marasmus." *Lancet* April 20, 1974, pp. 709-711. H85,623/74

Studies on kwashiorkor and marasmus in India show that the two are only different facets of the same disease. "It is suggested that marasmus, characterised by severe growth retardation, but remarkably well-preserved metabolic processes, represents a state of good adaptation to the stress of protein-calorie malnutrition. The response of the adrenal cortex may be crucial for this adaptation, a normal increase in plasma-cortisol helping in adequate mobilisation of muscle protein and in maintenance of metabolic integrity. The failure of the adrenal cortex to respond adequately may represent the crucial step in dysadaptation or breakdown of adaptation, resulting in the characteristic biochemical and clinical picture of kwashiorkor" (25 refs.).

→Hormones

Barchas, J. D., Freedman, D. X.: "Brain amines: response to physiological stress." *Biochem. Pharmacol.* **12**: 1232-1238 (1963).

E29,915/63

In rats, swimming to exhaustion, especially in cold water, caused depletion of brain 5-HT and NEP. Similar changes could not be obtained by having them run in a revolving cage because under the conditions of the experiment the rats soon gave up and just allowed themselves to be dragged. On the other hand, immersion in cold water did reproduce the catecholamine depletion whereas several other stressors (electroshock, starvation, hypoxia, surgery, adrenalectomy) were ineffective in this respect. The response is not dependent upon the pituitary-adrenocortical system since active stressors deplete brain catecholamines even after hypophysectomy, as does LSD. It is noteworthy that drugs that induce a similar change in brain amines produce a unique pattern of central excitation acting on brain mechanisms concerned with metabolic and physiologic temperature regulation. "If the stressors have such a central action, a role for the biogenic amines in central as well as in peripheral

aspects of temperature regulation should be sought."

Friedman, R. C., Reichlin, S.: "Growth hormone content of the pituitary gland of starved rats." *Endocrinology* **76**: 787-788 (1965). F35,443/65

The STH content of the adenohypophysis of rats decreases progressively during starvation for twenty-four to ninety-six hours.

Meites, J., Fiel, N. J.: "Effect of starvation on hypothalamic content of 'somatotropin releasing factor' and pituitary growth hormone content." *Endocrinology* **77**: 455-460 (1965). F49,805/65

In rats, starvation reduces the synthesis and secretion of STH-releasing factor (SRF) by the hypothalamus, which results in a decreased STH discharge from the adenohypophysis.

Aguilar-Parada, E., Eisentraut, A. M., Unger, R. H.: "Effects of starvation on plasma pancreatic glucagon in normal man." *Diabetes* **18**: 717-723 (1969).

H18,441/69

Through the use of relatively specific anti-serum for pancreatic glucagon, it was found that blood levels of the latter rose considerably during starvation in man. Literature is cited showing that insulin, phlorhizin, certain sulfonylurea derivatives, arginine and various other amino acids likewise cause hyperglucagonemia, and apparently the hormone is secreted in excess whenever a glucose need arises (23 refs.).

Krieger, I., Mellinger, R. C.: "Pituitary function in the deprivation syndrome." *J. Pediatr.* **79**: 216-225 (1971). G85,342/71

In children with food and emotional deprivation, fasting serum STH was usually increased but the STH and ACTH response to hypoglycemia was diminished.

Mulinos, M. G., Pomerantz, L., Smelser, J., Kurzrok, R.: "Estrus-inhibiting effects of inanition." *Proc. Soc. Exp. Biol. Med.* **40**: 79-83 (1939).

A17,221/39

Various agents that cause loss of weight (adrenalectomy, dietary deficiencies, vitamin B₁-avitaminosis, dinitrophenol, thyroid extract) had been shown by others to produce anestrus in the rat. Other potentially toxic treatments (insulin, manganese-free diets, morphine, nicotine) which under the employed experimental conditions did not cause loss of weight also failed to elicit anestrus. The authors' own experiments on partially starved rats "support the conclusion that in the investigations alluded to above, the loss of estrus was either wholly or at least in part due to the concomitant inanition." Since both gonadotropic hormone and estradiol did elicit estrus changes in underfed rats, the cause of the derangement was seen in the malfunction of the pituitary resulting from inanition.

Mulinos, M. G., Pomerantz, L.: "Pituitary replacement therapy in pseudohypophysectomy. Effect of pituitary implants upon organ weights of starved and underfed rats." *Endocrinology* **29**: 558-563 (1941).

A36,729/41

In chronically underfed rats, loss of body weight was accompanied by atrophy of the adrenals, ovaries, spleen, testes, thyroid, hypophysis, thymus, liver and kidneys. Anterior pituitary implants restored the weight of the endocrines. This syndrome of "pseudohypophysectomy" is in sharp contrast to that produced by acute stresses during the alarm reaction.

Bajusz, E.: *Nutritional Aspects of Cardiovascular Diseases*, p. 244. London: Crosby Lockwood & Son, 1965.

E5,013/65

Monograph on the influence of diet upon the development of *cardiovascular disease*, with special emphasis on nutritional factors determining predisposition to stress-induced experimental cardiac necroses.

Kim, Y. S., Lambooy, J. P.: "Riboflavin deficiency and gastric ulcer production in the rat: a procedure for the study of susceptibility to stress-induced gastric ulcers." *J. Nutr.* **91**: 183-188 (1967). G45,068/67

Riboflavin deficiency increased the susceptibility of rats to stress-induced (rocking cage) *gastric ulcers*. A comparable degree of general inanition did not have this effect.

Pegelman, S. G., Kanarik, U. K.: "Adaptive responses in guinea pigs under conditions of a prolonged cooling." *Sechenov Physiol. J. U.S.S.R.* **53** No. 10: 1212-1217 (1967).

J13,141/67

Exposure of guinea pigs to cold causes marked *adrenal hypertrophy* and ascorbic acid depletion with eosinopenia. Pretreatment with ascorbic acid reverses the *eosinophil response* and virtually blocks loss of ascorbic acid from the adrenals.

Hocking, F.: "Extreme environmental stress and its significance for psychopathology." *Am. J. Psychother.* **24**: 4-26 (1970).

G72,373/70

Review on "some of the immediate and possible long-term [*psychologic*] effects of a number of situations involving severe to extreme stress, including semistarvation, sensory deprivation, natural disasters, military combat, concentration camps, Russian labor camps, and nuclear bombings" (78 refs.).

+Temperature Variations. Horst, K., Mendel, L. B., Benedict, F. G.: "The metabolism of the albino rat during prolonged fasting at two different environmental temperatures." *J. Nutr.* **3**: 177-200 (1930).

6,639/30

Rats fasting at 26°C lived an average of 16.5 days and lost 49 percent of their initial body weight, whereas those fasting at 16°C survived an average of eleven days and lost 44 percent of their weight.

Leduc, J.: "Catecholamine production and release in exposure and acclimation to cold." *Acta Physiol. Scand.* **53** Supp. 183: 1-101 (1961). D42,829/61

Review of personal observations indicating that "warm- and cold-acclimated rats could

not withstand prolonged exposure to cold after restriction of food. Their catecholamine excretion rapidly attained maximal values and animals died in hypothermia. The same happened with warm-acclimated rats whose insulation has been reduced by removal of the fur. Cold-acclimated clipped rats survived in the cold, but their catecholamine response was much more intense than that of intact cold-acclimated animals." Allegedly these experiments suggest that acclimation to cold is limited by the body's finite capacity to produce catecholamines and thereby maintain thermal balance. EP is considered to be a defense hormone against cold.

Boulouard, R.: "Effects of cold and starvation on adrenocortical activity of rats." *Fed. Proc.* **22**: 750-754 (1963).

E20,995/63

In rats, starvation brings about a very significant increase in plasma corticosterone that is even more considerable in the event of simultaneous exposure to cold. The relationship between these findings and Porter-Silber chromogens is discussed. The strongest adrenocortical response occurs during the first few days of exposure to cold; secretion diminishes later despite the continued maintenance of adrenocortical hypertrophy.

Heim, T., Kellermayer, M.: "The effect of environmental temperature on brown and white adipose tissue in the starving newborn rabbit." *Acta Physiol. Acad. Sci. Hung.* **31**: 339-346 (1967). G50,688/67

The effect of stress upon fat mobilization was studied in newborn rabbits starved to death at different environmental temperatures. "Brown fat is mobilized in response to cold but not during starvation in a thermoneutral environment, whereas white fat apparently serves as a general metabolic reserve and is used during starvation both in the absence and the presence of a cold-induced increase in heat production."

Buchel, L., Gallaire, D.: "Ulcères de contrainte chez le rat. I. Influence, sur la fréquence des ulcères, du jeûne et de la température de l'environnement associés à des immobilisations de durées variables" (Restraint ulcers in the rat. I. Influence of fasting and environmental temperature associated with restraint of variable duration on the incidence of restraint ulcers). *Arch. Sci. Physiol.* **21**: 527-536 (1967). G53,615/67

In rats, twenty-four hours of fasting increases the incidence of gastric ulcers pro-

duced by subsequent restraint. Concurrent exposure to cold further sensitizes the stomach to the development of these stress ulcers.

Hale, H. B., Mefferd, R. B. Jr.: "Influence of chronic heat exposure and prolonged food deprivation on excretion of magnesium, phosphorus, calcium, H^+ and ketones." *Aerospace Med.* **39**: 919-926 (1968).

G63,858/68

Description of the metabolic changes produced in rats by "interplay of two stressors, chronic heat exposure and prolonged food deprivation."

Brooke, O. G., Harris, M., Salvosa, C. B.: "The response of malnourished babies to cold." *J. Physiol. (Lond.)* **233**: 75-91 (1973).

J5,659/73

Malnourished Jamaican children failed to raise their heat production and had decreased rectal temperature when environmental temperature was reduced from 28 to 25° C.

+Restraint. Frisone, J. D., Essman, W. B.: "Stress-induced gastric lesions in mice." *Psychol. Rep.* **16**: 941-946 (1965).

G41,731/65

"Immobilization-induced stress contributed little more to the incidence and severity of gastric lesions in mice than did food deprivation alone." Apparently, the gastric ulcers produced by immobilization are essentially due to fasting.

Buchel, L., Gallaire, D.: "Influence de la température ambiante sur la production d'ulcères de contrainte chez le rat" (Influence of surrounding temperature on the production of restraint ulcers in rats). *C.R. Soc. Biol. (Paris)* **160**: 1817-1820 (1966).

F78,016/66

A decrease of the surrounding temperature from 24 to 14° C facilitates the production of restraint ulcers in rats, whether or not they are previously exposed to twenty-four hours of fasting. The latter accelerates the development of such restraint ulcers. On the other hand, body temperature does not appear to be the only important factor since rats kept at warm temperatures (28-32° C) still show gastric erosions, whereas treatment with phenobarbital or chloral hydrate during restraint aggravates the hypothermia and yet diminishes ulcer frequency.

Robert, A., Phillips, J. P., Nezamis, J. E.: "Production, by restraint, of gastric ulcers and of hydrothorax in the rat." *Gastroenterology* **51**: 75-81 (1966).

G40,473/66

In rats, restraint produced gastric ulcers and hydrothorax within four to six hours. Overnight fasting prevented the hydrothorax and reduced gastric ulcerations (contrary to previous reports). Restraint ulcers and hydrothorax "were also inhibited by crowding of the animals, a rise in ambient temperature, or administration of prednisolone."

Rasche, R., Butterfield, W. C.: "Vitamin A pretreatment of stress ulcers in rats." *Arch. Surg.* **106**: 320-321 (1973).

J641/73

Studies on rats receiving 10,000 international units of vitamin A prior to an eight-hour period of immobilization in a wire gauze device suggest that this vitamin "exerts a negligible, if any, protective effect on the occurrence of gastric ulceration."

Khomulo, P. S., Mytareva, L. V., Zakrinichnaya, G. A.: "Oxygen and glucose utilization by aortic tissue with administration of cholesterol and nervous system stress." *Kardiologija* **13** No. 1: 116-120 (1973) (Russian).

H80,123/73

In rats, vitamin B₁₅ (calcium pangamate) allegedly diminishes certain metabolic changes produced by restraint.

Sibilly, A., Krivošič, I., Foucher, G., Fresnel, P. L., Bouteiller, P.: "Prévention locale de l'ulcère gastrique expérimental. (Etude préliminaire)" (Topical prevention of experimental gastric ulcer. [Preliminary study]). *J. Chir. (Paris)* **106**: 521-534 (1973).

J10,151/73

In rats, the stress ulcers produced by restraint are aggravated by fasting and prevented by oral administration of glucose or aluminum gel. Neutralization of the gastric acid does not seem to be decisive since aluminum gel protects less than hypertonic glucose; perhaps the latter helps to maintain cell metabolism and the gastric barrier.

+Other Stressors. Lazovik, A. D., Patton, R. A.: "The relative effectiveness of *auditory stimulation* and *motivational stress* in precipitating convulsions associated with magnesium deficiency." *J. Comp. Physiol. Psychol.* **40**: 191-202 (1947).

B26,573/47

Malmros, H.: "The relation of nutrition to health. A statistical study of the effect of the war-time on arteriosclerosis, cardiosclerosis, tuberculosis and diabetes." *Acta Med. Scand.* **138**: 137-153 (1950).

B60,638/50

During the postwar years, starvation increased the incidence of tuberculosis in Germany.

Quaife, M. L., Harris, P. L.: "Relation of vitamin E to acute physiological stress." *Proc. Soc. Expt. Biol. Med.* **78**: 188-191 (1951).

B63,658/51

The vitamin E content of the diet had no significant effect upon the adrenal ascorbic acid concentration of rats exposed to stressors (*EP* and *cold*). Furthermore, stress was not associated with any conspicuous change in tissue vitamin E levels.

Ryer, R., Grossman, M. I., Friedemann, T. E., Best, W. R., Consolazio, C. F., Kuhl, W. J., Insull, W. Jr., Hatch, F. T.: "The effect of vitamin supplementation on soldiers residing in a cold environment. Part II. Psychological, biochemical, and other measurements." *J. Clin. Nutr.* **2**: 179-194 (1954).

C8,720/54

In soldiers receiving large supplements of vitamin B complex and ascorbic acid, exposure to *cold* caused biochemical changes characteristic of stress that did not differ significantly from those in the controls. The higher incidence of eosinopenia during forced marches in the supplemented group was statistically significant.

Myasnikov, A. L.: "Influence of some factors on development of experimental cholesterol atherosclerosis." *Circulation* **17**: 99-113 (1958).

C68,103/58

In rabbits, the development of cholesterol atherosclerosis can be delayed by such stressors as *hypoxia* or *physical exercise*. "These effects may be considered useful to some degree in preventing atherosclerosis in man as well."

Uhley, H. N., Friedman, M.: "Blood lipids, clotting and coronary atherosclerosis in rats exposed to a particular form of stress." *Am. J. Physiol.* **197**: 396-398 (1959).

C73,763/59

In rats kept on a high-fat, high-cholesterol diet in a cage that periodically delivered *electric shocks*, unusually pronounced hypercholesterolemia, hyperlipemia and coronary atherosclerosis developed at the end of ten months.

Bhagat, B., Lockett, M. F.: "The failure of the adrenals to respond to cold stress during thiamine deficiency." *J. Endocrinol.* **23**: 237-241 (1961).

D16,943/61

"The adrenal glands of thiamine-deficient mice weighed more than those of normal mice and responded to *adrenocorticotropic hormone*, but not to *cold stress*, by further hypertrophy."

Hodges, J. R., Vernikos-Danellis, J.: "Pitu-

itary and blood corticotrophin changes in adrenalectomized rats maintained on physiological doses of corticosteroids." *Acta Endocrinol.* **39**: 79-86 (1962). D16,314/62

In adrenalectomized rats, ACTH discharge after mild stress (*ether*) was greater than in the controls. This hyperexcitability of the pituitary was not diminished by corticoids alone, but was considerably reduced by adrenocortical extracts plus ascorbic acid. Perhaps corticoids control the rate of ACTH synthesis, but other factors including ascorbic acid regulate pituitary responsiveness to stress-induced ACTH secretion.

Cuthbertson, D. P.: "Physical injury and its effects on protein metabolism." In: Munro, H. N. and Allison, J. B., *Mammalian Protein Metabolism*, Vol. 2, pp. 373-414. New York and London: Academic Press, 1964.

G79,175/64

Review on the effect of stress upon protein metabolism. In man, protein loss within ten days of *physical injury* may amount to about 12 percent of the total body protein. In general, there is a catabolic loss during the first ten days and a maximum at about the third day with a secondary peak on the eighth day. With regard to dietary treatment, most observers hold that "during the first few days following the injury in the previously adequately nourished person it is probably unwise to push the intake of a well-balanced diet beyond appetite as this may fail during this early postinjury phase in severe injuries. Further, kidney function may not be normal for a day or two. Thereafter the patient should be encouraged, but not forced, to take as much as he can of a well-balanced diet, relatively rich in protein."

Essman, W. B., Frisone, J. D.: "Isolation-induced facilitation of gastric ulcerogenesis in mice." *J. Psychosom. Res.* **10**: 183-188 (1966).

G41,114/66

Isolation facilitates the gastric ulcerogenesis induced by fasting in mice. "The data suggest that isolation contributes to food intake and food disposition and differences in the duration of aggregation or isolation and resulting ulcer development may be accounted for in terms of: (1) differences in motor activity, or (2) age [of the mice at the time] of change in population density."

Kies, C., Fox, H. M., Williams, E. R.: "Time, stress, quality, and quantity as factors in the nonspecific nitrogen supplementation of corn protein for adult men." *J. Nutr.* **93**: 377-385 (1967).

H6,953/67

In man, nitrogen retention after the stress of *hemorrhage* can be improved by a nitrogen-supplemented corn diet, but a similarly supplemented milk diet is even more effective.

Freiman, M., Seifter, E., Connerton, C., Levenson, S. M.: "Vitamin A deficiency and surgical stress." *Surg. Forum* **20**: 81-82 (1970). H64,565/70

It is suggested that "impaired glucose mobilization may be associated with the reduced ability of the vitamin A deficient rat to survive *surgical stress*."

Langlois, P., Williams, H. B., Gurd, F. N.: "Effect of an elemental diet on mortality rates and gastrointestinal lesions in experimental burns." *J. Trauma* **12**: 771-777 (1972). G94,742/72

Rats fed an "elemental diet" in which amino acids replaced all the protein showed improved survival and diminished gastrointestinal lesions after *burns*.

Hartzell, W. G., Newberry, P. D.: "Effect of fasting on tolerance to moderate hypoxia." *Aerospace Med.* **43**: 821-826 (1972).

H80,194/72

In man, "acute fasting significantly increases the orthostatic, hypotensive response to moderate *hypoxia*. This synergistic effect was sufficient to induce a syncopal attack in one normal individual during stress by moderate hypoxia while fasting, and this subject's recovery was delayed for more than 20 minutes after return to breathing room air."

Sakai, S.: "Effect of protein content of rat diet on amount of corticosterone in tooth extraction." *Folia Pharmacol. Jap.* **68**: 66-72 (1972) (Japanese). H79,322/72

In rats on a low-protein diet the adrenals are comparatively small but show a pronounced increase in size during the stress of *tooth extraction*, which is ineffective in this respect in controls given normal amounts of protein.

Creer, T. L.: "Hunger and thirst in shock-induced aggression." *Behav. Biol.* **8**: 433-437 (1973). H80,353/73

Hunger and *thirst* did not affect the mean of fighting among rats who initially showed a considerable rate of combativeness after electric shocks to the feet. Fasting likewise failed to alter the frequency of fighting in low-aggression rats but water deprivation increased it.

Paisey, R. B., Angers, M., Frenk, S.: "Plasma cortisol levels in malnourished children with and without superimposed acute

stress." *Arch. Dis. Child.* **48**: 714-716 (1973). J6,618/73

Plasma cortisol levels in malnourished children with marasmus or kwashiorkor were essentially normal unless superimposed stress (*infection, hypoglycemia, acidosis*) caused a rise.

Hamid, J., Sayeed, A., McFarlane, H.: "The effect of 1-(o-chlorophenyl)-1-(p-chlorophenyl)-2,2-dichloroethane (o,p'-DDD) on the immune response in malnutrition." *Br. J. Exp. Pathol.* **55**: 94-100 (1974).

H86,118/74

In rats, *o,p'-DDD* caused loss of body weight as well as involution of the thymus, spleen and adrenals. In malnourished rats, adrenal atrophy was particularly marked and was associated with diminution of plasma corticoids and a decrease in the impairment of the immune response normally occasioned by this drug.

Pintar, K., Schulte, W. J., Barboriak, J. J.: "Histologic study of gastric lesions in food-restricted rats." *Proc. Soc. Exp. Biol. Med.* **145**: 1353-1358 (1974). H86,412/74

"Rats limited to food intake of 1 hr a day and allowed to run in an *activity wheel* developed gastric lesions which, on histologic examination, resembled human stress ulcers."

Bruckdorfer, K. R., Kang, S. S., Khan, I. H., Bourne, A. R., Yudkin, J.: "Diurnal changes in the concentrations of plasma lipids, sugars, insulin and corticosterone in rats fed diets containing various carbohydrates." *Horm. Metab. Res.* **6**: 99-106 (1974).

H86,042/74

Menguy, R., Masters, Y. F.: "Mechanism of stress ulcer. IV. Influence of fasting on the tolerance of gastric mucosal energy metabolism to ischemia and on the incidence of stress ulceration." *Gastroenterology* **66**: 1177-1186 (1974). J13,618/74

Fasting greatly sensitizes the gastric mucosa of the rabbit to the induction of stress ulcers by *hemorrhage*. These and many other observations suggest that "stress ulceration complicating hemorrhagic shock results from a gastric mucosal energy deficit due to shock-induced mucosal ischemia."

Wells, A., Jones, A., Williams, M., Geist, C. R.: "Noise, vitamin A deficiency, and emotional behavior in rats." *Percept. Mot. Skills* **38**: 392-394 (1974). J17,474/74

In rats, aversive stimulation (*noise*) appears to have a greater effect during food deprivation or vitamin A deficiency than otherwise.

*PHYSICAL AGENTS**Temperature Variations (including Frostbite)*

Exposure to cold was one of the first stressors used in animal experiments to prove the nonspecificity of agents capable of eliciting an alarm reaction with the typical thymicolumphatic involution, adrenal enlargement and gastrointestinal ulcers. Many review articles summarize the response of animals and man to short- or long-term exposure to cold, including adaptation to this stressor and "cross sensitization," in which adaptation to cold increases sensitivity to subsequent exposure to heat and vice versa. The relationship between the effects of cold upon nonhibernating animals, natural hibernation and "artificial hibernation" induced by cooling after pretreatment with various drugs, has likewise been the subject of extensive studies which yielded widely differing results.

The special problems arising from temperature variations in different climates, such as, the tropics, the Arctic, and Antarctic regions are discussed at greater length in the sections, Climate, Environment, and Biorhythms, and the section on Occupations, although there the role of temperature variations as such is difficult to distinguish from associated factors, such as the loneliness of the polar regions, or the noise, vibrations and muscular fatigue in overheated factories.

We will consider the effects of frostbite conjointly with systemic undercooling since the two are often combined, whereas burns, which usually occur as a consequence of local heat application at normal surrounding temperatures, will be discussed separately in the next section.

→**Morphology.** Even localized frostbite, from cooling the tails of rats, produces typical G.A.S. changes (for example, loss of secretory granules from the adrenal cortex and medulla) as well as a discharge of thyroid colloid. However, the latter is usually considered to be a specific effect of systemic heat loss, against which increased thyroid hormone secretion can protect by raising the BMR. Of course, systemic exposure to cold is even more effective as a stressor in some species in that it produces eosinopenia, lymphopenia and the discharge of histologically visible secretory granules from the adrenal cortex and medulla. Exposure to heat acts similarly but for hitherto unexplained reasons, it appears to be much less effective in this respect within the temperatures compatible with survival.

Upon chronic exposure to extremes of temperature, experimental animals go through the three characteristic stages of the G.A.S. and eventually exhibit pronounced loss of body weight and gonadal atrophy.

→**Hormones.** The endocrine changes produced by heat or cold are very similar to those elicited by other stressors, except for the characteristic increase in TTH and thyroid hormone secretion, which is a specific compensatory mechanism for heat loss during exposure to cold.

In rats, graded doses of thyroxine increase adrenal weight as a consequence of a rise in ACTH secretion. This is accompanied by an increase in total plasma corticosterone without significant alteration in the unbound fraction of the hormone. Presumably, only free corticosterone is responsible for the feedback inhibition, and the

binding capacity of transcartin is stimulated only by thyroxine, which can thus adjust corticoid production to thyroid activity at different temperatures.

In man, intense muscular work in hot environments increases the corticoid excretion in sweat even more than in urine. Allegedly, under these conditions a significant fraction of the total corticoid elimination is accounted for in sweat.

It has also been claimed that aldosterone excretion is particularly augmented in man exposed to heat, perhaps because this mineralocorticoid plays an important defensive role in protecting against heat-induced electrolyte anomalies.

Catecholamines have been thought to play a specific protective role against cold, and the finite capacity of the body to produce them may sometimes be the decisive factor in determining the limits of cold resistance. The excretion of NEP is more markedly augmented by cold than that of EP. Enzymologic studies suggest that the increase of NEP biosynthesis during cold is due to excess dopamine formation.

The urinary elimination of corticoids allegedly rose while that of EP and NEP remained unchanged in men exposed to the cold of Antarctic regions.

Very acute cold, sufficient to lower rectal temperatures and increase plasma cortisol and catecholamine excretion, does not change the TTH or thyroid hormone levels of the blood presumably because, in man, relatively severe but acute cold of a few hours duration acts mainly as a physical and emotional stressor, without effectively mobilizing heat regulation through the thyroid.

In adults, allegedly, even short-term exposure to cold suffices to raise plasma STH, whereas this is not the case in full-term or premature babies whose plasma STH, TTH, insulin, and glucagon levels are not significantly affected by cold.

In unacclimatized subjects, exposure to heat for two hours increases plasma cortisol and corticosterone concentrations as well as the urinary elimination of 17-OHCS. Studies with radiocortisol suggest that most of the corticoid rise is due to increased secretion, but this is accompanied by accelerated blood clearance in hot environments. In obese men, exposure to hot air for one hour after an overnight fast elevates body temperature and increases plasma STH and FFA levels without causing significant changes in plasma cortisol, thyroxine or glucose.

→**Metabolites.** In adult men exposed to cold of an intensity sufficient to raise plasma cortisol and diminish body temperature, the total plasma amino acid content is said to be unaffected, but tryptophane and tyrosine levels are lowered, and the excretion of two major tryptophane metabolites (kynurenic and xanthurenic acids) suggests an increase in hepatic tryptophane oxygenase activity. This may make the two amino acids more readily available for protein, hormone and biogenic amine synthesis during stress.

In mice, exposure to cold increases hepatic tryptophane oxygenase and tyrosine amino transferase activity. However, there are no strict correlations between these changes and the reduced plasma tryptophane, tyrosine and brain NEP or 5-HT. Apparently, under these conditions, alternative pathways can maintain homeostasis.

Cold also appears to increase cholesterol-7α-hydroxylase activity in the liver as well as the phosphatidyl glycerol and FFA levels in plasma.

→**Varia.** Fibrinolytic activity is increased in both whole blood and plasma in man exposed to heat. During and after a sauna bath, 17-OHCS excretion is raised in normal

but not, or at least much less, in allergic people, although the initial values are essentially the same in both groups.

The EEG changes noted in men kept in water of varying temperatures suggest that the arousal level is not determined exclusively by the ambient temperature.

In sheep, fertility is diminished by exposure to heat, but the nonspecificity of this response has not been proven.

+Restraint. There is unanimity among various authors on the fact that cold increases sensitivity to the stressor effect of restraint, and particularly enhances the production of stress ulcers. In fact, combined treatment with cold and restraint has been commonly used as a standard technique for the induction of such lesions. Heat tends to have an opposite effect, but only if it is of moderate intensity.

In rats, restraint during the active phase of their circadian cycle is particularly effective in producing gastric ulcers, and of course, cold augments wakefulness which may be a factor of pathogenic importance.

In guinea pigs overheated up to twenty-one days, there appears to be no significant rise in the normal plasma levels of corticoids, but the corticoid discharge during restraint is reduced. Since they continue to respond normally to ACTH, their insensitivity is attributed to decreased ACTH production.

Antiadrenergic drugs diminish cold-induced gastric ulcers in the rat, suggesting that the increased turnover of NEP may be causally related to their development. Yet, 6-hydroxydopamine-induced "chemical sympathectomy" raises cold resistance in this species.

The muscle relaxant effect of zoxazolamine is enhanced by restraint plus cold in the rat, presumably owing primarily to the increased sensitivity of the nervous system, and perhaps only secondarily to augmented zoxazolamine metabolism during stress.

+Genetics. Somewhat unexpectedly, it has been claimed that both hibernating and nonhibernating Syrian hamsters exhibit no enlargement or other morphologic evidence of adrenal hyperactivity when exposed to cold. Yet, some investigators have stated that the hamster adrenal is sensitive to other stressors and shows distinct histologic changes in the adrenal medulla and cortex during hibernation, upon awakening from hibernation, and during "anesthesia" induced by cold.

In piglets, cold or starvation causes typical G.A.S. changes in the adrenal as well as hypoglycemia and eosinopenia. Certain strains of pigs are particularly stress sensitive.

Female sheep are more resistant to cold than males, but daily "cold shocks" reduce cold resistance and inhibit acclimatization in females though not in males.

The Somali donkey is especially resistant to the stress of heat and dehydration.

+Drugs. In rats, large doses of reserpine—like previous prolonged exposure to cold—decrease the ACTH content of the adenohypophysis sufficiently to prevent a detectable discharge in the response to other stressors. Reserpine reduces body heat much more at low than at high environmental temperatures, presumably by decreasing heat production rather than by increasing heat loss. In rats, chlorpromazine, reserpine and ascorbic acid only slightly inhibit the loss of adrenal ascorbic acid elicited by exposure to heat. In pigs, chlorpromazine diminishes pituitary-adrenocortical hormone discharge and increases the survival rate at 40°C.

Disulfiram, a potent dopamine hydroxylase inhibitor, greatly accentuates the loss

of cardiac NEP in rats exposed to cold, presumably because utilization of NEP is increased at low temperatures. This becomes particularly evident when repletion by biosynthesis is blocked. In rats, cold raises the urinary excretion of NEP, with a concurrent increase in thyroid activity. If cold-acclimated rats are given the antithyroid drug methimazole, the excretion of free EP and NEP doubles, presumably as a result of an effort to compensate for the decreased metabolic activity necessary for heat production.

The stress ulcers elicited in the rat by immersion in cold water can be prevented by atropine and other anticholinergic drugs, whereas reserpine, phenylbutazone and desoxy-2-glucose augment their incidence.

Most α -adrenergic-blocking agents (as well as the depletion of endogenous monoamines by reserpine and tetrabenazine) aggravate, while β -adrenergic-blocking agents inhibit, the production of stress ulcers in rats restrained while immersed in cold water. Fusaric acid, a potent dopamine- β -hydroxylase inhibitor, exerts an antiulcerogenic effect under similar conditions, presumably because of a decrease in the release of NEP from the CNS.

+Trauma. Cold diminishes, whereas moderate heat of a reasonable intensity increases, resistance to the stressor effect of diverse types of trauma in various species.

+Age. Adaptation to cold is less readily acquired by old than by young mice. In contradiction to earlier reports, it has been shown that the pituitary-adrenocortical mechanism is responsive to various stressors, including heat, in neonatal rats, as indicated by the rise in plasma corticosterone, although adrenal ascorbic acid depletion appears to be subnormal.

In premature babies exposed to cold, urinary NEP excretion drops but EP elimination is normal. Possibly, in neonates, cold rapidly depletes the NEP stores and thereby interferes with chemical thermogenesis.

+Diet. The extensive studies on the effect of various diets upon resistance to temperature fluctuations did not lead to any clearcut results which would permit us to formulate an optimal diet for defense against thermal stressors. However, fasting undoubtedly diminishes cold resistance in various species and increases corticoid production beyond the levels elicited by cold or starvation alone.

Malnourished Jamaican children failed to raise heat production and developed hypothermia easily when the surrounding temperature was diminished.

+Ionizing Rays. Allegedly, cold protects the rat against total body irradiation, whereas the latter has a detrimental effect on survival upon subsequent exposure to cold.

+Varia. The literature contains data on the effects of variations in ambient temperature upon resistance to many other stressors, but these observations are too numerous, and the data on each one too scarce to warrant detailed discussion here. Hence, the reader is referred to the corresponding abstract section. There he will find data on the effects of external temperature upon resistance to burns, electric shocks, hypoxia, diving, muscular work, gravitational forces, infections, the demands made by aerospace performance, the menstrual cycle and so on.

Temperature, including Frostbite

Generalities. Selye, H.: "Studies on adaptation." *Endocrinology* **21**: 169-188 (1937). C38,798/37

In rats, "hunger and cold are very active factors in aggravating the effects of alarming stimuli. In fact, cold or any other stimulus which is able to cause an alarm reaction by itself acts in a similar way. Thus, it is possible, for instance, to obtain a typical alarm reaction by giving one quarter of the alarming dose of 4 different drugs within 48 hours, although one quarter of the alarming dose of any one of these drugs has no effect by itself."

→Morphology. Zenow, Z. I.: "Über Veränderungen im endokrinen System bei experimenteller örtlicher Erfrierung" (Changes in

the endocrine system caused by experimental localized frostbite). *Virchows Arch. [Pathol. Anat.]* **312**: 486-500 (1944). B28,100/44

In rats, localized frostbite from cooling the tails causes typical G.A.S. changes with an initial depletion and subsequent increase in adrenocortical lipids, discharge of medullary EP and loss of colloid from thyroid.

Elmadjian, F., Pincus, G.: "The adrenal cortex and the lymphocytopenia of stress." *Endocrinology* **37**: 47-49 (1945).

B366/45

In mice, both restraint and exposure to cold produce a typical stress lymphopenia.

Pincus, G., Elmadjian, F.: "The lymphocyte response to heat stress in normal and psychotic subjects." *J. Clin. Endocrinol.* **6**: 295-300 (1946). B1,243/46

Normal men exposed to 40.5-44.0° C at 85 to 95 percent relative humidity exhibited marked "stress lymphocytopenia" attributed to increased corticoid secretion. "With the short-time stress employed here it is entirely likely that we are dealing with the first stage of the adaptation syndrome which involves adrenocortical hypersecretion as the result of the pituitary stimulation." By contrast, twenty out of twenty-one psychotic (mostly schizophrenic) subjects exhibited a rise in blood lymphocytes after heat exposure.

Robinson, F. B., Yoffey, J. M.: "Histochemical changes produced by cold and adrenaline in the suprarenal cortex of the adult male rat." *J. Anat.* **84**: 32-37 (1950).

B48,448/50

In rats, intraperitoneal EP or exposure to cold causes cholesterol depletion from the zona reticularis and inner fasciculata of the adrenal cortex within five minutes. The gland returns to normal after three days. "The 3 stages of Selye's adaptation syndrome can be readily demonstrated by: (a) varying the length of time an animal is exposed to cold, and (b) giving repeated injections of adrenaline over long periods."

Louch, C., Meyer, R. K., Emlen, J. T.: "Effect of stress on diurnal fluctuations in eosinophils of the laboratory mouse." *Proc. Soc. Exp. Biol. Med.* **82**: 668-671 (1953).

B82,222/53

In mice, there are pronounced circadian variations in eosinophil counts, with peaks during the day and drops during the night, presumably owing to the characteristic nocturnal activity of this species. Exposure to cold decreases the eosinophil count but does

not eliminate the circadian fluctuations. Presumably, nocturnal activity in these experiments acts as a secondary stress superimposed upon the sustained stress of exposure to cold, and the adrenal gland "is capable of responding further to the daily stress of nocturnal activity."

Vašku, J.: "Die Beeinflussung der experimentellen diphtherischen Intoxikation durch den künstlichen Winterschlaf" (The influence of artificial hibernation on experimental diphtheria intoxication). *Z. Gesamt. Inn. Med.* **16**: 885-894 (1961).

D80,395/61

Hibernation did not protect guinea pigs against the adrenal changes elicited by diphtheria toxins but it did increase their sensitivity as indicated by a rise in mortality. The "artificial hibernation" (drugs plus cold) used in these experiments acted as a stressor.

Ouellette, R., Perrault, H. J., Dugal, L. P.: "Effet du froid sur le testicule endocrinien: chronologie des événements" (Effect of cold on the endocrine testis: chronology of events). *Rev. Can. Biol.* **24**: 7-21 (1965).

F42,194/65

In male rats, "a time study of the response of the sexual accessories reveals the succession of events as distinct phases related to the duration of the stress and reminiscent of the three stages of the General Adaptation Syndrome."

Skinner, J. D., Louw, G. N.: "Heat stress and spermatogenesis in Bos indicus and Bos taurus cattle." *J. Appl. Physiol.* **21**: 1784-1790 (1966).

G42,859/66

Even short-term exposure of bulls to "heat stress" can adversely affect spermatogenesis and fertility. [Since heat is known to have a specific damaging effect upon the testis, it remains to be shown that this is a non-specific or stress action (H.S.).]

Ambud, L., Agid, R.: "Cold-induced fatty liver and hypothermia in a hibernator, the garden dormouse (*Eliomys quercinus* L.)." *Arzneim. Forsch.* **24**: 967 (1974).

→**Hormones.** Nichols, J., Miller, A. T. Jr.: "Excretion of adrenal corticoids in the sweat." *Proc. Soc. Exp. Biol. Med.* **69**: 448-449 (1948).

B28,608/48

In man, exposure to heat and intense muscular exercise increase the rate of corticoid excretion in sweat more than in urine. Hence, "it is a reasonable assumption that

it indicates an activation of the adrenal cortex in response to the stresses of heat and strenuous exertion. Our results also emphasize the fact that in stresses associated with sweating, a significant fraction of the total corticoid excretion is accounted for in the sweat."

Hellmann, K., Collins, K. J., Gray, C. H., Jones, R. M., Lunnon, J. B., Weiner, J. S.: "The excretion of urinary adrenocortical steroids during heat stress." *J. Endocrinol.* **14**: 209-216 (1956).

C25,981/56

In men exposed to heat, "while there was no significant change in the excretion of 17-hydroxycorticoids, cortisone and cortisol or of tetrahydrocortisone and tetrahydrocortisol, there was a significant increase in the output of aldosterone."

Egdahl, R. H., Richards, J. B.: "Effect of extreme cold exposure on adrenocortical function in the unanesthetized dog." *Am. J. Physiol.* **185**: 239-242 (1956).

D97,431/56

In dogs with polyethylene cannulas in the right lumboadrenal vein, exposure to cold or heat caused an increase in the 17-OHCS content of the collected blood similar to that produced by intravenous ACTH.

Robinson, K. W., MacFarlane, W. V.: "The influence of environmental temperature on the level of plasma antidiuretic substances in the rat." *Aust. J. Biol. Sci.* **9**: 130-138 (1956).

J12,293/56

C48,916/58

In both hydrated and dehydrated guinea pigs, exposure to cold produced a "normal stress response" as indicated by the rise in urinary corticoid excretion. The vasopressor activity of the hypothalamus and posterior pituitary was markedly diminished by dehydration. "Apparently, conditions which induce alterations in mobilization of the antidiuretic hormone do not necessarily induce parallel alterations in the secretion of ACTH in response to stress."

Knigge, K. M.: "Neuroendocrine mechanisms influencing ACTH and TSH secretion and their role in cold acclimation." *Fed. Proc.* **19**: 45-51 (1960) (127 refs.).

C97,819/60

Leduc, J.: "Catecholamine production and release in exposure and acclimation to cold."

Acta Physiol. Scand. **53** Supp. 183: 1-101 (1961). D42,829/61

Review of personal observations indicating that "warm- and cold-acclimated rats could not withstand prolonged exposure to cold after restriction of food. Their catecholamine excretion rapidly attained maximal values and animals died in hypothermia. The same happened with warm-acclimated rats whose insulation had been reduced by removal of the fur. Cold-acclimated clipped rats survived in the cold, but their catecholamine response was much more intense than that of intact cold-acclimated animals." These experiments suggest that acclimation to cold is limited by the finite capacity of the body to produce catecholamines and thereby maintain thermal balance. EP is considered to be a defense hormone against cold.

Gwóździak, B.: "The effect of thermal stress on the level of 17-hydroxycorticosteroids in the blood serum of man." *Endokrinol. Pol.* **13**: 275-286 (1962) (Polish).

Frommel, E., Fleury, C., Ledebur, I. von, Beguin, M.: "On the differential mobilisation of adrenalin and cortisone in the progress of stress under hypothermic conditions of external cause and of vaccine fever." *Med. Exp.* **6**: 261-264 (1962). D27,769/62

In guinea pigs, hypothermia "due to refrigeration, mobilizes adrenalin with an ephemeral action and brief duration, whereas vaccine fever stimulates the hormones of the adrenal cortex, possessing a slower and more lasting effect."

Euler, U. S. von: "Quantitation of stress by catecholamine analysis." *Clin. Pharmacol. Ther.* **5**: 398-404 (1964). G18,238/64

Review of the literature and personal observations on man suggest that "gravitational stress and exposure to cold are mainly associated with an increase in the norepinephrine excretion, indicating the importance of this hormone in circulatory and temperature controlling homeostatic mechanisms. Mental stress involving exhilarating or aggressive reactions is also associated with an increase in the norepinephrine excretion. The types of emotional stress which are mainly characterized by apprehension, anxiety, pain, or general discomfort are regularly accompanied by an increase in the epinephrine excretion." Special sections are devoted to catecholamine

elimination associated with flying, mental work and exposure to cold.

Chowers, I., Hammel, H. T., Eisenman, J., Abrams, R. M., McCann, S. M.: "Comparison of effect of environmental and pre-optic heating and pyrogen on plasma cortisol." *Am. J. Physiol.* **210**: 606-610 (1966). F62,277/66

Kotby, S., Johnson, H. D.: "Rat adrenal cortical activity during exposure to a high (34°) ambient temperature." *Life Sci.* **6**: 1121-1132 (1967). G47,329/67

In rats, after exposure to high surrounding temperatures, "the increase in plasma corticosterone, a calorigenic hormone, may serve as a precursor for increased aldosterone production during acclimation to heat."

Sundberg, M., Kotovirta, M.-L., Pesola, E.-L.: "Effect of the Finnish sauna-bath on the urinary excretion of 17-OH-corticosteroids and blood eosinophil count in allergic and healthy persons." *Acta Allergol. (Kbh.)* **23**: 232-239 (1968). G61,502/68

Urinary 17-OHCS elimination was essentially the same in allergic and normal individuals. "During the sauna day and 24 hours after the sauna bath the healthy subjects showed a statistically significant increase in the excretion of 17-OHCS. This kind of reaction was not found in the allergics and the difference between allergics and healthy subjects was also significant." The weak reaction of allergics was attributed to decreased reactivity to stressors. The eosinophil count was not consistently affected by the sauna.

Collins, K. J., Few, J. D., Forward, T. J., Giec, L. A.: "Stimulation of adrenal glucocorticoid secretion in man by raising the body temperature." *J. Physiol. (Lond.)* **202**: 645-660 (1969). G68,085/69

Plasma cortisol and corticosterone concentrations increased significantly in eleven resting, unacclimatized subjects after two hours of exposure to heat. At the same time, the urinary elimination of 17-OHCS showed no significant change. Alteration in plasma cortisol specific activity after intravenous injection of radiocortisol indicated that the raised plasma concentrations were due mainly to increased adrenal secretion, although this was accompanied by more rapid removal of cortisol from the circulation in hot environments.

Budd, G. M., Warhaft, N.: "Urinary excretion of adrenal steroids, catecholamines and electrolytes in man, before and after ac-

climatization to cold in Antarctica." *J. Physiol. (Lond.)* **210**: 799-806 (1970).

G79,783/70

The urinary excretion of corticoids and 17-KS rose while that of EP and NEP remained unchanged in men exposed to cold in Antarctic regions. Comparable studies during previous Antarctic expeditions are reviewed.

Wilson, O., Hedner, P., Laurell, S., Nosslin, B., Rerup, C., Rosengren, E.: "Thyroid and adrenal response to acute cold exposure in man." *J. Appl. Physiol.* **28**: 543-548 (1970).

G76,132/70

In man, acute exposure to cold sufficient to cause a .5°C decrease in rectal temperature as well as a rise in plasma cortisol and catecholamine excretion did not change the thyroid hormone level in blood, thyroid hormone turnover, thyroid hormone binding protein or plasma TTH. Presumably, "in man a relatively severe cold exposure of 3 hours does not measurably stimulate the pituitary-thyroid axis, but seems to increase the adrenal activity by moderately increasing the corticosteroid as well as the catecholamine output." It remains to be seen whether the activation of the pituitary-adrenocortical axis is due to the physical or emotional effects of cold (40 refs.).

Golstein-Golaire, J., Vanhaelst, L., Bruno, O. D., Leclercq, R., Copinschi, G.: "Acute effects of cold on blood levels of growth hormone, cortisol, and thyrotropin in man." *J. Appl. Physiol.* **29**: 622-626 (1970).

G79,353/70

In man, two hours' exposure to a temperature of 4° C caused no change in plasma STH concentrations and only moderate variations in plasma cortisol, but TTH values rose as expected.

Bertin, R.: "Influence de l'adaptation à la température sur quelques hormones surrénales du rat" (Influence of adaptation to temperature upon some adrenal hormones in the rat). *J. Physiol. (Paris)* **63**: 204-207 (1971).

G85,537/71

Adaptation to cold increases NEP production in rats and at the same time augments the plasma and adrenal concentration of corticosterone in a lasting manner. However, adaptation to heat diminishes the level of both corticoid and catecholamine. Adaptation to fluctuating temperatures does not augment NEP secretion but persistently raises plasma corticosterone.

Studies on the release and synthesis of hypothalamic STH-releasing factor in rats exposed to heat. In general, resynthesis keeps pace with the discharge of the releasing factor (27 refs.).

Wilkerson, J. E., Raven, P. B., Bolduan, N. W., Horvath, S. M.: "Adaptations in man's adrenal function in response to acute cold stress." *J. Appl. Physiol.* **36**: 183-189 (1974). J10,302/74

In man, exposure to temperatures of 15°C or less acted as a "cold stress." "Because of increased circulating levels of cortisol, epinephrine, and norepinephrine, it was concluded that sympathoadrenal function in unacclimatized males was markedly altered" (45 refs.).

Panarett, B. A.: "Relationship of visceral blood flow to cortisol metabolism in cold-stressed sheep." *J. Endocrinol.* **60**: 235-245 (1974). H83,404/74

As long as sheep exposed to cold are capable of maintaining their body temperature, plasma cortisol levels are raised conjointly with cortisol metabolic clearance rates (radiocortisol). With continued exposure the animals lose their ability to maintain normal rectal temperatures, and plasma cortisol levels rise still further, but the metabolic clearance rates fall significantly below normal. The latter change is largely ascribed to reductions in hepatic and renal blood flow.

Mueller, G. P., Chen, H. T., Dibbet, J. A., Chen, H. J., Meites, J.: "Effects of warm and cold temperatures on release of TSH, GH, and prolactin in rats." *Proc. Soc. Exp. Biol. Med.* **147**: 698-700 (1974). H98,469/74

In rats, exposed to heat or cold, the fact that TTH and LTH secretion "responded oppositely to the same temperature changes suggests that different mechanisms regulate release of these two hormones under these conditions. The possible role of stress, and the interactions of the hypothalamic hypo-

physiotropic hormones and biogenic amines in the temperature-induced changes remain to be evaluated."

Francesconi, R. P., Boyd, A. E. III, Mager, M.: "Human tryptophan and tyrosine metabolism: effects of acute exposure to cold stress." *J. Appl. Physiol.* **33**: 165-169 (1972). J11,247/72

In men exposed to cold stress, the circadian variations of plasma cortisol were diminished and body temperature dropped. Although the total plasma amino acid content was not affected, tryptophan and tyrosine levels were lowered. An associated increase in the excretion of two major tryptophan metabolites (*kynurenic* and *xanthurenic acids*) suggested enhanced activity of hepatic tryptophan oxygenase, presumably in order to make these two amino acids more readily available for protein, hormone, and biogenic amine synthesis during stress.

Okada, Y., Matsuoka, T., Kumahara, Y.: "Human growth hormone secretion during exposure to hot air in normal adult male subjects." *J. Clin. Endocrinol. Metab.* **34**: 759-763 (1972). H54,871/72

In four normal obese adult males exposed to hot air (48°C) for one hour after an overnight fast, elevation of body temperature was associated with increased plasma STH and FFA levels. No significant changes in cortisol, total thyroxine-iodine, blood glucose or hematocrit were noted during heat exposure. In two subjects, administration of glucose before heat prevented the rise in plasma STH.

Cantfort, J. van: "Influence du 'stress' sur l'activité de la cholestérol- 7α -hydroxylase" (Effects of "stress" on cholesterol- 7α -hydroxylase activity). *C.R. Acad. Sci. (Paris)* **277**: 345-348 (1973). J6,396/73

In normal animals, the *cholesterol-7 α -hydroxylase* activity of the liver shows a circadian rhythm with a maximum at the beginning of the night. This is controlled by the hypothalamus-pituitary-adrenal axis and is abolished by adrenalectomy. Corticoids and various stressors increase this enzyme activity in the rat.

Polis, B. D., Polis, E., Schwarz, H. P., Dreisbach, L.: "The effect of cold on the composition of the phospholipids of the blood plasma of healthy athletes." *Proc. Soc. Exp. Biol. Med.* **145**: 70-73 (1974). J21,416/74

In athletes, the *phosphatidyl glycerol* content of plasma was very significantly elevated immediately after and for seven minutes following exposure to cold.

Sabbot, I., Costin, A.: "Cold stress induced changes in the uptake and distribution of radiolabelled *magnesium* in the brain and pituitary of the rat." *Experientia* **30**: 905-906 (1974). H92,909/74

Chirpaz, F., Lafrance, L., Leblanc, J.: "Effets de la noradrénaline sur le métabolisme des acides gras libres du plasma chez des rats adaptés au froid" (Effects of noradrenaline on plasma *free fatty acid* metabolism in rats adapted to cold). *Ann. ACFAS* **41**: 175 (1974). H88,198/74

Francesconi, R. P., Mager, M.: "Cold exposure: effect on hepatic tryptophan oxygenase and tyrosine aminotransferase, plasma tryptophan and tyrosine, and brain monoamines." *Experientia* **30**: 233-235 (1974). H86,502/74

In mice, exposure to "cold stress" rapidly enhances the production of *tryptophan oxygenase* and *tyrosine aminotransferase*. However, "there are no general correlations between increased activity of these catabolic enzymes and reduced levels of plasma trypto-

phan, tyrosine, and brain norepinephrine and serotonin.... Our results indicate that if the rate limiting enzymes in serotonin and norepinephrine biosynthesis, tryptophan and tyrosine hydroxylases respectively, are stimulated by cold stress, then homeostatic conditions are maintained by increased levels of catabolic activity."

H80,745/74

In sheep, "heat stress" diminishes fertility. [Other stressors have not been used for comparison to determine the nonspecificity of this result (H.S.).]

+Restraint. Lange, K., Gold, M. M. A., Weiner, D., Kramer, M.: "Factors influencing resistance to cold environments." *Bull. U.S. Army* **8**: 849-859 (1948).

B23,962/48

The survival time of restrained rabbits is greatly diminished at -20° C and their body temperature drops precipitously.

Bartlett, R. G., Miller, M. A.: "The adrenal cortex in restraint hypothermia and in adaptation to the stress of restraint." *J. Endocrinol.* **14**: 181-187 (1956).

C25,043/56

In rats, mild restraint for one week increased the ascorbic acid and to a lesser extent the cholesterol content of the adrenals. Restraint sufficiently severe to reduce body temperature produced inverse changes. Loss of adrenal cholesterol and ascorbic acid from

the adrenals was particularly severe in animals restrained while exposed to cold.

Frankel, H. M.: "Effects of restraint on rats exposed to high temperature." *J. Appl. Physiol.* **14**: 997-999 (1959). J11,919/59

Restraint diminishes the resistance of rats to high temperatures, although the final rectal temperatures are not greatly different.

Brodie, D. A., Valitski, L. S.: "Production of gastric hemorrhage in rats by multiple stresses." *Proc. Soc. Exp. Biol. Med.* **113**: 998-1001 (1963). E28,039/63

"Gastric hemorrhage was produced in 93% of rats subjected to cold + restraint stress for 60 minutes." This combination of stressors also elicited a marked depression of body temperature lasting three hours after the stress. "Anticholinergics, ganglionic blocking agents, certain central nervous system depressants and epinephrine reduced the incidence of hemorrhage."

Robert, A., Phillips, J. P., Nezamis, J. E.: "Production, by restraint, of gastric ulcers and of hydrothorax in the rat." *Gastroenterology* **51**: 75-81 (1966). G40,473/66

In rats, restraint produced gastric ulcers and hydrothorax within four to six hours. Overnight fasting prevented the hydrothorax and reduced the gastric ulcerations (contrary to previous reports). Restraint ulcers and hydrothorax "were also inhibited by crowding of the animals, a rise in ambient temperature, or administration of prednisolone."

Buchel, L., Gallaire, D.: "Influence de la température ambiante sur la production d'ulcères de contrainte chez le rat" (Influence of surrounding temperature on the production of restraint ulcers in rats). *C.R. Soc. Biol. (Paris)* **160**: 1817-1820 (1966).

F78,016/66

A decrease of the surrounding temperature from 24 to 14° C facilitates the production of restraint ulcers in rats, whether or not they are previously exposed to twenty-four hours of fasting. Yet starvation accelerates the development of such restraint ulcers. Body temperature does not appear to be the only important factor, for rats kept at warm temperatures (28-32° C) still show gastric erosions, whereas treatment with phenobarbital or chloral hydrate during restraint aggravates the hypothermia and yet diminishes ulcer frequency.

Buchel, L., Gallaire, D.: "Ulcères de contrainte chez le rat. I. Influence, sur la fréquence des ulcères, du jeûne et de la tempér-

ature de l'environnement associés à des immobilisations de durées variables" (Restraint ulcers in the rat. I. Influence of fasting and environmental temperature associated with restraint of variable duration on the incidence of restraint ulcers). *Arch. Sci. Physiol.* **21**: 527-536 (1967).

G53,615/67

In rats, twenty-four hours of fasting increases the incidence of gastric ulcers produced by subsequent restraint. Concurrent exposure to cold further sensitizes the stomach to the development of these stress ulcers.

Senay, E. C., Levine, R. J.: "Synergism between cold and restraint for rapid production of stress ulcers in rats." *Proc. Soc. Exp. Biol. Med.* **124**: 1221-1223 (1967).

F83,370/67

The authors present a technique for the acute production of gastric ulcers in rats within two hours by combined exposure to restraint and cold.

Martin, M. S., André, C., Martin, F., Lambert, R.: "Rôle du froid dans l'ulcère de contrainte chez le Rat" (Effects of cold on restraint ulcers in rats). *C.R. Soc. Biol. (Paris)* **163**: 158-161 (1969).

H14,537/69

In rats, restraint at 5°C is highly effective in producing gastric ulcers within three hours and a concurrent drop in rectal temperature.

Martin, M. S., Martin, F., Lambert, R.: "The effect of ambient temperature on restraint ulcer in the rat." *Digestion* **3**: 331-337 (1970).

H34,597/70

In rats, the incidence of gastric ulcers produced by restraint increased considerably as the ambient temperature was lowered from 28 to 19°C. However, no strict correlation was observed between body temperature and frequency of gastric lesions. Restraint during the active phase of their diurnal cycle was particularly effective in producing gastric ulcers in the rats, and cold augmented wakefulness.

Ivanova, G. N., Altukhova, V. I., Kenig, E. E., Skebelskaia, I. B.: "Functional condition of the adrenal cortex of guinea pigs under conditions of prolonged and continuous overheating." *Probl. Endokrinol.* **18** No. 5: 98-103 (1972) (Russian).

H60,926/72

In guinea pigs, overheating at 35°C from five hours up to twenty-one days reduced the adrenocortical response to the stress of restraint, but did not alter blood 17-OHCS levels or reactivity to exogenous ACTH. "A conclusion could be drawn that reduced re-

sponse to stress in these animals was associated with a lesser excretion of endogenous ACTH."

Djahanguiri, B., Taubin, H. L., Landsberg, L.: "Increased sympathetic activity in the pathogenesis of restraint ulcer in rats." *J. Pharmacol. Exp. Ther.* **184**: 163-168 (1973).

H65,010/73

In rats, exposure to cold greatly increased the production of gastric ulcers by restraint. α -Methyldopa, bretylium, phenoxybenzamine and phentolamine all reduced the incidence of such gastric ulcerations. "The results suggest that the increased turnover of norepinephrine may be causally related to the development of restraint ulcers."

Yano, S., Harada, M.: "A method for the production of stress erosion in the mouse stomach and related pharmacological studies." *Jap. J. Pharmacol.* **23**: 57-64 (1973).

H85,804/73

Stress ulcers of the stomach can be most reliably produced in mice by immersing them in water of 25°C for eighteen hours while they are enclosed in a restraint cage of special design. The technique is said to be particularly useful in the assay of drugs inhibiting such erosions. Curiously, immersion at lower or higher temperatures causes less severe gastric ulcers.

Buchel, L., Murawsky, M.: "Métabolisme et activité de la zoxazolamine chez le rat blanc au cours de l'immobilisation forcée accompagnée ou non d'hypothermie" (Zoxazolamine metabolism and activity in white rats during restraint with or without hypothermia). *Arch. Sci. Physiol.* **27**: 37-53 (1973).

J7,077/73

In rats, the muscle-relaxing effect of zoxazolamine is considerably enhanced by the stress of restraint, especially in cold surroundings. This is ascribed mainly to increased sensitivity of the nervous system and (to a lesser extent) to impaired zoxazolamine metabolism during stress.

Hadjiolova, I.: "Veränderungen des Plasma- und Nebennierenrindencorticosterons bei Ratten während Hypokinesie und zusätzlicher Stress-Einwirkungen" (Influence of hypokinesia and subsequent stress upon rat plasma and adrenal corticosterone levels). *Int. Arch. Arbeitsmed.* **33**: 59-70 (1974).

J17,473/74

Studies on plasma and adrenal corticosterone in rats exposed to different stressors (heat, restraint, noise) alone or in combina-

tion. "A moderate increase in the levels of both plasma and adrenal corticosterone was observed after 24 hours of hypokinesia. In a subsequent period of 60 days the corticosterone levels did not differ significantly from the levels found in the control animals. However, a marked decrease in adrenal weight and a slighter response to additional thermal stress were demonstrated after 60 days of hypokinesia. Differences between the restrained and the control animals were also found in the adaptation to chronic auditory stress."

+**Genetics.** Deane, H. W., Lyman, C. P.: "Body temperature, thyroid and adrenal cortex of hamsters during cold exposure and hibernation, with comparisons to rats." *Endocrinology* **55**: 300-315 (1954).

B97,428/54

In both hibernating and nonhibernating Syrian hamsters, exposure to cold causes no significant adrenal enlargement or histologic evidence of hyperactivity similar to that produced in rats. However, the hamster adrenal is sensitive to other stressors.

Raths, P., Schulze, W.: "Die Nebennieren des Goldhamsters im Winterschlaf und bei anderen Aktivitätszuständen" (The adrenals of the golden hamster during hibernation and other activities). *Z. Biol.* **109**: 233-243 (1957). C36,859/57

Detailed description of histologic changes in the adrenal medulla and cortex of the golden hamster during hibernation, awakening from hibernation, and during anesthesia induced by cold.

D'Angelo, S. A.: "Adenohypophyseal function in the guinea pig at low environmental temperature." *Fed. Proc.* **19** Supp. 5: 51-56 (1960). C97,820/60

The relationship between adrenal and thyroid stimulation was studied in cold-exposed guinea pigs after electrocautery of the hypothalamus.

Yoon, Y. H.: "Pathological studies on the baby pig with hypoglycemia." *J. Kor. Vet. Med. Assoc.* **6**: 1222-1232 (1962) (Korean with English summary). G16,777/62

In baby pigs, stress induced by exposure to cold or starvation caused changes typical of the G.A.S., such as loss of adrenal lipids, hypoglycemia and eosinopenia (24 refs.).

Schwarz, D.: "Die Änderung der unspezifischen Reaktion des Organismus unter Hitzeanpassung" (Changes in the nonspecific

reaction of the organism during heat adaptation). *Dtsch. Versuchsanstalt für Luft- und Raumfahrt No. 441*: 1-71 (1965).

F72,209/65

Doctoral thesis containing a detailed analysis of the roles of stress and stress hormones in man's adaptive reactions to heat, with particular emphasis on aerospace medicine (242 refs.).

Pegelman, S. G., Kanarik, U. K.: "Adaptive responses in guinea pigs under conditions of a prolonged cooling." *Sechenov Physiol. J. U.S.S.R.* **53** No. 10: 1212-1217 (1967) (Russian).

J13,141/67

In guinea pigs, exposure to cold causes marked adrenal hypertrophy and ascorbic acid depletion with eosinopenia. Pretreatment with ascorbic acid reverses the eosinophil response and virtually blocks the loss of ascorbic acid from the adrenals.

Henschel, A.: "Obesity as an occupational hazard." *Can. J. Public Health* **58**: 491-493 (1967) (15 refs.). E71,837/67

Strydom, N. B., Williams, C. G.: "Effect of physical conditioning on state of heat acclimatization of Bantu laborers." *J. Appl. Physiol.* **27**: 262-265 (1969) (15 refs.).

J14,803/69

Slee, J.: "Resistance to body cooling in male and female sheep, and the effects of previous exposure to chronic cold, acute cold and repeated short cold shocks." *Anim. Prod.* **12**: 13-21 (1970). J10,493/70

The resistance of shorn female sheep to cold can be greatly increased by a single previous exposure of a few hours. Females are more resistant to cooling than males. Daily short cold shocks reduced cold resistance and inhibited acclimatization in females but not in males.

Maloiy, G. M. O.: "The effect of dehydration and heat stress on intake and digestion of food in the Somali donkey." *Environ. Physiol. Biochem.* **3**: 36-39 (1973).

H79,366/73

+**Drugs or Hormones.** Maickel, R. P., Westermann, E. O., Brodie, B. B.: "Effects of reserpine and cold-exposure on pituitary-adrenocortical function in rats." *J. Pharmacol. Exp. Ther.* **134**: 167-175 (1961).

D48,441/61

Reserpine and those reserpine derivatives that decrease brain NEP and 5-HT produced sedation and ACTH hypersecretion in rats. Large doses of reserpine or prolonged cold

exposure decreased the ACTH content of the pituitary sufficiently to prevent a detectable discharge in response to other stressors.

Juszkiewicz, T.: "Effects of chlorpromazine, reserpine, and ascorbic acid in resisting heat stress in rats." *Am. J. Vet. Res.* **22**: 537-543 (1961). J11,417/61

In rats, pretreatment with chlorpromazine, reserpine or ascorbic acid failed to prevent, but did somewhat diminish, the loss of adrenal ascorbic acid produced by heat (43°C).

Juszkiewicz, T., Jones, L. M.: "The effects of chlorpromazine on heat stress in pigs." *Am. J. Vet. Res.* **22**: 553-557 (1961).

J10,364/61

As indicated by adrenal ascorbic acid determinations, "chlorpromazine diminishes stressful response of the pituitary-adrenal axis in pigs due to hyperthermia, increases the survival rate at 40°C, and decreases the body weight loss."

Taylor, R. E. Jr., Fregly, M. J.: "Effect of reserpine on body temperature regulation of the rat." *J. Pharmacol. Exp. Ther.* **138**: 200-207 (1962). D41,319/62

In rats, intraperitoneal reserpine diminishes body temperature much more at low than at high environmental temperatures. It acts by decreasing heat production rather than by increasing heat loss. Restraint augments the reserpine-induced decrease in body temperature.

Johnson, G. E., Flattery, K. V., Schönbaum, E.: "The influence of methimazole on the catecholamine excretion of cold-stressed rats." *Can. J. Physiol. Pharmacol.* **45**: 415-421 (1966). F66,195/66

In rats, exposure to cold increases urinary excretion of NEP and thyroid activity. Failure to secrete adequate amounts of NEP and, in its absence, of EP, results in hypothermia and death. If cold-acclimated rats are treated with the antithyroid drug methimazole, the excretion of free EP and NEP doubles. It is postulated that the increase in the secretion of EP and NEP after exposure to cold results from a decrease in the intrinsic metabolic activity of catecholamines, and is a compensatory mechanism for the maintenance of heat production.

Goldstein, M., Nakajima, K.: "The effect of disulfiram on the biosynthesis of catecholamines during exposure of rats to cold." *Life Sci.* **5**: 175-179 (1966). G36,828/66

In rats, increased catecholamine excretion during exposure to cold suggests increased activity of the sympatho-adrenal system. Disulfiram, a potent inhibitor of dopamine- β -hydroxylase, causes only a slight decrease in the cardiac NEP concentration in adrenalectomized rats at room temperature. In animals kept 2°C for one hour there is a 50 percent decrease in cardiac NEP concentration, as compared with NEP levels in the corresponding controls. The fact that cold decreases the cardiac NEP content following inhibition of dopamine- β -hydroxylase by disulfiram "suggests an increase in cardiac norepinephrine utilization during cold exposure." In otherwise untreated animals, cardiac NEP levels after cold exposure are sustained by an increase in the biosynthesis of these catecholamines. It is possible that the increase in NEP biosynthesis during cold is due to excess dopamine formation.

Takagi, K., Okabe, S.: "An experimental gastric ulcer of the rat produced with anticholinergic drugs under stress." *Eur. J. Pharmacol.* **5**: 263-271 (1969). H9,358/69

In rats, the stress ulcers produced by immersion in cold water are prevented by atropine and other anticholinergic agents but at the same time another type of ulcer appears in the proventriculus.

Boulu, R., Schwartz, J. C.: "Ulcères gastriques médicamenteux et température environnante" (Drug-induced gastric ulcers and environmental temperature). *C. R. Acad. Sci. (Paris)* **268**: 2507-2510 (1969). G67,252/69

In rats, the production of gastric ulcers by reserpine, phenylbutazone and deoxy-2-glucose is much higher at an environmental temperature of 20°C than at 37°C.

Leduc, J.: "Effet de la sympathectomie chez le rat exposé au froid" (Effect of sympathectomy in rats exposed to cold). *Ann. ACFAS* **40**: 128 (1973). H87,897/73

6-Hydroxydopamine, which causes a "chemical sympathectomy," greatly diminishes resistance to cold. There is a marked rise in urinary EP but not in NEP. Apparently, the adrenal medulla can largely compensate for the loss of sympathetic nerve activity.

Osumi, Y., Takaori, S., Fujiwara, M.: "Preventive effect of fusaric acid, a dopamine- β -hydroxylase inhibitor, on the gastric ulceration induced by water-immersion stress

in rats." *Jap. J. Pharmacol.* **23**: 904-906 (1973). H82,948/73

Earlier observations had shown that EP and NEP can inhibit the production of stress ulcers in the stomach of the rat. It had also been noted that most α -adrenergic-blocking agents as well as the release of endogenous monoamines by reserpine and tetrabenazine aggravate these lesions, while β -adrenergic-blocking agents inhibit them. In the present experiments rats immobilized in restraint cages were immersed up to the xyphoid in water at 21°C, which produced gastric ulceration within three hours. Tetrabenazine prior to the stress aggravated ulcer production, while concurrently eliciting a decrease in NEP and dopamine content. Fusaric acid (5-butylpicolinic acid), a potent inhibitor of dopamine- β -hydroxylase, exerted an antiulcerogenic effect that was presumably due to a decrease in the release of NEP from the CNS.

Dechezleprêtre, S., Lechat, P.: "Effets comparés de l'adrénaline et d'un stress aigu sur la glycémie, la lactacidémie et la corticostérone plasmatique et surrénaliennes du rat" (Comparison of the effects of epinephrine and acute stress on glycemia, lactacidemia and the corticosterone level of plasma in the adrenals of the rat). *Agressologie* **15**: 117-123 (1974). H93,830/74

In rats, acute exposure to cold causes marked hyperlactacidemia, mild hyperglycemia and a considerable increase in plasma and adrenal corticosterone levels. These changes reach their maximum within ten minutes. EP exerts a similar effect but this is due to the stressor action of the injection procedure, as it is also produced by injection of the solvent alone. The changes elicited by combined treatment with cold and EP are not greater than those caused by the two agents separately.

+**Trauma.** Brunt, E. E. van, Ganong, W. F.: "The effects of preanesthetic medication, anesthesia and hypothermia on the endocrine response to injury." *Anesthesiology* **24**: 500-514 (1963). E23,121/63

Detailed review of the literature on the influence of preanesthetic medication and hypothermia upon the stressor effects of surgical injuries.

Markley, K., Smallman, E., Thornton, S. W.: "The effect of environmental temperature on mortality and metabolism after burn

and tourniquet trauma." *Fed. Proc.* **31**: 817 (1972). H53,564/72

An environmental temperature of 31°C significantly reduced mortality in mice after burn and tourniquet trauma.

Markley, K., Smallman, E., Thornton, S. W., Evans, G.: "The effect of environmental temperature and fluid therapy on mortality and metabolism of mice after burn and tourniquet trauma." *J. Trauma* **13**: 145-160 (1973). J1,495/73

Partially shaved and hairless mice kept at 31°C survive burn and tourniquet trauma better than those kept at 25°C.

+**Age.** Cooke, R. E., Pratt, E. L., Darrow, D. C.: "The metabolic response of infants to heat stress." *Yale J. Biol. Med.* **22**: 227-249 (1950) (52 refs.). B30,242/50

Grad, B., Kral, V. A.: "The effect of senescence on resistance to stress: I. Response of young and old mice to cold." *J. Gerontol.* **12**: 172-181 (1957).

C33,287/57

Adaptation to cold was less readily acquired by old than by young mice. "The fatal failure of old mice to adapt to cold generally occurred early in the stress period, that is, in the alarm phase of the Selye's adaptation syndrome."

Haltmeyer, G. C., Denenberg, V. H., Thatcher, J., Zarrow, M. X.: "Response of the neonatal rat after subjection to stress." *Nature* (Lond.) **212**: 1371-1373 (1966).

F74,906/66

During the first five days of life, the stress of heat or electric shock raises the adrenal and plasma concentration of corticosterone in the rat. Manifestly, the neonatal rat adrenal can respond normally to stressors by both an increased synthesis and release of corticoids. These data contradict earlier reports of a "stress-non-responsive period" (SNR) in this species. When adrenal ascorbic acid depletion is used as an indicator the situation appears to be different. Reactivity also depends upon the stressor (20 refs.).

Riccio, D. C., Campbell, B. A.: "Adaptation and persistence of adaptation to a cold stressor in weanling and adult rats." *J. Comp. Physiol. Psychol.* **61**: 406-410 (1966).

F76,331/66

No major difference in adaptability to cold was observed between weanling and adult rats "when severity of the stressor was

equated on the basis of previously reported behavioral and physiological measures."

Campbell, B. A., Riccio, D. C.: "Cold-induced stress in rats as a function of age." *J. Comp. Physiol. Psychol.* **64**: 234-239 (1966). G39,214/66

Comparative studies in animals of different age groups exposed to cold showed that "initial colonic temperatures were lower and behavioral recovery times slower in weanling rats, whereas colonic temperature-recovery times did not vary with age."

Danilova, L. Y.: "The role of adrenal glands in the regulation of carbohydrate metabolism of undercooled animals having different degrees of thermoregulation." *Acta Biol. Med. Germ.* **21**: 625-634 (1968) (Russian). H7,143/68

In various premature (although not in mature) neonatal mammals, cooling is not accompanied by glycogenolysis due to an insufficient EP secretion. Glucocorticoids raise the hepatic glycogen reserves in newborns, but fail to increase their resistance to hypothermia.

Fennell, W. H., Moore, R. E.: "Peripheral vascular responses to heat stress in elderly men." *Int. J. Biometeorol.* **15**: 325-329 (1971). J20,332/71

Wagner, J. A., Robinson, S., Tzankoff, S. P., Marino, R. P.: "Heat tolerance and acclimatization to work in the heat in relation to age." *J. Appl. Physiol.* **33**: 616-622 (1972). H79,771/72

Males aged eleven to sixty-seven years were compared in standard work-heat stress (walking on a treadmill in dry heat). "The older men had lower coefficients of heat conductance and finger blood flow in the heat than the young men. During work in the heat the older men and preadolescent boys were more limited in the sensitivity and secretory capacity of the sweating mechanism than the young men and the older boys."

Lyle, J. G., Jonson, K. M., Edwards, M. J., Penny, R. H.: "Effect of prenatal heat stress at mid- and late gestation on the learning of mature guinea-pigs." *Dev. Psychobiol.* **6**: 483-494 (1973). J8,629/73

In guinea pigs subjected to "heat stress" prenatally, black-white serial discrimination was impeded, and often morphologic evidence of brain damage became detectable.

Anagnostakis, D., Economou-Mavrou, C.,

Agathopoulos, A., Matsaniotis, N.: "Neonatal cold injury: evidence of defective thermogenesis due to impaired norepinephrine release." *Pediatrics* **53**: 24-28 (1974). J9,386/74

In preterm neonates exposed to cold, urinary excretion of NEP was considerably lower than after recovery. Urinary excretion of EP was unaffected by cold stress. Possibly, exposure of the newborn to cold exhausts the NEP stores and thereby causes inability to stimulate and utilize chemical thermogenesis.

+Diet. Horst, K., Mendel, L. B., Benedict, F. G.: "The metabolism of the albino rat during prolonged fasting at two different environmental temperatures." *J. Nutr.* **3**: 177-200 (1930). 6,639/30

Rats fasting at 26°C lived on the average 16.5 days and lost 49 percent of their initial body weight, whereas those fasting at 16°C survived on the average eleven days and lost 44 percent of their weight.

Mitchell, H. H., Edman, M.: *Nutrition and Climatic Stress*, p. 235. Springfield, Ill.: Charles C Thomas, 1951. B65,070/51

Technical discussion of observations on stress caused by cold, heat, high altitude and acceleration in relation to the nutrition of man (more than 750 refs.).

Leduc, J.: "Catecholamine production and release in exposure and acclimation to cold." *Acta Physiol. Scand.* **53** Supp. 183: 1-101 (1961). D42,829/61

Review of personal observations indicating that "warm- and cold-acclimated rats could not withstand prolonged exposure to cold after restriction of food. Their catecholamine excretion rapidly attained maximal values and animals died in hypothermia. The same happened with warm-acclimated rats whose insulation has been reduced by removal of the fur. Cold-acclimated clipped rats survived in the cold, but their catecholamine response was much more intense than that of intact cold-acclimated animals." Allegedly, these experiments suggest that acclimation to cold is limited by the finite capacity of the body to produce catecholamines and thereby maintain thermal balance. EP is considered to be a defense hormone against cold.

Boulouard, R.: "Effects of cold and starvation on adrenocortical activity of rats." *Fed. Proc.* **22**: 750-754 (1963). E20,995/63

In rats, starvation brings about a very significant increase in plasma corticosterone which is even more considerable in the event of simultaneous exposure to cold. The relationship between these findings and Porter-Silber chromogens is discussed. The strongest adrenocortical response occurs during the first few days of exposure to cold; secretion diminishes later despite the continued maintenance of adrenocortical hypertrophy.

Heim, T., Kellermayer, M.: "The effect of environmental temperature on brown and white adipose tissue in the starving newborn rabbit." *Acta Physiol. Acad. Sci. Hung.* **31**: 339-346 (1967). G50,688/67

The effect of stress upon fat mobilization was studied in newborn rabbits starved to death at different environmental temperatures. "Brown fat is mobilized in response to cold but not during starvation in a thermo-neutral environment, whereas white fat apparently serves as a general metabolic reserve and is used during starvation both in the absence and the presence of a cold induced increase in heat production."

Hale, H. B., Mefford, R. B. Jr.: "Influence of chronic heat exposure and prolonged food deprivation on excretion of magnesium, phosphorus, calcium, H⁺ and ketones." *Aerospace Med.* **39**: 919-926 (1968). G63,858/68

Description of the metabolic changes produced in rats by the "interplay of two stressors, chronic heat exposure and prolonged food deprivation."

Brooke, O. G., Harris, M., Salvosa, C. B.: "The response of malnourished babies to cold." *J. Physiol. (Lond.)* **233**: 75-91 (1973). J5,659/73

In malnourished Jamaican children heat production was not increased and rectal temperature fell when environmental temperature was decreased from 28° to 25°C.

+Rays. Gambino, J. J., Bennett, L. R., Billings, M. S., Lamson, B. G.: "Biological effect of stress following ionizing radiation." *Aerospace Med.* **35**: 220-224 (1964).

G9,697/64

Review of the literature on the effect of hypothermia upon x-ray resistance. Rats given a single dose of 500 rads (total body irradiation) showed "reduced longevity; retarded growth; cataracts; accelerated onset of skin ulcers, greying, enlarged mammary glands and palpable tumors; and increased incidence of palpable tumors." Repeated ex-

posure to brief periods of cold did not significantly influence these changes with the possible exception of tumorigenesis (41 refs.).

Reinhardt, K.: "Bestrahlung, insbesondere lokal- und fraktionierte Bestrahlung in Hypothermie bei der Ratte" (Irradiation, especially local and fractionated irradiation, during hypothermia in rats). *Strahlentherapie* **132**: 274-283 (1967). G45,682/67

In rats, induced hypothermia protects against local and whole body x-irradiation.

Musacchia, X. J., Barr, R. E.: "Helium-cold induced hypothermia in the hamster and radio-resistance." *Physiologist* **10**: 257 (1967). F86,700/67

In hamsters rendered hypothermic by being placed in an 80 percent helium, 20 percent oxygen atmosphere at low temperatures, resistance to cobalt irradiation is increased.

Phillips, R. D., Kimeldorf, D. J.: "An immediate irradiation effect on resistance of rats to low temperature." *J. Appl. Physiol.* **24**: 768-772 (1968). G58,748/68

Phillips, R. D., Kimeldorf, D. J.: "Effect of X-irradiation on the resistance of rats to low temperature." *Fed. Proc.* **27**: 508 (1968). H565/68

In rats exposed to cold after whole body x-irradiation, survival time was diminished.

+Varia. Caldwell, F. T. Jr.: "Metabolic response to thermal trauma: II. Nutritional studies with rats at two environmental temperatures." *Ann. Surg.* **155**: 119-126 (1962).

G48,655/62

At an environmental temperature of 30°C rats with skin burns gained weight and maintained a positive nitrogen balance without mortality. At 20°C animals with similar wounds lost weight rapidly, showed negative nitrogen balance and had a 60 percent mortality rate, although in both groups food intake was maintained at a preburn level. When the rats were allowed free access to food, the striking difference between those kept at 20°C and those kept at 30°C after burn was not seen. Normally, the burned rats consumed more food than the controls.

Handler, E.: "Temperature effects on operator performance." In: Burns, N. M., Chambers, R. M. et al., *Unusual Environments and Human Behavior*, pp. 321-352. Glencoe, Ill.: Free Press, 1963. E10,431/63

Review on the effect of high and low temperatures on performance with special reference to aerospace medicine.

Rosenberg, A.: "Production of gastric lesions in rats by combined cold and electrostress." *Am. J. Dig. Dis.* **12**: 1140-1148 (1967). G51,611/67

In rats, combined exposure to cold and *electrostress* was much more effective in producing gastric lesions than either of these stressors alone. "The cold-electrostress-induced gastric lesions were prevented by atropine sulfate, atropine methyl nitrate and propantheline." Several other central depressants were less effective or ineffective.

Morimoto, T., Slabochova, Z., Naman, R. K., Sargent, F.: "Sex differences in physiological reactions to thermal stress." *J. Appl. Physiol.* **22**: 526-532 (1967).

G45,267/67

Skreslet, S., Aarefjord, F.: "Acclimatization to cold in man induced by frequent scuba diving in cold water." *J. Appl. Physiol.* **24**: 177-181 (1968). G55,183/68

Scuba *divers* practicing in cold water go through three stages of acclimatization: 1) unacclimatized stage: cold stress is met with by an elevated metabolic rate compensating heat loss. 2) intermediate stage: there is a fall in the rectal (core) temperature as heat loss is not fully compensated for by metabolism, believed to be caused by habituation of the CNS. 3) acclimatized stage: a constant rectal temperature is maintained, although minor metabolic heat is produced. Conservation of heat is attributed to lowered heat transfer with the blood to the body surface." [It is difficult to establish to what extent these reactions are truly nonspecific and hence characteristic of stress as such rather than of cold (H.S.).]

Stone, E. A.: "Behavioral and neurochemical effects of acute swim stress are due to hypothermia." *Life Sci.* **9** No. 1: 877-888 (1970). G77,276/70

In rats, forced *swimming* at 15°C causes hypothermia, inactivity and reduction of brain NEP. These changes can be prevented by rapid rewarming or by swimming in 37°C water.

Patton, G. W. R.: "Combined autonomic effects of concurrently-applied stressors." *Psychophysiology* **6**: 707-715 (1970).

H47,514/70

In U.S. soldiers, the stress effects (pulse rate, blood pressure, skin conductance) of solving *anagrams* during exposure to cold were greater than when each stressor was applied alone.

"Fully acclimatized subjects may show a smaller adverse effect of thermal stress on *G tolerance*, attributable to the cardiovascular changes which characterize this adaptive response."

Davis, F. M., Charlier, R., Saumarez, R., Muller, V.: "Some physiological responses to the stress of aqualung diving." *Aerosp. Med.* **43**: 1083-1088 (1972).

G95,712/72

Scuba (aqualung) *diving* in British coastal waters caused hormonal changes characteristic of stress. "Plasma cortisol levels were significantly raised before and after 30-meter dives when compared with 3-meter dives. Raised urinary levels of adrenalin, with high adrenalin to noradrenalin excretion ratios, were seen in several divers. The average decrease in rectal temperature was 0.33°C and mean skin temperatures remained approximately 16°C above ambient water temperature. Cold stress was considered unlikely to contribute to the hormonal changes seen."

These changes are probably due to anxiety over deep open water diving in a 'stressful' diving situation" (22 refs.).

Hale, H. B., Williams, E. W., Ellis, J. P. Jr.: "Cross-adaptation in military trainees in a hot climate." *Aerosp. Med.* **43**: 978-983 (1972). J2,006/72

Young men were exposed to *hyperoxia*, heat or both agents combined. "Differences in the metabolic response patterns of the trainees studied in summer and winter strongly suggest that heat adaptation led to positive cross-adaptation."

Iampietro, P. F., Melton, C. E. Jr., Higgins, E. A., Vaughan, J. A., Hoffmann, S. M., Funkhouser, G. E., Saldivar, J. T.: *High Temperature and Performance in a Flight Task Simulator*, pp. 1-8. Washington, D.C.: Federal Aviation Administration, 1972.

G91,965/72

In a *flight task simulator*, performance definitely declined at high cockpit temperatures. Relationships to the classic manifestations of the stress syndrome are not discussed.

Tanaka, M.: "Experimental studies on human reaction to cold with reference to differences between males and females." *Bull. Tokyo Med. Dent. Univ.* **19**: 1-18 (1972).

H56,898/72

When they were exposed to cold, heat production was lower in *women* than in men, but the decrease in skin temperature was more pronounced in males. Urinary 17-KS concentrations increased in the male but not in the female.

Tillman, F. R., Miller, J. A. Jr.: "Hypothermia and resistance of mice to lethal exposures to high gravitational forces." *Aerosp. Med.* **43**: 860-866 (1972). H79,348/72

Senay, L. C. Jr.: "Body fluids and temperature responses of heat-exposed women before and after ovulation with and without rehydration." *J. Physiol. (Lond.)* **232**: 209-219 (1973). J4,529/73

Personal observations and review of the literature on *sex* differences in the response of men and women to "heat stress." No special mention is made of any typical stress phenomena.

Wells, C. L., Horvath, S. M.: "Heat stress responses related to the menstrual cycle." *J. Appl. Physiol.* **35**: 1-5 (1973). J4,516/73

The few changes occurring during the *menstrual cycle* had a minimal influence upon

the ability of normal women "to regulate body temperature when exposed to environmental heat stress."

Wyndham, C. H.: "The physiology of exercise under heat stress." *Ann. Rev. Physiol.* **35**: 193-220 (1973). H67,021/73

Review on the physiology of *muscular exercise* "under heat stress," with special reference to metabolic and vascular reactions. Very little attention is given to stress in general or to adaptive hormones (122 refs.).

Harrison, M. H.: "Comparison of the metabolic effects of centrifugation and heat stress in man." *Aerosp. Med.* **44**: 299-303 (1973). H80,109/73

In fasted men, the stress of *centrifugation* or exposure to heat increased blood lactate, glucose, FFA, glycerol and catecholamine levels, but these changes did not always parallel each other (30 refs.).

Claus-Walker, J., Halstead, L. S., Carter, R. E., Campos, R. J., Spencer, W. A., Canzoneri, J.: "Physiological responses to cold stress in healthy subjects and in subjects with *cervical cord injuries*." *Arch. Phys. Med.* **55**: 485-490 (1974) (20 refs.).

J19,762/74

Dechezleprêtre, S., Lechat, P.: "Effets comparés de l'adrénaline et d'un stress aigu sur la glycémie, la lactacidémie et la corticostérone plasmatique et surrénalienne du rat" (Comparison of the effects of epinephrine and acute stress on glycemia, lactacidemia, and the plasma and adrenal corticosterone levels in the rat). *Aggressologie* **15**: 117-123 (1974). H93,830/74

In rats, acute exposure to cold causes marked hyperlactacidemia and mild hyperglycemia, with a considerable increase in plasma and adrenal corticosterone levels. These changes reach their maximum within ten minutes. EP exerts a similar effect due to the stressor action of the injection procedure, since it is also produced by injection of the solvent alone. The changes elicited by combined treatment with cold and EP are not greater than those caused by the two agents separately.

Poulton, E. C., Edwards, R. S.: "Interactions and range effects in experiments on pairs of stresses: mild heat and low-frequency noise." *J. Exp. Psychol.* **102**: 621-628 (1974). J17,212/74

Review of the literature on the interaction between the stressor effects of heat and *noise* in man.

Morimoto, T., Shiraki, K., Asayama, M.: "Seasonal difference in responses of body fluids to heat stress." *Jap. J. Physiol.* **24**: 249-262 (1974). J15,690/74

Wessenberg, H.: "The pathogenicity of *Entamoeba histolytica*: is heat stress a factor?" *Perspect. Biol. Med.* **17**: 250-266 (1974).

H81,930/74

Review of the literature and personal observations suggest that heat stress, especially in combination with physical exertion and solar radiation, predisposes to *infection* with

Entamoeba invadens and *histolytica*. In military epidemics, the emotional factor of anxiety also plays an important role. "Whether or not heat stress is the directly antecedent cause of tissue invasion, the lesson seems clear regarding the danger of heat stress to carriers of the amoebae or to those exposed to infection" (66 refs.).

Chou, B. J., Besh, E. L.: "Feeding bio-rhythm alterations in heat-stressed rats." *Aerosp. Med.* **45**: 535-539 (1974).

J13,391/74

Burns

→**Morphology.** Among the morphologic changes now known to be primarily dependent upon stress, gastroduodenal ulcer formation in man was probably one of the first to be observed. As early as 1823 Swan, and in 1839 Cooper, clearly described the development of bleeding surface erosions or even deep ulcers in the gastric and duodenal mucosa of severely burned children. These findings were repeatedly confirmed in adults also, both before and after 1842 when Curling described the lesions which now bear his name.

Similar changes have been reproduced experimentally in animals, although it was not until the alarm reaction was described in 1936 that they were recognized as being part of the characteristic stress reaction, and not a specific effect of some "burn toxin." Following extensive superficial skin burns, gastrointestinal lesions were often associated with adrenal changes, particularly red discoloration, which was regarded as a sign of hyperemia or hemorrhagic infarction with necrosis, but later it was also ascribed to simple hyperactivity with discharge of the cortical lipid granules. Yet, very severe burns may also cause necrosis and hemorrhage as well as deplete medullary catecholamines, and in some cases treatment with corticoids and/or catecholamines has been considered to be of therapeutic value.

→**Hormones.** Burns, if sufficiently severe, can produce pronounced increases in ACTH, glucocorticoid and catecholamine secretion, both in experimental animals and in man. Despite the many claims to the contrary, there is no convincing evidence of an exhaustion of the hormone-producing capacity of the pituitary or adrenals after severe burns, although cortical necrosis may cause some degree of relative adrenal insufficiency. The increase in the urinary secretion of corticoids and catecholamines is most pronounced during the first twenty-four hours after burns. This is when the adrenal stores of these hormones are correspondingly most markedly depleted, since resynthesis is slower than discharge. It is at this time, not during the stage of exhaustion, that we may speak of a functional adrenal insufficiency, but it is usually transient and rarely the cause of death. The excess secretion of corticoids and catecholamines is generally associated with all the other classic signs of the G.A.S.

In patients with severe burns, an increase in immunoreactive plasma STH and in-

sulin allegedly may persist for several weeks, but eventual exhaustion of the β -cells can cause "dangerous burn stress pseudodiabetes."

The plasma renin and angiotensin II concentrations have also been claimed to exhibit a very high rise, persisting for days or weeks.

→Metabolites. The biochemical changes most characteristic of stress, that occur as a consequence of burns, have already been discussed in the previous section devoted to the metabolism of hormones and hormone-like substances. Since burns, especially if they are extensive, undoubtedly represent extremely powerful systemic stressors, they are also associated with all other chemical manifestations of the stress syndrome, including intense catabolism with the liberation of breakdown products from protein, fat and carbohydrate stores.

It is worth noting, however, that in burned patients the BMR rises even in the absence of fever. Furthermore, plasma renin and angiotensin II are often unusually high and this elevation may persist for weeks. It may be related to the renal and hepatic damage associated with burns, but its pathogenesis has not yet been established.

→Varia. The renal complications of severely burned patients have received considerable attention, but it remains to be shown to what extent they depend upon stress as such. On the other hand, the characteristic eosinopenia and lymphopenia are undoubtedly the consequences of increased glucocorticoid production elicited by burns. The hypercoagulability of the blood, often observed in burned or severely traumatized patients, appears to be a result of a stress-induced derangement in platelet function. In rats, skin burns reduce the radioiodine uptake by the thyroid within a few hours, but it remains unexplained why this and other stressors may cause either hyper- or hypothyroidism, depending upon circumstances.

Data on complex psychologic defense mechanisms mobilized by patients under life-threatening stress, including burns, are not yet sufficiently understood to justify detailed evaluation here.

+Varia. In certain cases, corticoids have been recommended for the treatment of burns (especially in children), but their efficiency is still dubious.

In rats with extensive skin burns, maintenance of a positive N balance and survival are certainly better at high than at low surrounding temperatures. Normally, burned rats consume more food than controls unless they are in extremely poor general condition. If the animals are given free access to food, a striking difference between those kept at low and high temperatures is less evident.

Burns

Annotated review of the literature on burns, quoting many observations on their relation to the G.A.S. (703 refs.).

→**Ulcers.** Swan, J.: "Burns." *Mth. Gaz. Health* **8**: 612-613 (1823). 6,901/1823

Swan, J. "Practical observations." *Edinb. Med. J.* **19**: 344-347 (1823). 11,389/1823

Probably the first descriptions of what is now known as a "stress ulcer," in a five-year-old child who died from severe burns. "At different times he vomited a blackish matter, and the day before he died, appeared so weak and cold, that a little wine and sago were given him. On opening the abdomen, every part appeared sound, except the stomach, in the villous coat of which were several black spots and stripes like sloughs, extending deep, and quite black.... There can be no doubt that the diseased appearances of the head of the stomach were produced by the irritation of the skin."

Cooper, S.: "Pathology of burns and scalds." *Lond. Med. Gaz.* **23**: 837-838 (1839). 72,145/1839

In an eight-year-old girl who died about five weeks after severe scalds of the chest, an ulcer "about the size of a shilling" was noted in the duodenum just beyond the pylorus. Duodenal ulcers were also found after scalds and burns in other children.

Long, J.: "On the post-mortem appearances found after burns." *Lond. Med. Gaz.* **25**: 743-750 (1840). B4,643/1840

One of the first detailed descriptions of perforating duodenal ulcers in patients who died from extensive burns. "I have been induced to give the two cases of perforation of the duodenum in detail, as I believe they are unique; indeed I am not aware of any case being recorded, of perforation of the gastrointestinal tube occurring after a burn, except the one I have quoted from Liston, which approximates to my two cases by the perforation being near the pylorus, and by the change which had taken place in the duodenum."

Pack, G. T.: "The pathology of burns." *Arch. Pathol.* **1**: 767-805 (1926).

A15,632/26

In a review on the pathology of burns it is stated that "the inconstant duodenal ulcer of burns is due either to the irritant action of the bile, which owes its injurious ability to its content of the presumptive burn toxin, or to the production of infarction of the duodenal mucosa by septic emboli."

McLaughlin, C. W.: "The Curling ulcer. Study of intestinal ulceration associated with suprarenal damage." *Arch. Surg.* **27**: 490-505 (1933). 92,906/33

In man as in animals, superficial burns can produce peptic ulcers as well as adrenal lesions. Experiments on the dog show that extensive partial adrenalectomies are often conducive to duodenal ulcers, and hence the adrenal lesions may predispose to burn-induced peptic ulcerations (42 refs.).

Harkins, H. N.: "Acute ulcer of the duodenum (Curling's ulcer) as a complication of burns: relation to sepsis." *Surgery* **3**: 608-641 (1938) (134 refs.). E87,072/38

tical function in burn stress." In: Artz, C. P., *Research in Burns*, pp. 163-170. Washington, D.C.: American Institute of Biological Sciences, 1962.

J11,913/62

Severe cutaneous burns may cause adrenal hemorrhage and necrosis in man.

Haynes, B. W. Jr., Lounds, E. A., Hume, D. M.: "Adrenocortical function in severe burns." *Sci. Progr. Am. Assoc. Surg. Trauma* p. 16 (1963).

J11,914/63

Following a transient period of increased corticoid and catecholamine secretion, severely burned patients may exhibit signs of adrenocortical insufficiency.

Foley, F. D., Pruitt, B. A. Jr., Moncrief, J. A.: "Adrenal hemorrhage and necrosis in seriously burned patients." *J. Trauma* 7: 863-870 (1967).

H3,644/67

Six cases of fatal adrenal hemorrhage and necrosis among 1,213 patients with cutaneous burns (21 refs.).

→**Hormones.** Talbot, N. B., Albright, F., Saltzman, A. H., Zygmuntowicz, A., Wixom, R.: "The excretion of 11-oxy corticosteroid-like substances by normal and abnormal subjects." *J. Clin. Endocrinol.* 7: 331-350 (1947).

98,831/47

In man, "non-specific trauma (Alarm Reaction) resulted in a rise of urinary 11-OHCS assays; thus, values of the order of magnitude found in Cushing's syndrome were obtained in three patients with severe burns, the excretion falling to normal in one of these patients, interestingly enough, about three days before a fatal issue."

Hume, D. M., Nelson, D. H., Miller, D. W.: "Blood and urinary 17-hydroxycorticosteroids in patients with severe burns." *Ann. Surg.* 143: 316-329 (1956).

C15,326/56

17-OHCS levels in the plasma and urine of severely burned patients were greatly increased, and continued examinations revealed no evidence of adrenal exhaustion. Indeed, the adrenal was capable of responding to exogenous ACTH during the postburn period (10 refs.).

Goodall, M., Stone, C., Haynes, B. W. Jr.: "Urinary output of adrenaline and noradrenaline in severe thermal burns." *Ann. Surg.* 145: 479-487 (1957).

C33,346/57

In patients who suffered severe burns, the urinary output of EP and NEP was greatly increased. In one group of burned patients,

all of whom died, there was an initial rise of NEP but only a moderate elevation of EP output (74 refs.).

Birke, G., Dunér, H., Liljedahl, S. O., Pernow, B., Plantin, L. O., Troell, L.: "Histamine, catechol amines and adrenocortical steroids in burns." *Acta Chir. Scand.* 114: 87-98 (1958).

J10,862/58

In severely burned patients, blood and urinary histamine, EP and NEP content, as well as the excretion of corticoids (17-KGS) were considerably increased during the first twenty-four hours, but the duration of the rise varied according to the substances examined. Their role in the genesis of burn shock is discussed.

Goodall, M., Haynes, B. W. Jr.: "Adrenal medullary insufficiency in severe thermal burn." *J. Clin. Invest.* 39: 1927-1932 (1960).

G98,084/60

Review of the literature and personal study of fourteen fatally burned patients show that approximately two-thirds of these have subnormal EP output and low EP content in the adrenals, suggesting an acute medullary insufficiency. "In some patients the inflow, or rate of resynthesis, is apparently inadequate to meet the heavy demands imposed by the severe 'stress' of burn and, consequently, the adrenals are emptied of their adrenaline storage" (47 refs.).

Egdahl, R. H.: "Adrenal cortical and medullary responses to trauma in dogs with isolated pituitaries." *Endocrinology* 66: 200-216 (1960).

J11,920/60

In dogs, urinary 17-OHCS levels were increased for about five days after removal of the brain above the inferior colliculus. Burns caused a further increase. The catecholamine levels were initially low, but rose after burns.

Timmer, R. F.: "Changes in corticosterone levels after severe stress in the rat." *Proc. Soc. Exp. Biol. Med.* 110: 694-697 (1962).

D32,903/62

In rats, severe burns raised the plasma corticosterone level. "Measurements of free corticosterone in 'burn tissue fluid' indicated that the maximum value occurred at three hours after stress."

Hulbanni, S. V., Desai, R. C., Vyas, B. K.: "The role of adrenal cortex in stress of burns." *Indian J. Med. Res.* 54: 1083-1086 (1966).

F77,680/66

In burned patients, urinary corticoid levels reach a maximum on the third day and are

roughly proportional to the severity of the injury. This is associated with eosinopenia whose intensity does not adversely affect prognosis. The changes are considered characteristic of the G.A.S.

Franzen, F., Friedrich, G., Gross, H.: "Normabweichendes Auftreten proteinogener Amine bei Verbrennungskranken" (Abnormal activities of proteinogenic amines in burned patients). *Z. Gesamte Inn. Med.* **22**: 401-404 (1967).

F87,778/67

In severely burned patients, the plasma and urinary concentrations of EP, NEP, 5-HT, histamine and other amines derived from protein decomposition are greatly increased. There is no evidence to suggest that these changes are due to stress rather than to the specific effect of burns.

Muzykant, L. I., Gordeev, V. F.: "On the system of hypothalamus-hypophysis-adrenal in burn disease." *Ekspl. Khir. Anesteziol.* **14** No. 4: 42-47 (1969).

H16,736/69

Review on the G.A.S. manifestations produced by burns. The reactions of the hypothalamus-pituitary-adrenal system are essentially the same as those elicited by other stressors.

Wase, A. W., Repplinger, E.: "The effect

of thermal burns on the thyroid activity of the rat." *Endocrinology* 53: 451-454 (1953).

B87,006/53

Review of earlier literature showing that under certain circumstances stressors may produce either hyper- or hypothyroidism. Skin burns reduce radioiodine uptake by the rat thyroid during the first four hours.

Sevitt, S.: "Adrenocortical function in burned patients with special reference to ACTH and adrenaline tests." *Br. Med. J.* March 6, 1954, pp. 541-546. B91,174/54

In severely burned patients, adrenocortical hyperactivity was established by their spontaneous eosinopenia and their strong response to ACTH and EP. Only in fatal or near fatal burns were these responses deficient.

Wilson, H., Lovelace, J. R., Hardy, J. D.: "The adrenocortical response to extensive burns in man." *Ann. Surg.* 141: 175-184 (1955). C16,145/55

As indicated by the rise in urinary corticoids and the eosinopenia, "the stress response in a severe burn is one of the most intense of which the body is capable."

Gelfand, D. W., Goldman, A. S., Law, E. J., MacMillan, B. G., Larson, D., Abston, S., Schreiber, J. T.: "Thymic hyperplasia in children recovering from thermal burns." *J. Trauma* 12: 813-817 (1972).

G94,744/72

In children recovering from burns, the thymus is often enlarged.

Eurenius, K., Rothenberg, J.: "Platelet aggregation after thermal injury." *J. Lab. Clin. Med.* 83: 355-363 (1974). J10,809/74

As indicated by ADP-induced platelet aggregation in rats, platelet function was markedly depressed during the first hours after scalds, concurrently with the transient appearance of a plasma inhibitor. These changes may contribute to the "hypercoagulability" frequently described in burned or traumatized patients (37 refs.).

Beathard, G. A., Granholm, N. A., Sakai, H. A., Ritzmann, S. E.: "Ultrastructural alterations in peripheral blood lymphocyte profiles following acute thermal burns." *Clin. Immunol. Immunopathol.* 2: 488-500 (1974). J15,203/74

In man, during the immediate postburn period "a marked defect in cellular immunity or T-cell function occurs simultaneously with a marked stimulation in humoral immunity

or B-cell function. The latter abnormality is reflected by the development of a polyclonal gammopathy and the development first of a marked B-lymphocytosis followed by a marked plasmacytosis" that coincides with a return to normal peripheral blood lymphocyte counts (39 refs.).

Goldman, A. S., Rudloff, H. B., McNamee, R., Loose, L. D., Luzio, N. R. di: "Deficiency of plasma humoral recognition factor activity following burn injury." *J. Reticuloendothel. Soc.* 15: 193-198 (1974). J12,833/74

"Plasma humoral recognition factor activity, which is essential for optimal phagocytosis, is significantly depleted in severely burned children, both in the presence or absence of bacteremia, as well as in burned rats." This may explain the increased susceptibility to infection following thermal injury (30 refs.).

Dressler, D. P., Skornik, W. A.: "Pulmonary bacterial susceptibility in the burned rat." *Ann. Surg.* 180: 221-227 (1974). J15,111/74

Exposure of burned and control rats to *P. aeruginosa* and *S. aureus* showed that susceptibility to pulmonary infection is greatly increased within twenty-four hours of thermal injury.

+Varia. Duncan, J. T. Jr.: "Adrenal insufficiency in thermal burn with septicemia. Successful replacement therapy." *Am. Surg.* 20: 57-59 (1954). J10,792/54

In a patient with adrenal insufficiency due to septicemia following a burn, cortisone was very efficacious as replacement therapy.

Caldwell, F. T. Jr.: "Metabolic response to thermal trauma: II. Nutritional studies with rats at two environmental temperatures." *Ann. Surg.* 155: 119-126 (1962). G48,655/62

At an environmental temperature of 30°C, rats with skin burns gained weight and maintained a positive nitrogen balance without mortality. At 20°C, animals with similar wounds lost weight rapidly, showed a negative nitrogen balance and had a 60 percent mortality rate although in both groups food intake was maintained at a preburn level. When the rats were allowed free access to food, the striking difference between those kept at 20°C and those kept at 30°C after burn was not seen. Normally, the burned rats consumed more food than the controls.

Langlois, P., Williams, H. B., Gurd, F. N.: "Effect of an elemental diet on mortality rates and gastrointestinal lesions in experimental burns." *J. Trauma* 12: 771-777 (1972). G94,742/72

Rats fed an "*elemental diet*" in which amino acids replaced all the protein showed

improved survival and diminished gastrointestinal lesions after burns.

Voorhis, C. C., Law, E. J., MacMillan, B. G.: "Operative treatment of Curling's ulcer in children: report of four cases with three survivors." *J. Trauma* 14: 175-180 (1974).

J10,330/74

Sound

The stressor effect of sound has been the subject of extensive investigations both in man and in experimental animals, especially because of the importance of "sound pollution" in modern cities, particularly in factories and around airports. For general orientation about the relevant literature (including the specific effects of sound upon the auditory apparatus), see the many reviews and monographs cited below. Attention should be called to the fact that a certain amount of sound (such as that generated by movements of coworkers in an office) is often beneficial through its arousal effect; and music is commonly employed in industry, especially for the relief of workers engaged in monotonous tasks. On the other hand, prolonged exposure to continuous and intense noise can definitely be conducive to typical diseases of adaptation.

→**Morphology.** Not unexpectedly, intense noise also produces all the morphologic changes characteristic of stress, both in experimental animals and in man. Thus, in mice, the adrenals are enlarged and show histologic signs of hyperactivity, and the eosinophil count drops rapidly, even before there is evidence of thymic lymphatic involution. In rats, repeated intense auditory stimulation induces ovarian, uterine and hepatic atrophy in combination with adrenal enlargement. Numerous other observations confirm that sound acts essentially as do other stressors. However, a few structural changes are worthy of special note.

Some investigators reported changes in the salivary and lacrimal glands of rats exposed to stress, although these claims could not be uniformly confirmed.

The audiovisual stress produced by various bells, buzzers and white noise generators may influence the atherogenic effect of thiouracil in rats on a high cholesterol diet, but here again, confirmatory data by other laboratories are lacking.

Both sound and electroshock allegedly increase the incidence of dental caries in rats and may cause "fluctuating dental asymmetry."

→**Hormones.** The hormonal changes produced in animals and man by exposure to intense sound are essentially the same as those elicited by other stressors. Particularly characteristic is the discharge of ACTH, glucocorticoids and catecholamines. The plasma STH level may also rise in persons exposed to intense noise in an industrial plant, as well as in squirrel monkeys in which this response is similarly elicited by a variety of other psychogenic stressors.

Intense auditory stimulation increases corticoid production and causes a fall in brain NEP. Furthermore, changes in the 5-HT content of the amygdala and temporal cor-

tex are considered in support of the hypothesis that 5-HT may inhibit the transmission of impulses through the auditory pathways.

Urinary VMA elimination was increased among workers exposed to industrial noise in factories. A rise in catecholamine excretion has also been noted in aircraft factory workers exposed to turbine noise.

In rhesus monkeys, plasma glucagon rose rapidly when they were startled by noise and this was not necessarily associated with any significant changes in plasma insulin. Similar effects were produced, even under light anesthesia, by drilling a burr hole in the skull, electroshock, rectal distention and other stressors.

→**Metabolites.** In rats, strong auditory stimulation allegedly reduced the glutathione level of the blood simultaneously with an actual increase in the ascorbic acid and cholesterol content of the adrenals.

In workers exposed to noise and vibration in a factory, serum aldolase and lactic dehydrogenase rose, supposedly as a nonspecific consequence of stress.

In guinea pigs, prolonged exposure to noise caused a variety of enzymologic changes ascribed to the alarm and resistance stages of the G.A.S.

In lambs, auditory stimulation was followed by a rise in plasma FFA, and the same was true in aircraft factory workers exposed to turbine noise.

Most of the other biochemical changes produced by noise in different species correspond to those elicited by other stressors, and do not deserve special mention.

→**Nervous System.** Continuous or interrupted strong auditory stimulation is generally known to cause psychogenic distress, usually accompanied by such objective indices of the G.A.S. as increased catecholamine and corticoid secretion. However, here again, our motto applies: "it is not so much what happens to you but the way you take it." Certain musical sounds are either relaxing or eustress-producing to most people, and there exist transitional situations such as are created by extremely strong music (for example, calypso) which is as pleasant to some as it is painful to others. Even the crying of a baby who wants milk or simply attention may be eustressful to the mother and distressful to others.

Most of the scientific work on the stressor effect of noise has been done in genetically predisposed mice or rats which develop epileptic-type convulsions under the influence of audiogenic stimulation—and many pertinent additional data will also be found in the section on Genetics. There is no convincing evidence, however, that the hereditary predisposition of these animals to convulsions is truly nonspecific and could be elicited by any other stressors.

→**Varia.** Among other manifestations of prolonged audiogenic stimulation, blood pressure instability usually resulting in hypertension has been reported in various susceptible species. In rats in which strong sound caused convulsive attacks, these were associated with an increased phagocytosis by leukocytes. In the absence of convulsions, the same sound produced an opposite effect. In various mammals, chronic exposure to intense sound disturbed the sexual cycle and fertility, presumably as a consequence of the "shift in hypophyseal hormone production."

In rats, intense sound decreased antithrombin and thromboplastin activity, but activated antithromboplastin. Thrombocyte adhesiveness after auditory stress may predispose to thrombosis in man.

+Genetics. Among the factors that influence responsiveness to sound, genetic predisposition is probably one of the most important. There are strains of mice and rats which develop intense and sometimes fatal audiogenic convulsions. These have been compared with epileptic seizures and are associated with eosinopenia, thymus involution and other characteristic manifestations of the alarm reaction. In man, EEG studies indicate that noise has comparatively little effect upon the sleep patterns of twenty-five-year-old subjects, but causes increasingly severe disturbances with progressing age.

Sound, like many other stressors, raises plasma cortisol in the carp.

→**Hormones.** Fortier, C.: "Studies on the adrenocorticotrophic effect of audiogenic stimulation." *Rev. Can. Biol.* **10**: 67 (1951). B49,477/51

Henkin, R. I., Knigge, K. M.: "The effects of sound on the hypothalamic-pituitary-adrenal axis." *Acta Endocrinol.* **51** Supp.: 39 (1960). C93,250/60

The discharge of corticosterone following exposure to sound is prevented if the reception of the stimulus by the auditory system is blocked. After twelve hours of continuous sound, hormone secretion diminishes.

Argüelles, A. E., Ibeas, D., Ottone, J. P., Chekherdemian, M.: "Pituitary-adrenal stimulation by sound of different frequencies." *J. Clin. Endocrinol. Metab.* **22**: 846-852 (1962). D28,851/62

In healthy young men, and even more markedly in anxious psychoneurotic patients, exposure to various pure sound frequencies for one-hour periods caused substantial elevations in 17-OHCS and 17-KGS excretion. "Adrenal cortical function in man may be remarkably sensitive to auditory stimulation, probably through the effect of ACTH released by intense sound."

Henkin, R. I., Knigge, K. M.: "Effect of sound on the hypothalamic-pituitary-adrenal axis." *Am. J. Physiol.* **204**: 710-714 (1963). D62,084/63

In rats, exposure to intense sound caused an initial increase with a subsequent depression of corticosterone secretion. Destruction of the middle ear abolished this response, but bilateral lesions in the posterior hypothalamus raised the resting level of corticosterone secretion and diminished the reaction to sound.

Argüelles, A. E.: "Endocrine response to auditory stress of normal and psychotic subjects." In: Bajusz, E., *An Introduction to Clinical Neuroendocrinology*, p. 121. Basel and New York: S Karger, 1967. E6,579/67

Review on the effect of audiogenic stress

upon corticoid production in animals and man.

Brown, G. M., Schalch, D. S., Reichlin, S.: "Patterns of growth hormone and cortisol responses to psychological stress in the squirrel monkey." *Endocrinology* **88**: 956-963 (1971). H37.353/71

In squirrel monkeys, various stressors (capture, chair restraint, intense sound and aversive conditioning) increase plasma STH and cortisol levels but the two responses do not run parallel and are presumably regulated by diverse mechanisms. In the case of chair restraint, STH values fall to resting levels while cortisol continues to rise.

Favino, A., Scoz, R., Trecate, G.: "Effetti della stimolazione acustica sulla secrezione di ormone somatotropo umano" (Effect of acoustic stimulation on growth hormone secretion in man). *Boll. Soc. Ital. Biol. Sper.* **47**: 704-708 (1971). G89.995/71

In man, the intense noise of an industrial plant raised plasma STH levels. [No technical details are given (H.S.).]

Grisanti, G., Manzella, G., Martines, E., Adriano, M. P.: "Studio sperimentale sul comportamento delle catecolamine seriche umane in seguito ad intensa stimolazione acustica" (Experimental study of human catecholamine blood levels after intense acoustic stimulation). *Valsalva* **47**: 65-81 (1971). Slob, A., Wink, A., Radder, J. J.: "The effect of acute noise exposure on the excretion of corticosteroids, adrenalin and noradrenalin in man." *Int. Arch. Arbeitsmed.* **31**: 225-235 (1973). H93.238/73

EP and NEP excretion in control male students showed the anticipated drop on the second day of preparation for noise exposure, which was attributed to them "getting used" to the laboratory situation. No decrease was manifested, on the afternoon of the second day, by the group exposed to noise of 80 dB intensity at this time. Allegedly, this result was due to the "masking effect" of noise exposure upon both levels of excretion. Corticosteroid levels were not significantly affected at any time.

Calogero, B., Vetrano, G.: "Variations of the biogenic amines content in some different areas of the brain of rats subjected to physiological auditory stimulation and acoustic trauma." *Rev. Laryngol. Otol. Rhinol. (Bord.)* **94**: 429-443 (1973).

J9.516/73

In rats, intense sonic stimulation (120 decibels) produced adrenocortical activation and a fall in brain NEP. "Changes in 5-HT concentration in the amygdala and temporal cortex occurred under both moderate but prolonged (60 decibels) and intense (120 decibels) auditory stimulation. These data are in favour of a possible inhibitory role played by serotonin in the central auditory pathways." Plasma corticosterone levels were also raised. [It is not clear to what extent the brain catecholamine changes were due to stress or specifically to auditory stimulation (H.S.).]

Calogero, B.: "Variazioni del turnover delle amine biogene nel sistema nervoso centrale del ratto dopo stimolazione acustica" (Biogenic amine changes in the central nervous system following acoustic stimulation in the rat). *Minerva Otorinolaringol.* **23**: 55-60 (1973).

J4.054/73

Intense auditory stimulation causes significant changes in the catecholamine and 5-HT content of the temporal cortex, amygdala and hypothalamus of the rat. "Serotonin may inhibit the transmission of impulses through the auditory pathway under protracted stimulation."

"The sound-vibration stress in industry produces an impairment of the balance of the circulatory homeostasis." This is accompanied by an increase in the excretion of free and conjugated NEP and EP.

Bloom, S. R., Daniel, P. M., Johnston, D. I., Ogawa, O., Pratt, O. E.: "Release of glucagon, induced by stress." *Q. J. Exp. Psychol.* **58**: 99-108 (1973). G99,793/73

In both conscious and lightly anesthetized (pentobarbital) rhesus monkeys startled by noise, plasma glucagon rose rapidly, followed by an elevation of blood glucose but not of plasma insulin. Similar effects were produced in anesthetized animals by rectal distention, drilling a burr hole in the skull, or the passage of an electric current through the head. "These experiments show that glucagon is rapidly released in response to various types of stress."

Morelli, G., Bellotti, C., Perrella, F.: "'Stress' vibratorio nell'uomo: aspetti etiopatogenetici e lavorativi" (Vibrational stress in man: etiopathogenetic and working aspects). *Nuovo Arch. Ital. Otol.* **1**: 94-101 (1973). J7,745/73

In workers occupationally exposed to vibrations, a rise in blood cortisol and urinary VMA indicates a strong stress response. Industrial noise has similar effects.

Favino, A., Maugeri, U., Kauchtschischvili, G., Robustelli Della Cuna, G., Nappi, G.: "Radioimmunoassay measurements of serum cortisol, thyroxine, growth hormone and luteinizing hormone with simultaneous electroencephalographic changes during continuous noise in man." *J. Nucl. Biol. Med.* **17**: 119-122 (1973). J8,286/73

Ortiz, G. A., Argüelles, A. E., Crespin, H. A., Sposari, G., Villafañe, C. T.: "Modifications of epinephrine, norepinephrine, blood lipid fractions and the cardiovascular system produced by noise in an industrial medium." *Horm. Res.* **5**: 57-64 (1974). H81,167/74

In aircraft factory workers exposed to turbine noise for three hours, there was gener-

ally a marked elevation of catecholamine excretion, blood cholesterol levels, FFA values, blood pressure, and pulse frequency. Unexpectedly, the plasma corticoid concentrations were slightly subnormal but this may have been due to circadian variations.

Collu, R., Jéquier, J. C., Chabot, C., Letarte, J., Leboeuf, G., Ducharme, J. R.: "Pituitary response to auditory stress: effect of treatment with α -methyl-p-tyrosine (α -MT)." *Endocrinology* (In press).

J18,335/

In rats, auditory stress increases plasma corticosterone through catecholaminergic, and decreases plasma STH through noncatecholaminergic, pathways, as judged by the effect of pretreatment with α -MT.

→**Morphology.** Miline, R., Kochak, O.: "L'influence du bruit et des vibrations sur les glandes surrénales" (Effects of noise and vibration on the adrenal glands). *C.R. Assoc. Anat. (Paris)* **70**: 692-703 (1952).

B56,901/52

In guinea pigs and rabbits exposed to strong sounds and vibrations for twenty-four hours in a boiler-making factory, the adrenal changes were quite characteristic of the G.A.S.

Anthony, A., Ackerman, E.: "Effects of noise on the blood eosinophil levels and adrenals of mice." *J. Acoust. Soc. Am.* **27**: 1144-1149 (1955). E80,678/55

In C57 male mice, daily exposure to noise resulted in temporary eosinopenia after about three hours and later in adrenocortical hypertrophy. "No evidence was obtained of permanent compensatory adrenal hypertrophy, of thymicolympathic involution or other tissue injury. On the basis of this, it is concluded that the eosinophil and adrenal changes are manifestations of a normal physiological response to a sensory stimulus rather than a response to sound as a severe stressor agent." [The fact that mild stress is a physiologic state has not been considered (H.S.).]

Sackler, A. M., Weltman, A. S., Bradshaw, M., Jurtshuk, P. Jr.: "Endocrine changes due to auditory stress." *Acta Endocrinol. (Kbh.)* **31**: 405-418 (1959). C71,159/59

In rats, repeated exposure to strong auditory stimulation causes adrenal enlargement, ovarian atrophy and diminution in the weight of the uterus and liver. Food consumption is also markedly reduced.

Jurtshuk, P. Jr., Weltman, A. S., Sackler, A. M.: "Biochemical responses of rats to auditory stress." *Science* **129**: 1424-1425 C68,703/59 (1959).

In rats, prolonged intense auditory stimulation reduced the glutathione level of blood, simultaneously increasing the weight, ascorbic acid and cholesterol content of their adrenals.

Jensen, M. M., Rasmussen, A. F.: "Stress and susceptibility to viral infection. I. Response of adrenals, liver, thymus, spleen and peripheral leukocyte counts to sound stress." *J. Immunol.* **90**: 17 (1963). D54,097/63

In mice, three hours of exposure to high intensity sound induced adrenal hypertrophy. "Peripheral leukocyte counts responded biphasically to this stressor, exhibiting a leukopenia during and a leukocytosis following the stress period on each day. Leukopenia was not seen in stressed-adrenalectomized animals."

Croce, G.: "Lo 'stress' uditivo e le sue riverberazioni extralabirintiche" (Auditory stress and its labyrinthine rebound). *Valsalva* **40**: 381-384 (1964). J10,965/64

No definite changes were noted in the extraorbital lacrimal gland of the rat upon exposure to the stress of noise.

Fiori-Ratti, L., Croce, G., Simoncelli, C.: "Esperienze sullo stress sensoriale acustico. 1. Nota introduttiva. 2. La ghiandola paraparotide di Loewenthal del ratto" (Experiments on sensory acoustic stress. 1. Introductory note. 2. The paraparotid gland of Loewenthal in the rat). *Valsalva* **40**: 272-279; 280-291 (1964). G22,184/64

In rats, exposure to strong "acoustic stress" produces changes in the paraparotid gland of Loewenthal that are ascribed to stress [although they may be specific to sound (H.S.)], in addition to the characteristic signs of the G.A.S.

Croce, G., Simoncelli, C.: "Esperienze sullo 'stress' sensoriale acustico. Nota III. Le ghiandole sottomascellari di ratto nello 'stress' audiogeno" (Research on sensory acoustic stress. Note III. The submaxillary gland in rats after audiogenic stress). *Valsalva* **40**: 323-328 (1964). J10,966/64

In contradiction to earlier investigators who used other stressors, the authors were unable to produce any significant changes in the salivary glands of rats exposed to intense sound. [Under the conditions of this experi-

ment, other manifestations indicative of the G.A.S. were not reported (H.S.).]

Raab, W., Chaplin, J. P., Bajusz, E.: "Myocardial necroses produced in domesticated rats and in wild rats by sensory and emotional stresses." *Proc. Soc. Expt. Biol. Med.* **116**: 665-669 (1964). F17,034/64

"Wild rats exposed after periods of isolation to frightening noises (tape recording of hissing cat and squealing rat) displayed myocardial necroses in nearly 70% of the experiments."

Campus, S., Pandolfo, G., Accatino, G., Rappelli, A.: "Effetto degli stimoli psichici isolati sulla pressione arteriosa ed il peso corporeo di ratti Sprague-Dawley" (Effect of isolated mental stimuli on arterial pressure and body weight in Sprague-Dawley rats). *Boll. Soc. Ital. Biol. Sper.* **41**: 1087-1089 (1965). J22,723/65

Thiébaut, L., Berthelot, J., Blaise, S.: "Influence d'agressions systémiques sur l'évolution d'une réaction inflammatoire expérimentale. I. Effets d'un stress auditif" (Influence of systemic stresses on the development of an experimental inflammatory reaction. I. Effects of an auditory stress). *J. Physiol. (Paris)* **57**: 708-709 (1965). G57,900/65

Geber, W. F., Anderson, T. A., Dyne, B. van: "Physiologic responses of the albino rat to chronic noise stress." *Arch. Environ. Health* **12**: 751-754 (1966). G39,248/66

In rats, exposure to a variety of sounds (gongs, horns, loudspeakers, bells, vibrators) caused roughly parallel decreases in blood eosinophils and ascorbic acid concentrations in the adrenal and other tissues. On the other hand, chronic audiogenic stress led to a subsequent increase in adrenal weight and ascorbic acid concentrations as well as in serum cholesterol.

Reyna, L. J., DiMascio, A., Berezin, N.: "Psychological stress and experimental caries." *Psychosomatics* **8**: 138-140 (1967). F85,046/67

In rats, psychogenic stressors (electroshock, sound) can increase the incidence of dental caries.

Osintseva, V. P., Pushkina, N. N., Bonashevskaia, T. T., Kaverina, V. F.: "Noise-induced changes in the adrenal glands." *Gig. Sanit.* **34** No. 10: 119-122 (1969) (Russian). J15,752/69

Histologic studies on adrenal changes produced in rats by exposure to excessive noise.

Lipscomb, D. M.: "Indicators of environmental noise." In: Thomas, W. A., *Indicators of Environmental Quality*, pp. 211-241. New York: Plenum Press, 1972.

G99,061/72

General review on the stressor effects of sound with personal experiments on rats that developed a classic stress triad after exposure to broad-band continuous white noise of 110 decibels for forty-eight hours (136 refs.).

Siegel, M. I., Smookler, H. H.: "Fluctuating dental asymmetry and audiogenic stress." *Growth* 37: 35-39 (1973).

J8,473/73

Dental asymmetry has previously been ascribed to environmental stress. In this study pregnant rats were exposed to intermittent audiogenic stress. "The degree of fluctuating asymmetry of mandibular molar width and length was determined for stressed litters and shown to be significantly greater than for controls reared under normal laboratory conditions."

Geber, W. J.: "Inhibition of fetal osteogenesis by maternal noise stress." *Fed. Proc.* 32: 2101-2104 (1973).

H78,365/73

Bennett, T. E., Farwell, R. W., Anthony, A.: "Spiral ganglion RNA changes in rats exposed to acute noise stress" (abstracted). *Physiologist* 17: 179 (1974).

H89,871/74

→Metabolites. Anthony, A., Babcock, S.: "Effects of intense noise on adrenal and plasma cholesterol of mice." *Experientia* 14: 104-105 (1958).

D78,677/58

Under the experimental conditions reported here, exposure to five minutes of noise daily caused no adrenal hypertrophy, thymus involution or changes in serum and adrenal cholesterol in mice. Apparently, "homeostatic adjustment mechanisms of animals are not taxed to dangerous limits by intense sound stimulation." [The possibility that the exposure was too short is not considered (H.S.).]

Jurtshuk, P. Jr., Weltman, A. S., Sackler, A. M.: "Biochemical responses of rats to auditory stress." *Science* 129: 1424-1425 (1959).

C68,703/59

In rats, prolonged intense auditory stimulation reduced the glutathione level of the blood, simultaneously increasing the weight, ascorbic acid and cholesterol content of their adrenals.

Gregorczyk, J., Lewandowska-Tokarz, A., Stanosek, J., Hepa, J.: "The effects of physi-

cal work and work under conditions of noise and vibration on the human body. I. Behavior of serum alkaline phosphatase, aldolase and lactic dehydrogenase activities." *Acta Physiol. Pol.* 16: 701-708 (1965) (Polish).

F59,655/65

In men working in an industrial establishment where they were exposed to considerable noise and vibration, increases in serum aldolase and lactic dehydrogenase were interpreted as manifestations of the stress syndrome. "It was assumed that the aforementioned stress factors produce changes in the sugar metabolism of the body."

Jonek, J., Stanosek, J., Krauze, M., Waclawczyk, H.: "Histochemische Untersuchungen über das Verhalten einiger Enzyme in Nebennieren bei Meerschweinchen nach chronischer Lärmeinwirkung" (Histochemical examinations of various enzymes in the adrenals of guinea pigs after chronic exposure to noise). *Z. Mikrosk. Anat. Forsch.* 73: 174-186 (1965).

G38,514/65

In guinea pigs, chronic exposure to noise (kind not clearly described) produced characteristic histochemical changes in various enzyme activities which gradually tended to disappear; the changes were ascribed to the alarm and resistance stages of the G.A.S.

Józkiewicz, S., Puchalik, M., Cygan, Z., Dróżdż, M., Gregorczyk, J., Grzesik, J., Krzoska, K., Lewandowska-Tokarz, A., Stanosek, J., Źak, T.: "Studies on the effect of acoustic and ultrasonic fields on biochemical processes. IX. Effect on some blood components in workingmen under noisy conditions." *Acta Physiol. Pol.* 16: 727-737 (1965) (Polish).

F59,658/65

Bost, J., Dorleac, E.: "Influence de trois types de stimulation sonore sur le taux plasmatique des acides gras non estérifiés (FFA) chez le Mouton" (Effects of three types of auditory stimulation on plasma levels of non-esterified fatty acids in lambs). *C.R. Soc. Biol. (Paris)* 160: 2340-2343 (1966).

F80,786/66

In lambs, various types of auditory stimulation greatly increased plasma FFA, although adaptation occurred eventually.

Friedman, M., Byers, S. O., Brown, A. E.: "Plasma lipid responses of rats and rabbits to an auditory stimulus." *Am. J. Physiol.* 212: 1174-1178 (1967).

F83,722/67

"Rats exposed to a continuous sound stimulus having an intensity of 102 db and an intermittent sound stimulus (200-cycle

square wave with a duration of about 1 sec and having an intensity of 114 db) exhibited marked elevation and prolongation of clearing of postprandial plasma *triglyceride* for a period of approximately 21 days.... Cholesterol-fed rabbits exposed to similar sound stimulus for 10 weeks exhibited a higher blood *cholesterol* and more intense atherosclerosis than similarly fed control animals."

Croce, G., Frenguelli, A., Campora, E. de: "Esperienze sullo 'stress' sensoriale acustico. V. Il comportamento del sodio e del potassio nella ghiandola sottomascellare di ratto nello 'stress' audiogeno" (Experiments with acoustic sensory stress. V. Behavior of sodium and potassium in the rat submandibular gland in audiogenic stress). *Boll. Mal. Orecch.* **87**: 300-306 (1969). G74,773/69

The marked changes in salivary *potassium* and *sodium* in the submandibular glands of rats exposed to the stressor effect of sound indicate that the salivary glands are important "organs of stress."

Ortiz, G. A., Argüelles, A. E., Cresco, H. A., Sposari, G., Villaflaño, C. T.: "Modifications of epinephrine, norepinephrine, blood lipid fractions and the cardiovascular system produced by noise in an industrial medium." *Horm. Res.* **5**: 57-64 (1974). H81,167/74

In aircraft factory workers exposed to turbine noise for three hours, there was generally a marked elevation of catecholamine excretion, blood *cholesterol* levels, *FFA* values, blood pressure, and pulse frequency. Unexpectedly, the plasma corticoid concentrations were slightly subnormal but this may have been due to circadian variations.

→**Nervous System.** Korobow, N.: "Reactions to stress: a reflection of personality trait organization." *J. Abnorm. Soc. Psychol.* **51**: 464-468 (1955). J13,194/55

When speech is tape-recorded for immediate reproduction after a short time-lag, the subject, upon hearing his recorded speech while still talking, experiences "audiogenic stress" (AS) which leads to a breakdown in speech organization. The speech becomes halting with variations in speed, volume and integration, occasional repetition of words and phrases and addition of superfluous words. "Speech errors made under stress were analyzed to establish the degree of relationship with perception of the stress and personality traits."

Jerison, H. J.: "Effects of noise on human

performance." *J. Appl. Psychol.* **43**: 96-101 (1959). D54,809/59

Changes of performance in various environments "are discussed in terms of noise as a source of psychological stress."

Busnel, R. G., Lehmann, A.: "Effets synergiques de stimulations acoustiques et d'une situation 'stressante' sur des comportements globaux objectivables" (Synergistic effects of acoustic stimulation and of a "stressful" situation on total objectively-verifiable be-

havior). *C.R. Acad. Sci. (Paris)* **279**: 583-585 (1974). J17,619/74

Frankenhaeuser, M., Lundberg, U.: "Immediate and delayed effects of noise on performance and arousal." *Biol. Psychol.* **2**: 127-133 (1974). J19,036/74

Hartley, L. R., Adams, R. G.: "Effect of noise on the Stroop test." *J. Exp. Psychol.* **102**: 62-66 (1974). J17,211/74

In the Stroop color interference test, "color names written in inks of different hues, excluding ink of the hue the name indicates, are presented to Ss who are required to name the hue of the ink and not the color name." Brief exposure to noise is beneficial, whereas prolonged exposure to intense noise damages performance, in that elimination of the irrelevant interfering feature (color name) is more difficult during stress.

Brierley, H., Jamieson, R.: "Anomalous stress reactions in patients suffering from depression and anxiety." *J. Neurol. Neurosurg. Psychiatry* **37**: 455-462 (1974).

J13,469/74

The forearm muscle blood flow changes caused by the stressor effect of noise revealed that "depressive patients show something akin to a freeze response to stress, while patients with anxiety states show an arousal response."

→Varia. Medoff, H. S., Bongiovanni, A. M.: "Blood pressure in rats subjected to audiogenic stimulation." *Am. J. Physiol.* **143**: 300-305 (1945). 91,713/45

In old rats, unlike in young ones, daily audiogenic stimulation produces *hypertension*. The authors "believe this to be objective evidence for neurogenic influences in the etiology of hypertension."

McCann, S. M., Rothballer, A. B., Yeakel, E. H., Shenkin, H. A.: "Adrenalectomy and blood pressure of rats subjected to auditory stimulation." *Am. J. Physiol.* **155**: 128-131 (1948). A51,784/48

In rats, prolonged auditory stimulation produced *hypertension* that was favorably influenced by adrenalectomy. "It is suggested that the adrenal cortex mediated the elevation of blood pressure occurring during prolonged auditory stimulation."

Zondek, B., Tamari, I.: "Effect of audiogenic stimulation on genital function and reproduction." *Am. J. Obstet. Gynecol.* **80**: 1041-1048 (1960). D4,871/60

"Exposure to stimulation of the auditory organs in mature rats stimulates the anterior pituitary gonadotropic function, manifested by prolonged or persistent estrus, enlargement of the ovaries, and increase of the corpora lutea in number and size." In rabbits, enlargement of the ovaries and follicle hematomas with corpus luteum formation and sometimes galactorrhea are noted. The stimulating effect of auditory stimuli on female *genital function* is in contrast to the inhibitory action on fertility. The stressor effect of sound can also interrupt pregnancy.

Shatalov, N. N., Saitanov, A. O., Glotova, K. V.: "On the state of the cardiovascular system under conditions of exposure to continuous noise." *Gig. Tr. Prof. Zabol.* **6**: 10-14 (1962). J6,200/62

"In persons exposed to the effect of continuous industrial medium-frequency and high-frequency noise of intensity 85 to 120 db, functional disturbances of the *cardiovascular* system were frequently observed. Very often the subjects exhibited an instability of the arterial blood pressure. The electrocardiographic data showed bradycardia with a tendency to retardation of the intravesicular conductivity, plus a depression of the T-wave that was most frequently observed after physical stress and at the end of the work-period."

Rosecrans, J. A., Watzman, N., Buckley, J. P.: "The production of hypertension in male albino rats subjected to experimental stress." *Biochem. Pharmacol.* **15**: 1707-1718 (1966). G42,049/66

In rats subjected to "a chronic variable stress program consisting of flashing lights, audiogenic stimulation, and oscillation" *hypertension* developed after several months. This was associated with an increase in catecholamine excretion which disappeared after several weeks, and a rise in plasma corticosterone which tended to persist. "These results suggest that the adrenal glands had become more efficient in the rate of synthesis and release of steroids after chronic exposure to the stressors."

Ter-Markarian, N. G.: "Participation of adrenal glands and adrenocorticotrophic hormone of the hypophysis in changes of the phagocytic activity of blood leukocytes of rats in the action of a strong sound stimulus." *Probl. Endokrinol. Gormonoter.* **12** No. 5: 81-84 (1966) (Russian). F72,472/66

In rats, convulsive attacks induced by a

strong sound ("bell epilepsy") increased *phagocytosis* by leukocytes. In the absence of convulsions the same sound caused an opposite result in the rats. The effect of adrenalectomy and ACTH upon this phenomenon is also discussed. [The published results are difficult to evaluate (H.S.).]

Singh, K. B., Rao, P. S.: "Studies on the polycystic ovaries of rats under continuous auditory stress." *Am. J. Obstet. Gynecol.* **108**: 557-564 (1970). G78,701/70

In rats, continuous auditory stress can produce polycystic ovaries with inhibition of corpus luteum formation, thereby interfering with *reproduction*.

Jatho, K., Hellmann, H.: "Zur Frage des Lärm- und Klangtraumas des Orchester-musikers" (The problem of acoustic trauma in orchestra musicians). *H.N.O. (Berlin)* **20**: 21-29 (1972). J17,046/72

Effect of audiogenic stress upon professional musicians.

Byshevsky, A. S., Babich, V. P., Danilchenko, E. V.: "The mechanism of increase of blood coagulation at the early periods following sonic action." *Patol. Fiziol. Eksp. Ter.* **16** No. 6: 73-74 (1972) (Russian).

H79,323/72

In rats, exposure to intense sound decreased *antithrombin* activity within five minutes and thromboplastin activity much later and to a lesser extent. Activation of antithromboplastin was also of short duration.

Singh, K. B.: "Effects of sound on the female reproductive system." *Am. J. Obstet. Gynecol.* **112**: 981-991 (1972).

G89,061/72

Review on the effect of prolonged and intense sound upon the female *reproductive system* of various mammals. In accordance with the "hypophyseal-shift" theory, this stressor tends to diminish fertility through decreased gonadotropin production, resulting in ovarian atrophy. Pregnancy may also be disturbed.

Maass, B., Jacobi, E., Esser, G.: "Thrombozytenadhäsivität unter Lärmeinwirkung" (Thrombocyte adhesiveness during noise). *Dtsch. Med. Wochenschr.* **98**, 2153-2155 (1973). H78,870/73

Various forms of auditory stress increase *thrombocyte adhesiveness* and may thereby predispose to thrombosis in man (27 refs.).

Bell, R. W., Nitschke, W., Bell, N. J., Zachman, T. A.: "Early experience, ultra-

sonic vocalizations, and maternal responsiveness in rats." *Dev. Psychobiol.* **7**: 235-242 (1974).

J12,730/74

Exposure to cold and several other stressors induces ultrasonic *vocalization* in neonatal rats and consequent agitation in their mothers. "If the pup is mildly stressed he displays a pattern of ultrasonic signaling which elicits adaptive maternal responsiveness. If the pup is too severely stressed he displays persistent signaling which agitates the mother, preventing an adaptive pattern of behavior, and resulting in a prolonged response to stress in the pup."

+Genetics. Bevan, W.: "Sound-precipitated convulsions: 1947 to 1954." *Psychol. Bull.* **52**: 473-504 (1955). D78,855/55

Review on genetic and stress factors causing audiogenic convulsions. It is deplored that "despite general preference for a physiological model, nothing has been done to assay systematically physiological differences among susceptible and nonsusceptible animals. Although electroshock convulsions have been discussed within the framework of Selye's adaptation syndrome hypothesis, and although audiogenic seizures have been regarded as a stress phenomenon by both physiologically and psychologically biased investigators, no vigorous attempt to exploit Selye's logic has been made for the latter phenomenon" (145 refs.).

Anthony, A.: "Effects of noise on eosinophil levels of audiogenic-seizure-susceptible and seizure-resistant mice." *J. Acoust. Soc. Am.* **27**: 1150-1153 (1955). E80,679/55

"A prolonged eosinopenia occurs with several successive noise bursts—at a moderately low level (*ca* 250 eosinophils/cu mm blood) in seizure-resistant mice and at lower levels (*ca* 100 eosinophils/cu mm blood) in mice which experience convulsions during treatment. It was concluded that noise stimulation acts as a mild stress stimulus and is harmful only when it results in the production of fatal convulsions."

Anthony, A.: "Changes in adrenals and other organs following exposure of hairless mice to intense sound." *J. Acoust. Soc. Am.* **28**: 270-274 (1956). E82,034/56

On the basis of observations in hairless mice, it was concluded that both immobilization and intense sound vibrations on the skin surface can act as stressors. When the sound is very intense, the systemic response is similar to that seen after skin burns. Here, heat

and not sound is considered to be the responsible stressor.

Weltman, A. S., Sackler, A. M.: "Timidity and metabolic elimination patterns in audiogenic-seizure susceptible and resistant female rats." *Experientia* **22**: 627-629 (1966).

G16,051/66

There is a positive relationship between timidity and seizure susceptibility in rats exposed to "auditory stress." The rats also demonstrate an increase in diuresis and the quantity of feces.

Weltman, A. S., Sackler, A. M., Owens, H.: "Effects of levels of audiogenic-seizure susceptibility on endocrine function of rats." *Physiol. Behav.* **3**: 281-284 (1968).

H5,154/68

Rats susceptible to audiogenic seizures developed adrenal hypertrophy and thymus involution upon exposure to the stressor effect of an alarm bell.

Roth, T., Kramer, M., Trinder, J.: "The effect of noise during sleep on the sleep patterns of different age groups." *Can. Psychiatr. Assoc. J.* **17**: SS197-SS201 (1972).

H79,724/72

EEG, electromyographic and electrooculographic recordings indicate that noise of moderate intensity has little effect upon the sleep patterns of twenty-five-year-old subjects but causes increasingly more disturbance with progressing age.

Poirel, C., Bouten, F., Hengartner, O.: "Analyse chronobiologique des rythmes circadiens de la crise audiogène chez la souris Swiss/Albinos (Rb)" (Chronobiologic analysis of the circadian rhythms of audiogenic seizure in the Swiss/Albinos [Rb] mouse). *Ann. ACFAS* **40**: 128 (1973).

H87,899/73

In mice genetically predisposed to audiogenic seizures, the mathematical relationship of the seizures to the circadian rhythm has been analyzed.

Hallbäck, M., Folkow, B.: "Cardiovascular responses to acute mental 'stress' in spontaneously hypertensive rats." *Acta Physiol. Scand.* **90**: 684-698 (1974).

J13,405/74

Genetically hypertensive rats showed more pronounced cardiovascular responses to the stressor effect of sound than normotensive controls or renal hypertensive rats of a normal strain. Hence, the hyperreactivity is genetically conditioned.

Redgate, E. S.: "Neural control of pituitary adrenal activity in cyprinus carpio." *Gen. Comp. Endocrinol.* **22**: 35-41 (1974).

H81,914/74

"The prompt responses of plasma cortisol concentration to stimuli, such as sound, hypothalamic stimulation, the photoperiod, and restraint, indicate that the pituitary adrenal system of the carp is controlled by neural pathways in the brain of this teleost."

+Varia. Lazovik, A. D., Patton, R. A.: "The relative effectiveness of auditory stimulation and *motivational stress* in precipitating convulsions associated with magnesium deficiency." *J. Comp. Physiol. Psychol.* **40**: 191-202 (1947).

B26,573/47

Józkiewicz, S., Stanosek, J., Gregorczyk, J., Krzoska, K., Lewandowska-Tokarz, A.: "Über den Einfluss der chronischen Einwirkung von Lärm und Vibrationen niedriger Frequenzen auf die Zusammensetzung des Blutes, das relative Gewicht einiger Organe sowie den Gehalt der Askorbinsäure in den Nebennieren bei Meerschweinchen" (The influence of the chronic effects of noise and low frequency vibrations on the blood composition and the relative weight of several organs, as well as the ascorbic acid content of the adrenals in the guinea pig). *Acta Biol. Med. Ger.* **13**: 331-335 (1964).

F25,307/64

In guinea pigs, noise and *vibration* caused adrenal ascorbic acid depletion, especially when applied in combination. The change is ascribed to the G.A.S.

Anderson, T. A., Geber, W. F.: "Combined effects of chronic audio-visual stress and thiouracil administration on the cholesterol-fed rat." *J. Cell. Comp. Physiol.* **66**: 141-146 (1965).

G35,191/65

In rats, audiovisual stress can be produced by various bells, buzzers and white noise generators in addition to interrupted intense *illumination*. This may influence the atherogenic effect of thiouracil and high cholesterol diets.

Constanta, A., Contulesco, A., Ionesco, G., Miclesco-Groholsky, S.: "Recherches sur l'activité des transaminases et de la phosphatase acide dans l'agression sonore et vibratoire industrielle" (The activity of transaminases and acid phosphatase in the stress of industrial noise and vibration). *Arch. Mal. Prof.* **32**: 647-652 (1971).

G98,066/71

An increase in serum phosphatase and transaminase occurred in workers of a metal-

lurgical plant exposed to considerable noise and vibration. This increase is claimed to be characteristic of stress.

Sommer, H. C., Harris, C. S.: "Combined effects of noise and vibration on mental performance as a function of time of day." *Aerospace Med.* **43**: 479-482 (1972).

J16,970/72

In dogs, "emotional stress produced by firing a gun increased heart rate, cardiac output, and left ventricular work." The responses were reduced by propranolol and practolol, and abolished by alprenolol.

Hadjiolova, I.: "Veränderungen des Plasma- und Nebennierenrindencorticosterons bei Ratten während Hypokinesie und zusätzlicher Stress-Einwirkungen" (Influence of hypokinesia and subsequent stress upon the rat plasma and adrenal corticosterone level). *Int. Arch. Arbeitsmed.* **33**: 59-70 (1974). J17,473/74

Studies on plasma and adrenal corticosterone in rats exposed to different stressors

(heat, restraint, noise) alone or in combination. "A moderate increase in the levels of both plasma and adrenal corticosterone was observed after 24 hrs of hypokinesia. In a subsequent period of 60 days the corticosterone levels did not differ significantly from the levels found in the control animals. However, a marked decrease in adrenal weight and a slighter response to additional thermal stress were demonstrated after 60 days of hypokinesia. Differences between the restrained and the control animals were also found in the adaptation to chronic auditory stress."

Poulton, E. C., Edwards, R. S.: "Interactions and range effects in experiments on pairs of stresses: mild heat and low-frequency noise." *J. Exp. Psychol.* **102**: 621-628 (1974). J17,212/74

Review of the literature on the interaction between the stressor effects of heat and noise in man.

Wells, A., Jones, A., Williams, M., Geist, C. R.: "Noise, vitamin A deficiency, and emotional behavior in rats." *Percept. Mot. Skills* **38**: 392-394 (1974). J17,474/74

In rats, aversive stimulation (noise) appears to have a greater effect during food deprivation or vitamin A deficiency than otherwise.

Ultrasound, Sonic Booms

(See also Aerospace in the section on Occupations)

In guinea pigs exposed to ultrasound, morphologic changes typical of the G.A.S. develop quite readily.

In people exposed to repeated simulated sonic booms, stress manifestations have been surprisingly inconspicuous under the experimental conditions employed up to now.

Occasional exposure to sonic booms had no remarkable effect upon either the reproduction of minks or the ability of chicken eggs to be hatched.

Ultrasound, Sonic Booms

(See also our earlier stress monographs, p. xiii)

Introna, F.: "Ricerche sperimentali sulla patologia da ultrasuoni" (Experimental research on the pathology of ultrasound). *Med.-Leg. Assicur.* **1**: 13-42 (1953).

C4,806/53

In guinea pigs exposed to ultrasound, morphologic changes occur in various tissues, and particularly in mesenchymal tissue, similar to those "described by Selye in the condition of stress." In view of the occupational

exposure of various people to ultrasound, these findings have legal as well as medical significance.

Debijadji, R., Perovic, L., Varagic, V.: "Evaluation of the sympatho-adrenals activity in pilots by determination of urinary catecholamines during supersonic flight." *Aerosp. Med.* **41**: 677-679 (1970).

J21,924/70

Observations on supersonic pilots "indicate that stress reactions to flight conform to the General Adaptation Syndrome pattern."

Filcescu, V.: "Aspecte de fiziologie și fizioterapie ale zborului supersonic" (Aspects of physiology and physiopathology of supersonic flight). *Fiziol. Norm. și Pat.* **17**: 143-150 (1971) (Roumanian). J20,646/71

Thackray, R. I., Touchstone, R. M., Jones, K. N.: *The Effects of Simulated Sonic Booms on Tracking Performance and Autonomic Responses*, p. 15. Washington, D.C.: Federal Aviation Administration pamphlet, 1971. G85,874/71

In subjects exposed to four simulated indoor sonic booms over approximately thirty minutes, no evidence of performance impairment was found in two-dimensional compensatory tracking tasks. "Rather, performance improved significantly following boom stimulation along with heart-rate deceleration and skin conductance increase. The obtained pattern suggests that the simulated booms may have elicited more of an orienting or alerting response than a startle reflex."

Smith, R. C., Hutto, G. L.: *Sonic Booms and Sleep: Affect Change as a Function of Age*, p. 11. Washington, D.C.: Federal

Aviation Administration pamphlet, 1972.

G98,578/72

Subjects aged twenty-one to seventy-two years spent twenty-one consecutive nights in a sleeping room where they were exposed hourly to simulated sonic booms of moderate intensity. The noise had no significant effect as judged by answers to a composite mood adjective questionnaire.

Collins, W. E., Iampietro, P. F.: *Simulated Sonic Booms and Sleep: Effects of Repeated Booms of 1.0 PSF*, p. 27. Washington, D.C.: Federal Aviation Administration pamphlet, 1972. J4,892/72

Males aged twenty-one to seventy-two years were exposed hourly to simulated sonic booms during 21 consecutive nights. As judged by various physiologic indicators (EEG, muscle tone, REM sleep) "the changes in sleep appear roughly comparable to what might occur in response to the noise of a passing truck at 40-45 dBA" (32 refs.).

Thackray, R. I., Touchstone, R. M., Bailey, J. P.: "Behavioral, autonomic, and subjective reactions to low- and moderate-level simulated sonic booms: a report of two experiments and a general evaluation of sonic boom startle effects." Federal Aviation Administration, Aviation Med. pamphlet, pp. 1-14. Washington, D.C., 1974. J19,035/74

Brewer, W. E.: "Effects of noise pollution on animal behavior." *Clin. Toxicol.* **7**: 179-189 (1974). J13,847/74

Under the conditions of these experiments, occasional exposure to sonic booms had no severe effect upon either reproduction in minks or the ability of chicken eggs to be hatched.

Ionizing Rays

Observations on various species suggest that the radiation syndrome is very similar to the alarm reaction of the G.A.S. However, the thymic lymphatic involution is particularly pronounced, and the characteristic symptoms of x-ray injury (especially the bone marrow damage) are much more prominent than those resulting from exposure to other stressors. In view of the severe malfunctioning of the hemopoietic apparatus, the typical stress-induced polymorphonuclear leukocytosis is not only lacking but is replaced by leukopenia.

A very characteristic effect of x-irradiation is a phenomenon strikingly similar to premature aging. This model has been successfully used for many studies on the mechanism of aging, although it is still debatable whether the manifestations of x-irradiation are strictly comparable to those of natural aging.

+Varia. The effect of ionizing rays upon the action of various other agents has been the subject of innumerable studies, especially in relation to aerospace medicine, where cosmic radiation in space is always a danger and may affect hypoxia, changes in gravity, and other factors that confront the astronaut. The voluminous literature on the effect of exposure to cold or artificial hibernation upon x-ray resistance is quite contradictory and virtually impossible to evaluate.

"Electroshock stress" before x-irradiation does not significantly affect the survival of rats, but if applied afterwards, actually decreases resistance to this as well as to other stressors.

The adrenocortical changes of the alarm reaction produced by infection with *Salmonella*, and those of x-irradiation, are additive if the two stressors are applied concurrently. However, it has also been claimed that under certain conditions stressors can increase x-ray resistance.

Ionizing Rays

(See also our earlier stress monographs, p. xiii)

Generalities. Dougherty, T. F., White, A.: "Pituitary-adrenal cortical control of lymphocyte structure and function as revealed by experimental X-radiation." *Endocrinology* **39**: 370-385 (1946).

95,612/46

"CBA mice, 60 to 80 days old, received total body X-radiation. A large dose of X-rays, 200 r, produced within 3 hours a lymphopenia, tissue lymphocyte degeneration, and total serum protein and gamma globulin increases. These changes also occurred in 1 day postoperative adrenalectomized mice receiving 200 r. This dose gave an anamnestic response in previously immunized mice in the absence of the adrenals." Smaller x-ray doses were effective in intact but not in adrenalectomized mice, presumably because the action is partially mediated through the pituitary-adrenal axis.

Kohn, H. I.: "Changes in blood plasma of guinea-pig during acute radiation syndrome." *Am. J. Physiol.* **162**: 703-708 (1950).

B49,916/50

Observations on guinea pigs suggest that the radiation syndrome is similar to the alarm reaction of the G.A.S., yet certain differences show that the two conditions are not identical.

Mole, R. H.: "Whole body irradiation and the idea of stress." *Br. J. Exp. Pathol.* **37**: 528-531 (1956).

C26,307/56

Summary of personal observations and published data suggesting that certain

phenomena that were formerly thought to be due to nonspecific stress are "physiological consequences of cell death, a specific effect of irradiation . . . as soon as mechanisms are investigated in detail it would appear that the nonspecific response is really the sum of specific responses. Somatic stress is compounded of specific responses to starvation, dehydration, cell death and so on, just as shock is compounded of specific responses to blood and fluid loss, infection, pain and psychic disturbance. Some of these specific responses may share final common paths, and one of these may be adrenal activity, but when the specific responses are abstracted there may be nothing left of a general syndrome which needs explanation in nonspecific terms."

Gorizontov, P. D., Grafov, A. A., Shakhodyrov, V. V.: "The question of the role of the pituitary-adrenal system in the development of some manifestations in experimental radiation disease." *Vestn. Akad. Med. Nauk SSSR* **13**: 12-21 (1958) (Russian).

D2,825/58

Extensive review on ionizing radiation as a stressor agent.

Scholz, H.: "Die Behandlung des Bestrahlungssyndrom mit Prednisolon" (Treatment of the radiation syndrome with prednisolone). *Zentralbl. Gynäk.* **81**: 1065-1075 (1959).

C78,296/59

Review of the literature and personal observations suggest that the radiation syndrome is essentially related to the G.A.S. and associated with adrenocortical deficiency. Prednisolone allegedly exerts a therapeutic

effect both on the generalized radiation syndrome and on local x-ray damage.

Fridrich, R.: "Beitrag zur zentral-nervösen Beeinflussung des Strahlensyndroms" (Contribution on central nervous system mediation in the radiation syndrome). *Radiol. Clin. Biol.* **34**: 78-82 (1965). J23,648/65

In rats sensitized with lead acetate, minute doses of bacterial endotoxin sufficed to cause death. With this technique it could be demonstrated that after x-irradiation endotoxin is absorbed into the blood. Hence, endotoxemia probably plays an important role in the irradiation syndrome.

→Varia. Berliner, D. L., Stevens, W., Berliner, M. L.: "The effects of ionizing radiation on the biosynthesis and biotransformation of corticosteroids." *Proc. Int. Symp. Effects Ionizing Radiat. Reprod. Syst., Colorado 1962*, pp. 433-449 (1963). G11,813/63

X-radiation increases blood *corticoids*, as do other stressors. The literature on this subject, and particularly on the effect of ionizing rays upon the biosynthesis and metabolism of corticoids, is reviewed (55 refs.).

Tobias, P. R.: "The effects of radiation on integrated behavior." In: Burns, N. M., Chambers, R. M. et al., *Unusual Environments and Human Behavior*, pp. 395-417. Glencoe, Ill.: Free Press, 1963. E10,434/63

In various species of animals traveling on

satellite spaceships, exposure to x-rays, acceleration and vibration considerably diminished the blood 5-HT content.

Lucas, D. R., Peakman, E. M.: "Ultrastructural changes in lymphocytes in lymph nodes, spleen and thymus after sublethal and supralethal doses of X-rays." *J. Pathol.* **99**: 163-169 (1969). G72,305/69

The EM changes induced by ionizing irradiation in the *lymphocytes* of various lymphatic organs are described and well illustrated.

Polis, B. D., Polis, E., DeCani, J., Schwarz, H. P., Dreisbach, L.: "Effect of physical and psychic stress on phosphatidyl glycerol and related phospholipids." *Biochem. Med.* **2**: 286-312 (1969). G65,013/69

In rats exposed to ionizing radiation or "acceleration stress," the plasma concentration of *phosphatidylglycerol* was consistently increased. "Extension of the studies to humans stressed by acceleration to grayout, sleep deprivation, schizophrenia, combat, etc., revealed that all stresses were accompanied by significant increments in plasma phosphatidyl glycerol." In rats, hypophsectomy prevented the increase in phosphatidylglycerol induced by acceleration stress, but a rise in the brain level of this compound remained even in the absence of the pituitary.

Lundin, P., Järplid, B.: "Effects of corticosteroid and radiation on lymphoid tissue in mice. Comparisons and mutual interactions." *Lymphology* **6**: 158-166 (1973).

J7,450/73

In mice, similar degrees of *thymus involution* were produced by x-rays and prednisolone. "After steroid treatment the lymphocytolysis in the lymph nodes, spleen and the Peyer's patches was most marked in the germinal centres whereas the so-called thymic dependent areas were mainly preserved. After irradiation compared to steroid-treatment the cytology was definitely more pronounced in all parts of these lymphoid tissues, including the white pulp of the spleen, the whole follicles and the subcapsular parts of the lymph node cortex and the follicles and partially the interfollicular areas of the Peyer's patches. From the time of the first regeneration of the thymic cortex after irradiation, steroid sensitive cells could be found in all lymphoid tissues, indicating that the pool of these cells regenerates rapidly after irradiation." These changes are related

to the classic lymphocytolysis and thymic involution of the alarm reaction.

"Electroshock stress" applied before x-irradiation does not affect the survival rate of rats but decreases the survival rate if

applied afterwards. The same is true of the stress of being shipped to the laboratory.

Gambino, J. J., Bennett, L. R., Billings, M. S., Lamson, B. G.: "Biological effect of stress following ionizing radiation." *Aerosp. Med.* **35**: 220-224 (1964). G9,697/64

Review of the literature on the effect of hypothermia upon x-ray resistance. Rats given a single dose of 500 rads (total body irradiation) showed "reduced longevity; retarded growth; cataracts; accelerated onset of skin ulcers, greying, enlarged mammary glands and palpable tumors; and increased incidence of palpable tumors." Repeated exposure to brief periods of cold did not significantly influence these changes, with the possible exception of tumorigenesis (41 refs.).

Musacchia, X. J., Barr, R. E.: "Helium-cold induced hypothermia in the hamster and radio-resistance." *Physiologist* **10**: 257 (1967). F86,700/67

In hamsters rendered hypothermic by being placed in an 80 percent helium-20 percent oxygen atmosphere at low temperatures, resistance to cobalt irradiation is increased.

Reinhardt, K.: "Bestrahlung, insbesondere Lokal- und fraktionierte Bestrahlung in Hypothermie bei der Ratte" (Irradiation, especially local and fractionated irradiation, during hypothermia in rats). *Strahlentherapie* **132**: 274-283 (1967). G45,682/67

In rats, induced hypothermia protects against local and whole body x-irradiation.

Phillips, R. D., Kimeldorf, D. J.: "Effect of x-irradiation on the resistance of rats to low temperature." *Fed. Proc.* **27**: 508 (1968). H565/68

In rats exposed to cold after whole body x-irradiation, survival time was diminished.

Phillips, R. D., Kimeldorf, D. J.: "An immediate irradiation effect on resistance of rats to low temperature." *J. Appl. Physiol.* **24**: 768-772 (1968). G58,748/68

X-irradiation has a detrimental effect on the survival of rats upon exposure to cold.

Vácha, J., Pospíšil, M.: "Individual differences in the stress response of mice and their relationship to the differences in radiation tolerance." *Med. Exp. (Basel)* **19**: 58-63 (1969). H17,170/69

In mice, pretreatment with various stressors (*starvation, isolation*) increases x-ray tolerance, but only if the stress produced is of moderate intensity.

Kurasz, S., Musiatowicz, B., Borzuchowska, A., Swiderska, K.: "Histologische und histochemische Veränderungen in der Nebennierenrinde des Kaninchens nach experimenteller Infektion mit *Salmonella typhimurium* und Bestrahlung" (Histologic and histochemical changes in the adrenal cortex of rabbits after experimental infection with *Salmonella typhimurium*, and irradiation). *Zentralbl. Bakter. [Orig. A]* **224**: 463-471 (1973).

J11,180/73

In rabbits, *infection* with *Salmonella typhimurium* plus x-irradiation produces adrenocortical changes characteristic of the alarm reaction. These are more intense following exposure to both agents than after application of either of them alone.

Warren, S., Chute, R. N., Porter, M. W.: "The effect of *parabiosis* on life-span of rats stressed by radiation." *J. Gerontol.* **30**: 15-21 (1975).

J19,637/75

Light Rays

The circadian rhythm differs in various species. Thus, the eosinophil count reaches a maximum in man and a minimum in mice at about 03:00. The reverse is true between 14:00 and 17:00. Yet, in both species, intense light causes eosinopenia at all times; this has been ascribed to the alarm reaction.

In rats exposed to constant strong light, polycystic ovaries and continuous vaginal estrus may develop concurrently with the typical adrenal hypertrophy of the stress response. In mice, the blood corticosterone levels reach a peak in the winter with a nadir in the spring and summer. Differences in lighting have been alleged to play a role in this circannual rhythm.

In women, strong light raises urinary catecholamine excretion, presumably as a result of stress.

F17,971/64

The blood eosinophil count reaches a maximum in man and a minimum in mice at about 03:00. The reverse is true between 14:00 and 17:00. In both species, intense light causes eosinopenia at all times; this is ascribed to the stressor effect and the resulting alarm reaction.

Anderson, T. A., Geber, W. F.: "Combined effects of chronic audio-visual stress and thiouracil administration on the cholesterol-fed rat." *J. Cell. Comp. Physiol.* **66**: 141-146 (1965).

G35,191/65

In rats, audiovisual stress can be produced by various bells, buzzers and white noise generators in addition to interrupted intense illumination. This may influence the atherogenic effect of thiouracil on high-cholesterol diets.

Singh, K. B.: "Induction of polycystic ovarian disease in rats by continuous light. I. The reproductive cycle, organ weights, and histology of the ovaries." *Am. J. Obstet. Gynecol.* **103**: 1078-1083 (1969).

G65,765/69

In rats exposed to constant light, persistent vaginal estrus and atrophic polycystic ovaries developed in combination with adrenal hypertrophy. These changes were ascribed to stress [although a specific effect was not eliminated (H.S.).]

Kamchatnov, V. P.: "Effect of working in red light on development of fatigue." *Ind. Med. Surg.* **38**: 445-447 (1969).

J15,917/69

"Persons working in red light show a sharp decrease in working ability compared with persons working in normal lighting, and this may evidently explain their greater proneness to fatigue."

Haus, E., Halberg, F.: "Circannual rhythm in level and timing of serum corticosterone in standardized inbred mature C-mice." *Environ. Res.* **3**: 81-106 (1970).

G73,872/70

In mice, blood corticosterone levels are highest during winter and lowest during

spring and summer. The circadian rhythm likewise varies during the phases of the circannual cycle. Lighting plays an important role in these changes, although the mechanism of its effect is not yet clear (95 refs.).

Meduri, R., Puddu, P., Descovich, G. C., Rimondi, S.: "Variazioni delle catecolamine urinarie dopo stimolazioni luminose policromatiche e di grande lunghezza d'onda (Nota Prima)" (Urinary catecholamine variations after stimulation with polychromatic light of long wavelength [First Note]). *Ann. Ottal.* **97**: 635-649 (1971). J1,616/71

In women exposed to strong polychromatic light urinary catecholamine excretion was increased, presumably as a result of stress.

Mos, L., Vriend, J., Poley, W.: "Effects of light environment on emotionality and the endocrine system of inbred mice." *Physiol. Behav.* **12**: 981-989 (1974). J13,743/74

Mice of different strains were reared in either a dark or a light environment. "Strain and sex affected all organ weights, light rearing affected adrenal, spleen and ovary weight, and emotionality testing affected pituitary and adrenal weight. The results were interpreted that light rearing affects maturation of the hypothalamic-pituitary-adrenal axis and response to stress."

Ultraviolet Rays

Very little work has been done on the stressor effect of ultraviolet rays, but allegedly, they can enhance the development of restraint-induced ulcers in the rat.

Ultraviolet Rays

(See also our earlier stress monographs, p. xiii)

Dumas, J., Péres, G.: "Action du rayonnement ultraviolet sur la formation de l'ulcère de contrainte chez le rat blanc" (Action

of ultraviolet irradiation on the formation of restraint ulcer in the white rat). *C.R. Acad. Sci. (Paris)* **163**: 863-865 (1969).

H19,005/69

Ultraviolet irradiation accelerates the development of stress ulcers by restraint in the rat.

Vibration

Exposure to strong vibrations can act as a powerful stressor. This effect has been studied especially in connection with problems of aerospace medicine and industrial work.

→**Hormones.** In monkeys, simulated "space stressor conditions," such as vibration, centrifugation and isolation with restraint, caused a rise in catecholamine and a fall in

17-KS excretion, with a diminution of diuresis. On the other hand, in rats, "vibratory stress" allegedly increased urinary 17-KS and corticoid elimination; this was accompanied by thymus atrophy. As we have pointed out before, 17-KS excretion is difficult to interpret because it may indicate corticoid or testoid elimination, a rise in the former and a fall in the latter being characteristic of stress. Increased catecholamine elimination and thymus atrophy are indubitably stress indicators. Yet, in man, certain types of sinusoidal vibration have been claimed to diminish plasma and urinary corticoid levels, while causing clinically manifest signs of stress and intense discomfort. These observations are difficult to interpret.

In dogs, even under light pentobarbital anesthesia, whole body vibration does raise the 17-OHCS plasma level, although not as much as in unanesthetized animals. Evidently, emotional factors are important, but not indispensable, for this response. In dogs, horizontal whole body vibration increased 17-OHCS and EP, but not 5-HT and NEP concentrations in plasma. In man, after repeated exposure to mechanical vibration of low frequency, the initial rise in plasma catecholamine and blood sugar content tends to diminish, whereas an increase in plasma cortisol levels usually persists without any evidence of adaptation.

In workers occupationally exposed to strong vibrations, blood cortisol and urinary VMA elimination "indicates a strong stress response."

→**Varia.** Among other changes possibly related to vibration, special attention was given to the atrophy of the thymicolymphatic apparatus, adrenal hypertrophy with a fall in its ascorbic acid content, rises in serum aldolase and lactic dehydrogenase, as well as psychoneurologic alterations.

+**Varia.** Several publications have attempted (with moderate success) to distinguish between the stressor effect of vibration and that of other concurrent stimuli common in space, industry and so on. Apparently, male rats are more sensitive than females to the typical adrenal enlargement, thymicolymphatic and gonadal atrophy, as well as the loss of weight caused by vibration.

→**Hormones.** Winters, W. D.: "Various hormone changes during simulated space stresses in the monkey." *J. Appl. Physiol.* **18**: 1167-1170 (1963). E35,060/63

In *Macaca nemestrina* monkeys, urinary excretion of 17-KGS and catecholamines as well as diuresis were examined under simulated space stressor conditions, namely centrifugation, vibration and isolation with restraint. The results varied with the type of stressor used, but a reduction in urine volume was obvious in all instances. "A fall in steroid and slight elevation in catecholamine excretion were observed following vibration and centrifugation. The centrifugation ap-

peared to be slightly more stressful. Isolation with restraint appears to be a severe stress to the animals as demonstrated by a marked elevation of amine and a marked reduction in both urine output and steroid excretion."

Weltman, A. S., Sackler, A. M., Owens, H., Bernstein, M.: "Effects of vibration on the endocrine system of male rats." *Am. Zoolgist* **3**: 526 (1963). E59,922/63

In rats, "vibratory stress" caused an increase in urinary 17-KS and corticoids, as well as thymus atrophy.

Litta-Modignani, R., Blivaiss, B. B., Magid, E. B., Priede, I.: "Effects of whole-body vibration of humans on plasma and urinary corticosteroid levels." *Aerospace Med.* **35**: 662-667 (1964). G18,097/64

Exposure of men to sinusoidal vibration by means of a Western Gear Mechanical Shake Table in a modified jet aircraft seat produced—contrary to expectations—a decrease in plasma and urinary corticoids. "The vibration gave a rather dramatic general discomfort associated frequently with dyspnea, chest pain, abdominal pain, and in some cases, the experiment had to be interrupted for this reason. Such a combination of symptoms is characteristic of stress response which is usually associated with an increase in plasma 17-OH-CS" (43 refs.).

Korukaev, I. S.: "Plasma 17-hydroxycorticosteroids in patients with vibration sickness." *Gig. Tr. Prof. Zabol.* **8** No. 3: 7-10 (1964). Transl. Sup.: *Fed. Proc.* **24**: 253-254 (1965) (English translation; Russian original). F33,746/65

Industrial workers exposed to chronic vibration developed a typical stress syndrome with increased blood 17-OHCS.

Blivaiss, B. B., Litta-Modignani, R., Galansino, G., Foa, P. P.: "Endocrine and metabolic response of dogs to whole body vibration." *Aerospace Med.* **36**: 1138-1144 (1965). F75,989/65

In dogs, horizontal whole body vibration produced an increase of 17-OHCS and EP but not of 5-HT or NEP in plasma. This response persisted but was less severe under pentobarbital anesthesia.

Litta-Modignani, R., Magid, E. B., Blivaiss, B. B.: "Effects of whole body vibrations of humans on plasmatic and urinary corticosteroid levels." In: Martini, L. and Pecile, A., *Hormonal Steroids. Biochemistry, Pharmacology, and Therapeutics*, Vol. 2, pp.

517-525. New York and London: Academic Press, 1965. E5,496/65

In man, vibrations of a sinusoidal nature performed by a mechanical shake table that attempts to imitate conditions in a jet aircraft seat did not cause any increase in plasma 17-OHCS but rather a small decrease. A slight diminution was also found in urinary blue-tetrazolium-reducing steroids (BTS) and 17-KGS. Under these moderate conditions of vibration, "a mild inhibition of the hypothalamic-hypophysis-adrenal axis could have occurred."

Blivaiss, B. B., Litta-Modignani, R., Priede, I.: "Plasma 17-hydroxycorticosteroids in dogs after whole body vibration." In: Martini, L. and Pecile, A., *Hormonal Steroids. Biochemistry, Pharmacology, and Therapeutics*, Vol. 2, pp. 511-516. New York and London: Academic Press, 1965.

E5,495/65

In dogs anesthetized with pentobarbital, whole body vibration still causes a "stress-like response" in that it increases plasma 17-OHCS; this reaction is more pronounced in nonanesthetized animals. Evidently, emotional factors are important but consciousness is not indispensable for typical adrenal stress reactions.

Parin, V. V., Antipov, V. V., Raushenbakh, M. O., Saksonov, P. P., Shashkov, V. S., Chernov, G. A.: "Changes in blood serotonin level in animals exposed to ionizing radiation and dynamic factors of space flight." *Fed. Proc.* **25**: T103-T106 (1966).

F60,935/66

In various species of animals traveling on satellite spaceships, exposure to x-rays, acceleration and vibration considerably diminished the blood 5-HT content.

the limbic system and hypothalamus." *Neuroendocrinology* **2**: 157-174 (1967).

F88,389/67

Rats exposed to intermittent air blasts developed thymus involution and a pronounced increase in plasma corticosterone and pituitary ACTH levels. Lesions in various locations of the limbic system and hypothalamus blocked these effects independently of each other, indicating that different mechanisms are involved in their production.

Compression, Decompression

The stressor effect of compression and decompression is of special clinical interest in connection with diving and orbital flights. Several observations confirm that these agents can produce clearcut manifestations of stress, as might have been expected.

Compression, Decompression

(See also our earlier stress monographs, p. xiii)

Smith, D. C., Brown, F. C.: "Effects of acute decompression stress upon some blood components, especially leucocytes, in intact

and splenectomized cats." *Am. J. Physiol.* **164**: 752-765 (1951). B56,267/51

In normal and splenectomized cats, "decompression stress" produced an initial increase in blood lymphocytes followed by a decrease to subnormal levels. The number of neutrophils rose in both intact and splenec-

tomized cats submitted to this stressor. Changes in eosinophil counts were difficult to interpret because of great individual variations.

Gravity

The so-called gravitational stress has been studied in experimental animals and man, especially in relation to actual or simulated space flights and centrifugation. Weightlessness as such does not appear to be a strong stressor, but intense acceleration or

deceleration does produce typical somatic manifestations of the stress syndrome. It is difficult, however, to distinguish clearly between the effects of changes in gravity as such and associated phenomena such as vibration, emotional excitement and several environmental factors. Under various conditions of acceleration, deceleration, impact and centrifugation, the blood sugar, lactate, FFA and catecholamine levels do not always parallel each other.

J15,625/57

Studies on the catecholamine output of men exposed to centrifugation.

Goodall, McC., Berman, M. L.: "Urinary output of adrenaline, noradrenaline, and 3-methoxy-4-hydroxymandelic acid following centrifugation and anticipation of centrifugation." *J. Clin. Invest.* **39**: 1533-1538 (1960).

C92,945/60

Urinary excretion of catecholamines was accelerated in young men exposed to the "gravitational stress" of centrifugation. Catecholamine excretion was accelerated to a somewhat lesser extent by the mere anticipation of centrifugation. "Under high gravitational stress, increased adrenaline release seems to be largely related to the emotions,

while the noradrenaline release seems more closely related to the physical changes (hemodynamics and so forth) produced by centrifugation. Following the increased release of either or both adrenaline and noradrenaline, there is a commensurate rise in the urinary output of their common metabolic product, 3-methoxy-4-hydroxymandelic acid" (34 refs.).

Frankenhaeuser, M., Sterky, K., Jaerpe, G.: "Psychophysiological relations in habituation to gravitational stress." *Percept. Mot. Skills* **15**: 63-72 (1962). D46,292/62

In male medical students, gravitational stress (centrifugation) increased EP excretion without causing any pronounced change in NEP elimination or heart rate. After repeated centrifugation, adaptation occurred.

Goodall, M.: "Sympathoadrenal response to gravitational stress." *J. Clin. Invest.* **41**: 197-202 (1962). E41,813/62

EP excretion was increased in subjects before, during and immediately after centrifugation, presumably because of anxiety associated with the procedure. NEP output was elevated only during centrifugation and immediately afterwards. These changes "appeared to be dependent upon the physical stress imposed by centrifugation and had no direct relationship to the G tolerance of the subject."

Winters, W. D.: "Various hormone changes during simulated space stresses in the monkey." *J. Appl. Physiol.* **18**: 1167-1170 (1963). E35,060/63

In *Macacca nemestrina* monkeys, diuresis and urinary excretion of 17-KGS and catecholamines were examined under simulated space stressor conditions, namely centrifugation, vibration and isolation with restraint. The results varied with the type of stressor used, but reduction in urine volume was obvious in all instances. "A fall in steroid and slight elevation in catecholamine excretion was observed following vibration and centrifugation. The centrifugation appeared to be slightly more stressful. Isolation with restraint appears to be a severe stress to the animals as demonstrated by a marked elevation of amine and a marked reduction in both urine output and steroid excretion."

Bowman, R. E., Wolf, R. C.: "Plasma 17-OHCS response of the infant rhesus monkey to a noninjurious, noxious stimulus." *Proc. Soc. Exp. Biol. Med.* **119**: 133-135 (1965). F42,116/65

In two-day-old rhesus monkeys, centrifugation caused elevations in the nonconjugated 17-OHCS content of the plasma, but this effect was not as marked as that obtained with ACTH, "suggesting either that the restraint and rotation was not sufficiently stressful or that the infant CNS-hypophyseal axis was not sufficiently developed to stimulate fully the adrenal cortex."

Parin, V. V., Antipov, V. V., Raushenbakh, M. O., Saksonov, P. P., Shashkov, V. S., Chernov, G. A.: "Changes in blood serotonin level in animals exposed to ionizing radiation and dynamic factors of space flight." *Fed. Proc.* **25**: T103-T106 (1966).

F60,935/66

In various species of animals traveling on satellite spaceships, exposure to x-rays, acceleration and vibration considerably diminished the blood 5-HT content.

Foster, P., Sonntag, R. W. Jr.: "Urinary excretion of catecholamines and 17-hydroxycorticosteroids following +G_x impact in humans." *Aerospace Med.* **40**: 18-23 (1969).

H24,229/69

In humans, prior to both real and threatened impact in a decelerator, urinary NEP, EP, and 17-OHCS increased significantly. After impact, there was no change in NEP but EP levels rose fivefold over the controls, and 17-OHCS showed gradual but significant increases. There were no significant differences between the excretion rates in true and sham impacts with reference to 17-OHCS and NEP, but EP elimination was significantly higher following true impact. "Comparison of sham impact and actual impact data reveal that epinephrine is probably the mediator of the increased sympathetic activity associated with impact and that the threatened or actual exposure of a human to impact is more of a psychological than a physical stress."

Fluck, D. C., Salter, C.: "Effect of tilting on plasma catecholamine levels in man." *Cardiovasc. Res.* **7**: 823-826 (1973).

J8,857/73

In man, tilting of the body from a horizontal to a 30° position caused a significant rise in plasma EP and NEP, but both catecholamines approached the resting level after twenty-five minutes of tilting. Neither the pulse rate nor the blood pressure was affected. The change was ascribed to stress.

Arslan, M., D'Amelio, G., Marchiori, C.: "Clinical and endocrinological effects of cori-

olis accelerations and their behavior under drug treatment." *Acta Otolaryngol.* (Stockh.) **77:** 155-158 (1974). J12,116/74

Coriolis accelerations occur in subjects who make head movements during a body rotation at constant angular speed by provoking a flow of endolymph in the semicircular canals. This is associated with nausea, dizziness, pallor, sweat, vomiting, variations in pulse rate and arterial pressure, and a considerable rise in urinary catecholamine, 17-KS and 17-OHCS elimination. The authors conclude that "for normal subjects, exposure to Coriolis accelerations represents a stress which affects the adrenergic but not the hypophysial-cortical system. This stress is consistently related to the emotional tension originated by the test itself. The possibility of preventing the adrenergic hyperactivity of emotional origin by diazepam is discussed."

F81,569/67

As judged by changes observed after centrifugation, "increased liver glycogenesis in stressed rats was always preceded by an in-

crease in total synthetase activity due to an increase in the G-6-P independent form of the enzyme. No increase in liver glycogenesis or synthetase activity occurred in 14-day-old rats, in rats treated with actinomycin D or Metopirone, or in adrenalectomized rats."

Polis, B. D., Polis, E., DeCanis, J., Schwarz, H. P., Dreisbach, L.: "Effect of physical and psychic stress on phosphatidyl glycerol and related phospholipids." *Biochem. Med.* **2:** 286-312 (1969).

G65,013/69

In rats exposed to ionizing radiation or "acceleration stress," the plasma concentration of *phosphatidylglycerol* was consistently increased. "Extension of the studies to humans stressed by acceleration to grayout, sleep deprivation, schizophrenia, combat, etc., revealed that all stresses were accompanied by significant increments in plasma phosphatidyl glycerol." In rats, hypophrectomy prevented the increase in phosphatidylglycerol induced by acceleration stress, but a rise in the brain level of this compound persisted even in the absence of the pituitary.

Harrison, M. H.: "Adrenergic beta-receptor blockade and metabolic response to centrifugation stress." *J. Appl. Physiol.* **35:** 793-797 (1973).

J9,353/73

In men exposed to centrifugation stress, the β-adrenergic blocking agent oxprenolol curtailed the increase in FFA and tachycardia but had little effect on the raised glycerol levels. "It is concluded that increased norepinephrine secretion is responsible for the observed metabolic effects of centrifugation and that centrifugation-induced tachycardia is not a purely beta response."

Oyama, J., Chan, L.: "Oxygen consumption and carbon dioxide production in rats during acute centrifugation stress and after adaptation to chronic centrifugation." *Fed. Proc.* **32:** 392 (1973).

H67,544/73

In rats, continuous centrifugation causes a pronounced hypothermia and a decrease in the BMR. However, upon prolonged exposure to the stressor, when adaptation occurs, the BMR rises above normal. The authors conclude that "the principal factor responsible for the centrifugation stress-induced hypothermia in rats is a decrease in their rate of heat production."

C29.216/57

Personal aggressiveness was seen to be a significant factor in the gravity tolerance of men subjected to centrifugal stress, those individuals with outgoing and aggressive personalities proving definitely more resistant to centrifuge-induced blackout and loss of sight. Even among such better adapted individuals G tolerance varied according to the immediate psychologic state, so that they experienced "highest black-out levels just after they had expressed some anger, or were relatively free from anxiety. Lowest black-out levels were obtained when they were worried, depressed, anxious."

J12,120/74

In man, "after propranolol, the heart rate response to increased G at rest averaged 38% of that observed without blockade, indicating that G-induced cardioacceleration is predominantly due to sympathetic stimulation." However, subjective G tolerance was well preserved; hence, sympathetic chronotropic stimulation of the heart is not essential for the circulatory defense against gravitational stress.

Electricity, Electroschok

→**Hormones.** The production by electroschok of typical stress manifestations with adrenocortical activation has been amply demonstrated on the many patients who received this therapy for mental illness. The results have also been confirmed in experimental animals, showing that the hormonal response to electroschok is essentially the same as that produced by other acute stressors. However, in rats, electroschok (like starvation, hypoxia, surgical interventions and adrenalectomy) allegedly failed to produce a depletion of brain 5-HT and NEP, such as would be induced by swimming to exhaustion in cold water. These negative findings require confirmation, especially since in guinea pigs brain EP and NEP do drop considerably after electroschok. This effect is long-lasting and can be inhibited but not completely abolished by phenobarbital sedation. Electroschoks (like several other stressors) diminish insulin secretion in the rat. This has been ascribed to endogenous EP.

→**Varia.** In rats, repeated electroshocks caused considerable enlargement of the adrenals with an increase in their ascorbic acid and cholesterol content, gastric ulcer formation, and raised plasma FFA. Single shocks resulted in a drop in adrenal ascorbic acid and cholesterol.

Among the other effects described as characteristic of electroshock in rats are induced fighting behavior, a high incidence of dental caries, and myocardial damage.

+**Varia.** As previously stated, the stressor action of electroshock can be diminished, though rarely abolished, by various sedatives and tranquilizers. In schizophrenics, electroconvulsive therapy raises the plasma 17-OHCS level even when epileptic seizures are blocked by diphenylhydantoin.

On high-fat, high-cholesterol diets, periodic electroshocks caused marked hypercholesterolemia, hyperlipemia and a predisposition for coronary atherosclerosis in the rat. During the early neonatal period, electroshock fails to produce the usual ascorbic acid depletion and increase in adrenal corticosterone content in the rat, presumably because of an immaturity of the hypothalamic centers. However, these observations have not been confirmed by subsequent investigators, who were able to elicit obvious stress reactions in rats during the first five days of life. The production of gastric lesions by electroshock and cold is facilitated if the stressors are administered simultaneously.

Electroshock applied before x-irradiation does not affect the survival rate of rats but does shorten it if applied afterwards.

The genetically determined mouse-killing activity of certain strains of rats is blocked by chronic electroconvulsive shock therapy, and at the same time, brain NEP rises. Hunger and thirst did not affect the fighting behavior elicited by electroshock in rats. Handling during infancy caused only minor variations in the aggressiveness of rats exposed to electric footshock in adulthood.

Electricity, Electroshock

(See also our earlier stress monographs, p. xiii, and Neuropsychiatric Diseases of Adaptation)

Generalities. Sager, O., Badenschi, G., Cotăescu, E., Roth, R. R.: "Actiunea electroșocului asupra glandelor cu secreție internă" (Effects of electroshock on endocrine gland secretion). *Bull. Sci. Acad. R.P.R. Roumanie, Sci. Méd.* 2: 651-659 (1950). (Roumanian).

G99,776/50

In man, electroshocks produce increased ACTH secretion, eosinopenia and lymphopenia, reaching a maximum within about four hours. Repeated electroshocks may also cause menstrual disturbances in women and impotence in men. All these effects are ascribed to the G.A.S.

Reiss, M.: "Investigations of hormone equilibria during depression." In: Hoch, P. H. and Zubin, J., *Depression*. New York: Grune and Stratton, 1954.

J12,862/54

Electroshock administered to depressive patients increases corticoid production, presumably through stimulation of the hypothalamo-pituitary system.

Bliss, E. L., Migeon, C. J., Branch, C. H. H., Samuels, L. T.: "Reaction of the adrenal cortex to emotional stress." *Psychosom. Med.* **18**: 56-76 (1956).

C13,032/56

In normal people and psychiatric patients emotional stress (subjectively estimated by manifestations of anxiety and tension) whether occurring spontaneously or elicited experimentally, caused consistent but very modest increases in blood and urinary 17-OHCS. These changes were always much less pronounced than those produced by ACTH, Piromen, insulin, electroshock or moderate physical exercise.

Fortier, C., Groot, J. de, Hartfield, J. E.: "Plasma free corticosteroid response to faradic stimulation in the rat." *Acta Endocrinol. (Kbh.)* **30**: 219-221 (1959).

C63,267/59

Kellio, I. V. I., Tala, E. O. J.: "Changes in the free 17-hydroxycorticosteroid levels in plasma after electroshock therapy." *Acta Endocrinol. (Kbh.)* **30**: 99-108 (1959).

J11,258/59

Levine, S.: "Plasma-free corticosteroid response to electric shock in rats stimulated in infancy." *Science* **135**: 795-796 (1962).

D20,781/62

In rats manipulated during infancy, electric shocks caused significant increases of plasma corticoids within fifteen seconds, whereas nonmanipulated subjects did not show this response until after about five minutes. Furthermore, blood corticosteroid elevations were considerably higher in manipulated than in nonmanipulated animals.

Barchas, J. D., Freedman, D. X.: "Brain amines: response to physiological stress." *Biochem. Pharmacol.* **12**: 1232-1238 (1963).

E29,915/63

In rats, swimming to exhaustion especially in cold water caused depletion of brain 5-HT and NEP. Similar changes could not be obtained by having them run in a revolving cage, for under the conditions of the experiment the rats soon gave up and just allowed themselves to be dragged. On the other hand, immersion in cold water did reproduce the catecholamine depletion, whereas several other stressors (electroshock, starvation, hypoxia, surgery, adrenalectomy) were ineffective in this respect. The response is not dependent upon the pituitary-adrenocortical system, since active stressors deplete brain catecholamines even after hypophysectomy,

as does LSD. It is noteworthy that drugs that induce a similar change in brain amines produce a unique pattern of central excitation, acting on brain mechanisms concerned with metabolic and physiologic temperature regulation. "If the stressors have such a central action, a role for the biogenic amines in central as well as in peripheral aspects of temperature regulation should be sought."

Paulsen, E. C., Hess, S. M.: "The rate of synthesis of catecholamines following depletion in guinea pig brain and heart." *J. Neurochem.* **10**: 453-459 (1963).

D69,702/63

In guinea pigs, brain EP was restored about four hours after "electroshock stress." This relatively slow rate suggests that the animals sustained an aftereffect from the treatment. Data on the literature also indicate that electroshock decreases NEP in the brain of guinea pigs after prolonged swimming in cold water, whereas "insulin stress" allegedly causes no change in the catecholamine content of the brain.

Ferguson, H. C., Bartram, A. C. G., Fowlie, H. C., Cathro, D. M., Birchall, K., Mitchell, F. L.: "A preliminary investigation of steroid excretion in depressed patients before and after electro-convulsive therapy." *Acta Endocrinol. (Kbh.)* **47**: 58-68 (1964).

F19,672/64

In five women with depressive illness, electroshock therapy resulted in increased corticoid excretion with a diminution of 11-deoxy-17-oxosteroids. The changes were ascribed to stress.

Levi, R., Maynert, E. W.: "The subcellular localization of brain-stem norepinephrine and 5-hydroxytryptamine in stressed rats." *Biochem. Pharmacol.* **13**: 615-621 (1964).

G11,756/64

Electroshock decreased the total amount of brain stem NEP in normal but not in phenobarbital-sedated rats; it rose above normal in both shocked and unshocked rats treated with 1-phenyl-2-hydrazinopropane (Catron). The 5-HT concentration was altered only after treatment with Catron. Differential, gradient-density centrifugation of brain stem homogenates showed that NEP and 5-HT have approximately the same localization, about 25 percent being found in the fraction composed almost entirely of nerve ending particles. "It is suggested that in animals treated with sedatives or monoamine oxidase inhibitors the brain-stem NE,

ordinarily released by stress, fails to leave the nerve endings."

Wright, P. H., Malaisse, W. J.: "Effects of epinephrine, stress, and exercise on insulin secretion by the rat." *Am. J. Physiol.* **214**: 1031-1034 (1968). F97,956/68

In rats, various stressors (EP, swimming, electroshock) diminish insulin secretion. "It is suggested that endogenous epinephrine released during stress or exercise is sufficient to suppress insulin secretion even under conditions of hyperglycemia" (29 refs.).

Brown, G. M., Schalch, D. S., Reichlin, S.: "Patterns of growth hormone and cortisol responses to psychological stress in the squirrel monkey." *Endocrinology* **88**: 956-963 (1971). H37,353/71

In squirrel monkeys, various stressors (capture, chair restraint, intense sound and aversive conditioning) increase plasma STH and cortisol levels but the two responses do not run parallel and presumably are regulated by diverse mechanisms. In the case of chair restraint, STH values fall to resting levels whereas cortisol continues to rise.

Madden, J., Rollins, J., Anderson, D. C., Conner, R. L., Levine, S.: "Preshock-produced intensification of passive avoidance responding and of elevation in corticosteroid level." *Physiol. Behav.* **7**: 733-736 (1971). G90,607/71

In rats exposed to inescapable intense electroshock, corticosterone secretion was greater in preshocked animals (mild shock) than in nonpreshocked controls. Passive avoidance behavior was facilitated in preshocked rats.

Samorajski, T., Rolsten, C., Ordy, J. M.: "Changes in behavior, brain, and neuroendocrine chemistry with age and stress in C57-BL/10 male mice." *J. Gerontol.* **26**: 168-175 (1971). G83,474/71

Extensive studies on the histologic and biochemical changes induced by repeated electroshocks, with special reference to the acetylcholinesterase, 5-HT and NEP content of the brain and the histology of the brain, pituitary and adrenals.

Singh, A. K., Singh, R. K., Wahi, R. S., Tandon, A. K., Chansouria, J. P. N., Udupa, K. N.: "Endocrine and metabolic response to electric shock in rabbits: Part II. Changes in cortisone and insulin treated rabbits." *Indian J. Exp. Biol.* **10**: 412-414 (1972). J20,223/72

Allen, J. P., Denney, D., Kendall, J. W., Blachly, P. H.: "Corticotropin release during ECT in man." *Am. J. Psychiatry* **131**: 1225-1228 (1974). J18,141/74

Observations on psychiatric patients receiving electroshock treatment "suggest that the pituitary of man contains a readily dischargeable pool of ACTH that can be secreted promptly in response to a stressful stimulus. Furthermore, the pituitary has the capacity to respond to multiple successive seizures by maintaining elevated plasma ACTH concentrations as new but smaller boluses of ACTH are secreted following the first stimulus."

Pina-Cabral, J. M., Rodrigues, C.: "Blood catecholamine levels, factor VIII and fibrinolysis after therapeutic electroshock." *Br. J. Haematol.* **28**: 371-380 (1974). J18,676/74

Observations on patients undergoing therapeutic electroshock "suggest that while catecholamines are probably not responsible for plasminogen activator release during stress, adrenergic mediation of the concomitant increase in factor VIII is highly probable."

Swanson, D. W., Hanson, N. P., Rosenbaum, A. H., Swenson, W. M.: "Correlation of psychiatric factors and pituitary responsiveness: a negative report." *J. Nerv. Ment. Dis.* **158**: 100-103 (1974). J10,817/74

In both normal and schizophrenic patients, electroshock often caused a rapid increase in plasma FSH and LH, but this was inconstant and apparently not influenced by the mental disease.

Leenen, F. H., Shapiro, A. P.: "Effect of intermittent electric shock on plasma renin activity in rats." *Proc. Soc. Exp. Biol. Med.* **146**: 534-538 (1974). H87,670/74

In rats, repeated electroshocks caused a marked increase in both the renin and corticosterone concentration of plasma. Hypophysectomy did not inhibit the rise in plasma renin activity, which was blocked by dexamethasone and propranolol but potentiated by phentolamine. Presumably, "stress-induced release of renin is mediated via β -adrenergic receptors and... endogenous corticosteroids modify this response."

Bassett, J. R., Cairncross, K. D.: "Time course for plasma 11-hydroxycorticosteroid elevation in rats during stress." *Pharmacol. Biochem. Behav.* **3**: 139-142 (1975). J21,787/75

The time course of plasma 11-OHCS elevation "was studied in two stress situations: regular unsignalled foot shock which produces an intermediate steroid elevation and irregular signalled foot shock with the possibility of escape, which produces an extreme steroid elevation. The initial time course for steroid elevation followed a similar pattern for both treatment groups with the exception that in the irregular signalled group the plasma steroid elevation was more pronounced and there was an indication of biphasic response."

→Varia. O'Connor, W. J., Verney, E. B.: "The effect of increased activity of the sympathetic system in the inhibition of waterdiuresis by emotional stress." *Q. J. Exp. Physiol.* **33**: 77-90 (1945). 95,009/45

Altschule, M. D., Parkhurst, B. H., Tillotson, K. J.: "Decreases in blood eosinophilic leukocytes after electrically induced convulsions in man." *J. Clin. Endocrinol. Metab.* **9**: 440-445 (1949). B26,656/49

In psychiatric patients in whom approximately equal degrees of *eosinopenia* were produced by electroconvulsive therapy or ACTH, only the former caused clinical remission. Presumably, increased ACTH secretion is not the decisive factor responsible for improvement under these conditions.

Taylor, R. H., Gross, M., Ruby, I. J.: "Nonconvulsive electrostimulation and the pituitary-adrenocortical system." *J. Nerv. Ment. Dis.* **114**: 377-383 (1951).

J8,693/51

Both convulsive and nonconvulsive electrostimulation produced marked *eosinopenia* even in schizophrenic patients although earlier investigators claimed that these usually failed to show such a response. Pentothal anesthesia did not prevent this *eosinopenia* which was therefore not attributed to stress but to a direct action of electric current on the hypothalamus. The literature on the effect of electroshock upon blood eosinophils is reviewed (17 refs.).

Royce, J. R., Rosvold, H. E.: "Electroshock and the rat adrenal cortex." *Arch. Neurol. Psychiatry* **70**: 516-527 (1953).

B98,318/53

In rats, repeated electroshocks caused a considerable increase in the weight of the *adrenals*. A single shock sufficed to induce depletion of adrenal ascorbic acid and cholesterol whereas repeated shocks were followed

by a rise of these values above normal, suggesting functional hypertrophy (about 100 refs.).

Repeated intermittent electric shocks elevated the plasma *FFA* in rats. This was prevented by tranquilizers (pentobarbital and ethanol) in doses that by themselves cause no change in plasma *FFA*.

Reyna, L. J., DiMascio, A., Berezin, N.: "Psychological stress and experimental caries." *Psychosomatics* **8**: 138-140 (1967). F85,046/67

In rats, psychogenic stressors (electroshock, sound) can increase the incidence of *dental caries*.

Conner, R. L., Levine, S., Vernikos-Danellis, J.: "Shock-induced fighting and pituitary-adrenal activity." *Proc. 78th Convention, APA*. 1970, pp. 201-202.

J12,864/70

Observations on *fighting* behavior induced by electroshock in the rat.

Dropp, J. J., Sodetz, F. J.: "Autoradiographic study of *neurons* and *neuroglia* in autonomic ganglia of behaviorally stressed rats." *Brain Res.* **33**: 419-430 (1971).

J20,190/71

Knutson, J. F.: "The effects of shocking one member of a pair of rats." *Psychom. Sci.* **22**: 265-266 (1971). J11,343/71

When one member of a pair of rats was insulated from electric foot-shock, the frequency of *aggression* between them was greatly lowered. Also, the shocked rats developed relatively frequent, stereotyped, successful avoidance responses. Apparently, "avoidance or escape responses to shock will take priority over attack responses to shock."

Lauria, P., Sharma, V. N., Vanjani, S.: "Effect of prolonged stress of repeated electric shock on rat *myocardium*." *Indian J. Physiol. Pharmacol.* **16**: 315-318 (1972).

H80,120/72

Wald, E. D., Mackinnon, J. R., Desiderato, O.: "Production of gastric ulcers in the unrestrained rat." *Physiol. Behav.* **10**: 825-827 (1973). J3,751/73

In unrestrained rats, *gastrointestinal ulcers* developed following six hours of exposure to intermittent electroshocks.

+Varia. Covian, M. R.: "Role of emotional stress in the survival of adrenalectomized rats given replacement therapy." *J. Clin. Endocrinol.* **9**: 678 (1949).

B48,388/49

Unlike domesticated rats, wild Norway rats cannot be indefinitely maintained on sodium chloride after *adrenalectomy* and are particularly sensitive to the fatal effects of electroshock, "indicating that the emotional state of *captive wild rats* is such that therapy sufficient to offset the loss of adrenals in laboratory rats is insufficient to keep the wild rats alive."

Bliss, E. L., Migeon, C. J., Nelson, D. H., Samuels, L. T., Branch, C. H. H.: "Influence of E.C.T. and insulin coma on level of adrenocortical steroids in peripheral circulation." *Arch. Neurol. Psychiatry* **72**: 352-361 (1954). C1,997/54

In schizophrenics, electroconvulsive therapy as well as insulin coma increased the plasma level of 17-OHCS. When *diphenylhydantoin* was used to eliminate cyanosis, apnea and violent muscular movements, seizures still resulted in a rise in corticoids but of shortened duration.

Uhley, H. N., Friedman, M.: "Blood lipids, clotting and coronary atherosclerosis in rats exposed to a particular form of stress." *Am. J. Physiol.* **197**: 396-398 (1959). C73,763/59

In rats kept on a high-fat, high-cholesterol diet in a cage that periodically delivered electric shocks, unusually pronounced hypercholesterolemia, hyperlipemia and coronary atherosclerosis developed at the end of ten months.

Hall, C. E., Schneider, M., Hall, O.: "Increased sensitivity to x-irradiation exhibited by stressed rats." *Radiat. Res.* **17**: 118-126 (1962). D30,291/62

"Electroshock stress" applied before *x-irradiation* does not affect the survival rate of rats, but decreases it if applied afterwards. The same is true of the stress of being shipped to the laboratory.

Schapiro, S., Geller, E., Eiduson, S.: "Neonatal adrenal cortical response to stress and vasopressin." *Proc. Soc. Exp. Biol. Med.* **109**: 937-941 (1962). D24,932/62

In rats, electroshock (unlike natural or synthetic vasopressin) fails to elicit the usual ascorbic acid depletion and increase the corticosterone concentration of the adrenal cortex during the first eight days of life. This "stress-non-responsive period" (SNR period) is ascribed to the "immaturity of the hypothalamic osmoreceptor mechanism which underlies adjustments in vasopressin secretion."

Haltmeyer, G. C., Denenberg, V. H., Thatcher, J., Zarrow, M. X.: "Response of the neonatal rat after subjection to stress." *Nature* **212**: 1371-1373 (1966).

F74,906/66

In the rat, the stress of heat or electric shock during the first five days of life raises the adrenal and plasma concentration of corticosterone. Manifestly, the *neonatal* rat adrenal can respond normally to stressors by both an increased synthesis and release of corticoids. These data contradict earlier reports of a "stress-non-responsive period" (SNR) in this species. When adrenal ascorbic acid depletion is used as an indicator, the situation appears to be different, and reactivity also depends upon the stressor (20 refs.).

Rosenberg, A.: "Production of gastric lesions in rats by combined cold and electrostress." *Am. J. Dig. Dis.* **12**: 1140-1148 (1967). G51,611/67

In rats, combined exposure to *cold* and electrostress was much more effective in producing gastric lesions than either of these stressors alone. "The cold-electrostress-induced gastric lesions were prevented by atropine sulfate, atropine methyl nitrate and

propantheline." Several other central depressants were less effective or ineffective.

Doteuchi, M.: "Studies on the experimental gastrointestinal ulcers produced by reserpine and stress. I. Relationship between production of ulcers and changes in tissue monoamines." *Jap. J. Pharmacol.* **17**: 638-647 (1967). F96,238/67

Ader, R., Friedman, S. B., Grotta, L. J., Schaefer, A.: "Attenuation of the plasma corticosterone response to handling and electric shock stimulation in the infant rat." *Physiol. Behav.* **3**: 327-331 (1968).

H5,148/68

In eight-, fifteen- and twenty-one-day-old rats, stress-induced elevations of plasma corticosterone were first seen at fifteen days, at which time the response to handling and electric shock was similar. Twenty-one-day-old unmanipulated rats showed a greater reaction to electric shock than to handling. Previously shocked animals displayed little adaptation, whereas repeated handling diminished the plasma corticosterone response.

Treiman, D. M., Fulker, D. W., Levine, S.: "Interaction of genotype and environment as determinants of corticosteroid response to stress." *Dev. Psychobiol.* **3**: 131-140 (1970).

G82,877/70

In very young rats, "highly significant and opposing genetic and maternal effects inter-

acted to limit extreme plasma corticosterone concentrations following stress" (electroshock).

Creer, T. L.: "Hunger and thirst in shock-induced aggression." *Behav. Biol.* **8**: 433-437 (1973). H80,353/73

Hunger and thirst did not affect the mean of fighting among rats who initially showed considerable combativeness after electric shocks to the feet. Fasting likewise failed to alter the frequency of fighting in low-aggression rats but water deprivation increased it.

Vogel, J. R., Haubrich, D. R.: "Chronic administration of electroconvulsive shock effects on mouse-killing activity and brain monoamines in rats." *Physiol. Behav.* **11**: 725-728 (1973). J7,248/73

In rats, *mouse killing* tendencies are blocked by chronic electroconvulsive shocks as well as by antidepressant drugs. At the same time, brain NEP concentrations rise (23 refs.).

Thor, D. H., Ghiselli, W. B., Ward, T. B.: "Infantile handling and sex differences in shock-elicited aggressive responding of hooded rats." *Dev. Psychobiol.* **7**: 273-279 (1974). J12,750/74

Handling during infancy caused only minor changes in the aggressive response of male and female rats exposed to electric footshock in adulthood.

Magnetism

Several investigators reported data showing that mice, as well as squirrel monkeys and men, when placed in an electromagnetic field, develop manifestations of stress, particularly increased adrenocortical activity.

Magnetism

(See also our earlier stress monographs, p. xiii)

Barron, C. I., Dreher, J. J.: "Effects of electric fields and negative ion concentrations on test pilots." *Aerosp. Med.* **35**: 20-23 (1964). G37,107/64

The results of a study on pilots exposed to ionic or electric fields "neither support nor negate the hypothesis that negative ions or ions plus electric fields may be beneficial in ameliorating the effects of fatigue or stress."

Friedman, H., Becker, R. O., Bachman, C. H.: "Effect of magnetic fields on reaction time performance." *Nature* **213**: 949-950 (1967). E79,913/67

Observations on man "indicate that experimentally produced modulated magnetic fields can significantly affect reaction time performance." [The relationship of this finding to stress is not specifically discussed (H.S.).]

Barnothy, M. F., Sümegi, I.: "Abnormalities in organs of mice induced by a magnetic field." *Nature* **221**: 270-271 (1969).

H7,197/69

In a magnetic field, various organ changes occurred—especially in the adrenal cortex—that were suggestive of stress produced by other means.

J21,845/74

Microorganisms and Their Toxins

Infections are particularly powerful stressors, and the adaptive hormones produced during systemic stress can considerably influence resistance to microbes and their toxins.

In certain species such as the guinea pig, bacterial endotoxins frequently produce hemorrhagic necrosis of the adrenals, which can be prevented by hypophysectomy, but up to now it has not been possible to block it by destruction of hypothalamic nuclei except those situated near the stalk. This selective adrenal necrosis, often combined with the Waterhouse-Friderichsen syndrome, is so characteristic of certain bacterial toxins that it could hardly be a consequence of nonspecific stress alone. Probably, some special conditioning circumstances are involved in its pathogenesis, although these have not yet been clearly identified.

Polymorphonuclear leukocytosis is likewise so predominant during infection that its development must be facilitated by some specific conditioning circumstances; yet to a lesser degree, it also occurs (in combination with eosinopenia) following exposure to stressors other than microorganisms.

Numerous publications describe the typical stress-induced hormonal changes elicited by microorganisms and their toxins, particularly the rises in ACTH and glucocorticoid production. Certain bacterial polysaccharide preparations (for example, Piromen) are frequently used as standard stressors in clinical medicine, either to test the functional efficiency of the pituitary-adrenocortical system or as nonspecific therapeutic agents.

In man, bacterial pyrogens also augment plasma STH levels.

Among the factors which can particularly predispose to bacterial stressors are starvation, x-irradiation, artificial hibernation, and a rise in ambient temperature. On the other hand, a certain amount of crowding allegedly protects cockerels against *E. coli* infection, owing to cross-resistance. Furthermore, immune reactions to various antigens are strongly depressed by certain bacterial toxins. It remains to be shown whether this immunosuppressive effect is mediated exclusively by an increase in endogenous glucocorticoid production or by other factors as well.

Microorganisms and Their Toxins

(See also our earlier stress monographs, p. xiii)

Generalities. Schmid, R., Gonzalo, L., Blobel, R., Muschke, E., Tonutti, E.: "Über die hypothalamische Steuerung der ACTH-Abgabe der Hypophyse bei Diphtherie-Toxin-Vergiftung" (The hypothalamic regulation of ACTH secretion from the hypophysis in diphtheria toxin poisoning). *Endokrinologie* 34: 65-91 (1957).

D74,892/57

In guinea pigs, selective destruction of anterior or posterior hypothalamic nuclei could not prevent the hemorrhagic necrosis of the adrenals normally produced by bacterial endotoxin. Lesions situated closer to the pitu-

itary stalk did offer protection against this effect.

Schayer, R. W.: "Relationship of induced histidine decarboxylase activity and histamine synthesis to shock from stress and from endotoxin." *Am. J. Physiol.* 198: 1187-1192 (1960). C90,163/60

Dalmau-Ciria, M.: "Pirógenos y reacción de alarma" (Pyrogens and the alarm reaction). *Med. Clin. (Barcelona)* 40: 366-369 (1963). E31,173/63

Pyrogens are described as "alarmogens" in that they elicit the acute phase of the G.A.S.

Yuwiler, A., Geller, E., Schapiro, S., Guze, L. B.: "Absence of adrenocortical stress re-

sponses in experimental pyelonephritis." *Proc. Soc. Exp. Biol. Med.* **122**: 465-468 (1966). F67,285/66

In rats, pyelonephritis caused by intravenous *Streptococcus faecalis* produces no obvious evidence of general illness or any change in adrenocortical activity, characteristic of stress. Hence, "it seems most likely that experimental pyelonephritis simply does not elicit a stress response."

Gorizontov, P. D.: "Infection and corticosteroid hormones." *Klin. Med.* **44** No. 6: 5-12 (1966) (Russian). G43,190/66

Discussion of the relationships between infection and the G.A.S., with major emphasis, on the one hand, upon microbes and their toxins as stressors and, on the other, upon stress hormones as modifiers of infectious disease.

Berry, L. J., Agarwal, M. K., Snyder, I. S.: "Comparative effect of endotoxin and reticuloendothelial 'blocking' colloids on selected inducible liver enzymes." In: Luzio, N. R. di and Paoletti, R., *The Reticuloendothelial System and Atherosclerosis*, pp. 266-274. New York: Plenum Press, 1967. E7,069/67

In mice, stress induced by endotoxin lowers the activity of tryptophan pyrolase and increases that of tyrosine- α -ketoglutarate transaminase in the liver. Presumably, such enzyme responses are characteristic of stress.

Rosoff, C. B., Goldman, H.: "Effect of the intestinal bacterial flora on acute gastric stress ulceration." *Gastroenterology* **55**: 212-222 (1968). G60,200/68

In rats, polymyxin B offers significant protection against acute stress ulcers elicited by restraint, probably because this nonabsorbable antibiotic reduces the coliform bacteria in the intestine. "This change in the flora results in a decrease in the motor tone of the stomach and cecum, and in the volume and concentration of gastric acid produced in response to the stress of immobilization. The protection offered by the coliform-poor state is eliminated when endotoxin is given to antibiotic-treated animals." Conversely, systemic administration of endotoxin increases both gastric acid and stress ulcers. "It is suggested that, under the conditions induced by stress, detoxification mechanisms suffer and permit absorbed bacterial products to reach the systemic circulation and stimulate the hypothalamus."

Richardson, R. S., Norton, L. W., Sales,

J. E. L., Eiseman, B.: "Gastric blood flow in endotoxin-induced stress ulcer." *Arch. Surg.* **106**: 191-195 (1973). G99,516/73

In pigs, endotoxin shock invariably caused stress ulcers of the stomach, with changes in the gastric circulation.

Huldt, G., Gard, S., Olovson, S. G.: "Effect of toxoplasma gondii on the thymus." *Nature* **244**: 301-303 (1973).

H78,384/73

In adult mice infected with *Toxoplasma gondii*, thymus weight and immune responses were severely depressed. "A direct thymocytolytic effect of the toxoplasms can probably be ruled out, as they were never found in thymic lymphocytes and experiments on cultured lymphocytes have failed to indicate any direct or indirect lytic effect of the parasite. The possibility of some kind of interference with the differentiation and migration of thymocytes should be considered."

Terragna, A., Rossolini, A., Bianchini, A. M., Cellesi, C., Mattei, C.: "Alterazioni metaboliche nello shock da batteri Gram negativi. Ricerche sperimentali" (Metabolic changes in shock produced by Gram negative bacteria. Experimental studies). *G. Mal. Infett.* **25**: 529-557 (1973). J11,411/73

Small monograph on the metabolic, histochemical and EM alterations characteristic of endotoxin shock in the rabbit (almost 100 refs.).

Goodenough, S., Simmons, G., Mullane, J., Feldman, N., Huber, G.: "Impairment of pulmonary antibacterial defenses by experimental stress" (abstracted). *Clin. Res.* **22**: 442A (1974).

H90,289/74

In rats, the stress of restraint reduced resistance to infection, especially in the lungs. "Alveolar lining material from stressed animals had diminished alveolar macrophage bactericidal stimulating activity, implying that the effect of the stress-induced impairment is mediated through this acellular alveolar lining component of the host defense system rather than on the cellular alveolar macrophage component."

Greenberg, L., Himal, H. S.: "Hydrochloric acid clearance and endotoxin induced duodenal erosions in dogs." *Surg. Gynecol. Obstet.* **139**: 561-565 (1974).

H92,596/74

In dogs, intravenous endotoxin inhibited transmucosal hydrogen ion passage, bile flow and pancreatic juice flow, all of which normally cleared instilled hydrochloric acid.

When the bile and pancreatic ducts were ligated and acid given, the high concentration of hydrochloric acid remaining in the pouches led to acute duodenal erosions. When no acid was instilled, endotoxin markedly stimulated fluid and electrolyte flow into the lumen, and this was associated with hemorrhagic necrosis of the duodenal mucosa. The authors conclude that duodenal damage caused by endotoxin may vary from acute focal erosions to hemorrhagic necrosis, depending upon the ability of the duodenum to clear hydrochloric acid.

Leise, E. M., LeSane, F., Gray, I.: "Lymphocyte and polymorphonuclear enzymes in stress. IV. Changes associated with an acute bacterial infection with *Diplococcus pneumoniae*." *Biochem. Med.* 9: 206-213 (1974). J11,685/74

Leise, E. M., LeSane, F., Gray, I.: "V. Changes associated with a viral infection: herpes simplex." *Biochem. Med.* 9: 214-224 (1974). J11,686/74

Holtzman, S., Schuler, J. J., Earnest, W., Erve, P. R., Schumer, W.: "Carbohydrate metabolism in endotoxemia." *Circ. Shock.* 1: 99-105 (1974). J14,353/74

In rats, dexamethasone, even after endotoxin, reduced the magnitude of changes in carbohydrate metabolism. Presumably, one of the beneficial effects of glucocorticoids "may be to confer protection in endotoxemia by stimulating gluconeogenesis" (27 refs.).

Bertók, L., Kocsár, L. T.: "Die Rolle des Endotoxins beim intestinalen Syndrom der Strahlenkrankheit" (The role of endotoxin in the intestinal syndrome of radiation disease). *Wiss. Z. Karl-Marx Univ. Leipzig, Math.-Naturwiss. R.* 23: 65-66 (1974). J15,372/74

In rats sensitized with lead acetate, minute doses of bacterial endotoxin sufficed to cause death. By the use of this technique it could be demonstrated that following x-irradiation, endotoxin is absorbed into the blood. Hence, endotoxinemia probably plays an important role in the irradiation syndrome.

Bailenger, J., Carcenac, F.: "Répercussions du parasitisme par *Strongyloides ratti* sur la sécrétion des gluco-cortico-stéroïdes chez le rat." (Repercussions of parasitism by *Strongyloides ratti* on the secretion of glucocorticoids in the rat). *Int. J. Parasitol.* 4: 307-310 (1974). J16,045/74

In rats, infestation with *Strongyloides ratti* leads to increased glucocorticoid secretion during the alarm reaction, with a hypofunc-

tion of the adrenals allegedly related to the phase of resistance of the G.A.S.

→**Hormones.** Altschule, M. D., Parkhurst, B. H., Promisel, E.: "Effects of intravenous injection of typhoid vaccine on blood leukocytes and adrenal cortex." *Arch. Intern. Med.* 86: 505-518 (1950). B26,082/50

In patients given typhoid vaccine intravenously for the treatment of psychoses, there was lymphopenia, eosinopenia and fever. The ratio of urinary uric acid to creatinine varied inversely with the fever. 17-KS excretion followed a pattern typical with other stressors.

Bliss, E. L., Migeon, C. J., Branch, C. H., Samuels, L. T.: "Reaction of the adrenal cortex to emotional stress." *Psychosom. Med.* 18: 56-76 (1956). C13,032/56

In normal people and in psychiatric patients emotional stress (subjectively estimated by manifestations of anxiety and tension), whether occurring spontaneously or elicited experimentally, caused consistent but very modest increases in blood and urinary 17-OHCS. These changes were always much less pronounced than those produced by ACTH, Piromen, insulin, electroshock or moderate physical exercise.

Wexler, B. C., Faehnrich, J. L., Weiss, M. E., Grace, O. D.: "The use of bacterial polysaccharide (Piromen) as a pituitary-adrenal stimulant in dogs." *Am. J. Vet. Res.* 18: 642-647 (1957) (26 refs.).

C51,233/57

Wexler, B. C., Dolgin, A. E., Zaroslinski, J. F., Tryczynski, E. W.: "Effects of a bacterial polysaccharide (Piromen) on the pituitary adrenal axis: cortisone blockade of Piromen-induced release of ACTH." *Endocrinology* 63: 201-204 (1958).

C56,640/58

In rats, ACTH release by bacterial polysaccharide (Piromen) is blocked by cortisone but not by DOC.

Frommel, E., Fleury, C., Ledebur, I. von, Beguin, M.: "On the differential mobilisation of adrenalin and cortisone in the progress of stress under hypothermic conditions of external cause and of vaccine fever." *Med. Exp. (Basel)* 6: 261-264 (1962). D27,769/62

In guinea pigs, hypothermia "due to refrigeration, mobilizes adrenalin with an ephemeral action and brief duration, whereas vaccine fever stimulates the hormones of the adrenal cortex, possessing a slower and more lasting effect."

Fukui, S.: "The influence of stress upon the excretion of adrenocortical hormone in pulmonary tuberculosis. II." *Kekkaku* **37**: 125-129 (1962) (Japanese). J23,475/62

Greenwood, F. C., Landon, J.: "Growth hormone secretion in response to stress in man." *Nature* **210**: 540-541 (1966).

F65,986/66

In man, anxiety causing emotional stress or injection of pyrogen (kind not specified) increased plasma STH levels.

Frohman, L. A., Horton, E. S., Lebovitz, H. E.: "Growth hormone releasing action of a pseudomonas endotoxin (Piromen)." *Metabolism* **16**: 57-67 (1967). F75,314/67

In man, *Pseudomonas* endotoxin given intravenously elevates both the ACTH and the STH levels of the plasma.

Jenkins, J. S.: "The pituitary-adrenal response to pyrogen." In: James, V. H. T. and Landon, J., *Memoirs of the Society for Endocrinology*. No. 17, pp. 205-212. Cambridge: Cambridge University Press, 1968.

E7,508/68

In man, the stressor effect of bacterial pyrogens provides a useful test of pituitary-adrenal reactivity as indicated by the resulting increase in plasma cortisol. "If our present views on the pituitary site of its action are correct, the pyrogen test would seem to be complementary to such procedures as the vasopressin test, where the site of action seems to lie in the hypothalamus."

Matsui, N., Ishihara, I., Ukai, M., Miyakawa, M.: "Germfree environment and adrenocortical function in the rat." *A.R. Res. Inst. Env. Med. Nagoya Univ.* **19**: 51-60 (1972).

H80,428/72

Circadian variations in plasma and adrenal 11-OHCS were somewhat smaller in adult germfree rats than in conventional rats, although the plasma 11-OHCS levels were slightly higher. The stress of handling caused the usual increase in both plasma and adrenal 11-OHCS.

Zeitoun, M. M., Hassan, A. I., Hussein, Z. M., Fahmy, M. S., Ragab, M., Hussein, M.: "Adrenal glucocorticoid function in acute viral infections in children." *Acta Paediatr. Scand.* **62**: 608-614 (1973).

J9,160/73

In Egyptian children, plasma 17-OHCS levels rose under the influence of all viral infections studied (measles, chickenpox, mumps, poliomyelitis). ACTH and metyra-

pone tests revealed normal pituitary-adrenal function (25 refs.).

Spackman, D., Riley, V.: "Increased corticosterone, a factor in LDH-virus induced alterations of immunological responses in mice" (abstracted). *Proc. Am. Assoc. Cancer Res.* **15**: 143 (1974). H83,767/74

In mice, LDH-virus increases blood corticosterone levels and causes thymus involution with lymphocytopenia, that is, it causes a stress reaction. It is possible that LDH-virus modifies neoplastic diseases by inhibiting immune responses through its stressor effects.

Rayfield, E. J., George, D. T., Beisel, W. R.: "Altered growth hormone homeostasis during acute bacterial sepsis in the rhesus monkey." *J. Clin. Endocrinol. Metab.* **38**: 746-754 (1974). H86,214/74

Studies on monkeys suggest that chlorpromazine can suppress the exaggerated STH response following an intravenous glucose load during the stress of acute infection.

+Varia. Malmros, H.: "The relation of nutrition to health. A statistical study of the effect of the war-time on arteriosclerosis, cardiosclerosis, tuberculosis and diabetes." *Acta Med. Scand.* **138**: 137-153 (1950).

B60,638/50

During the postwar years in Germany *starvation* increased the incidence of tuberculosis.

Egdahl, R. H.: "The differential response of the adrenal cortex and medulla to bacterial endotoxin." *J. Clin. Invest.* **38**: 1120-1125 (1959).

G33,275/59

In dogs, *spinal cord transection* at C-7 abolishes adrenal medullary discharge by large doses of bacterial endotoxin but leaves febrile, hypotensive and adrenal cortical responses intact. "Epinephrine release is not necessary for the febrile and adrenocortical stimulating effects of endotoxin."

Vaškú, J.: "Die Beeinflussung der experimentellen diphtherischen Intoxikation durch den künstlichen Winterschlaf" (The influence of artificial hibernation on experimental diphtheria intoxication). *Z. Gesamte Inn. Med.* **16**: 885-894 (1961). D80,395/61

Hibernation did not protect guinea pigs against the adrenal changes elicited by diphtheria toxins, but it did increase their sensitivity as indicated by a rise in mortality. The "artificial hibernation" (drugs plus cold) used in these experiments acted as a stressor.

Noble, G. A.: "Stress and parasitism. I. A preliminary investigation of the effects of stress on ground squirrels and their parasites." *Exp. Parasitol.* **11**: 63-67 (1961).

G38,126/61

In ground squirrels (*Citellus armatus*), exposure to various stressors increased susceptibility to infection with protozoa, mostly Trichomonas.

Siegel, H. S., Gross, W. B.: "Social grouping, stress and resistance to coliform infection in cockerels." *Poult. Sci.* **44**: 1530-1536 (1965).

G37,829/65

In cockerels subjected to various types of social grouping, "evidences of mild stress such as lower total leucocytes, increased adrenal weight, reduced bursa weight and/or reduced adrenal cholesterol concentrations were discernible." *E. coli* infection caused more severe leukopenia and plasma corticosterone levels rose, but under certain conditions there was "cross" or 'nonspecific' resistance as suggested by Selye."

Gross, W. B., Siegel, H. S.: "The effect of social stress on resistance to infection with *Escherichia coli* or *Mycoplasma gallisepticum*." *Poult. Sci.* **44**: 998-1001 (1965).

J11,921/65

"Social stress" was produced in chickens by moving males into cages with other birds according to a schedule that kept contact with previously encountered birds to a minimum. After two weeks their resistance to *E. coli* inoculation was increased but their sensitivity to *Mycoplasma gallisepticum* remained unchanged.

Osborne, J. C., Meredith, J. H.: "The influence of environmental and surgical stressors on susceptibility to bacterial endotoxin." *Exp. Med. Surg.* **28**: 39-44 (1970).

H39,299/70

In young piglets, "stress associated with transport, weaning, sunburn and a new environment appeared to be responsible for a state of decreased susceptibility to bacterial endotoxin."

Hamilton, P. B., Harris, J. R.: "Interaction of aflatoxicosis with *Candida albicans* infections and other stresses in chickens." *Poultry Sci.* **50**: 906-912 (1971).

J21,253/71

Kurasz, S., Musiatowicz, B., Borzuchowska, A., Swiderska, K.: "Histologische und histochemische Veränderungen in der Nebennierenrinde des Kaninchens nach experimenteller Infektion mit *Salmonella typhi murium* und Bestrahlung" (Histologic and histochem-

ical changes of the adrenal cortex of rabbits after experimental infection with *Salmonella typhimurium* and irradiation). *Zentralbl. Bakteriol. [Orig. A]* **224**: 463-471 (1973).

J11,180/73

In rabbits, infection with *Salmonella typhimurium* plus *x-irradiation* produces adrenocortical changes characteristic of the alarm reaction. These are more intense following exposure to both agents than after application of either of them alone.

Wessenberg, H.: "The pathogenicity of entamoeba histolytica: is heat stress a factor?" *Perspect. Biol. Med.* **17**: 250-266 (1974).

H81,930/74

Review of the literature and personal observations suggest that heat stress, especially in combination with physical exertion and solar radiation, predisposes to infection with *Entamoeba invadens* and *histolytica*. In military epidemics, the emotional factor of anxiety also plays an important role. "Whether or not heat stress is the directly antecedent cause of tissue invasion, the lesson seems clear regarding the danger of heat stress to carriers of the amoebae or to those exposed to infection" (66 refs.).

Melby, J. C.: "Systemic corticosteroid therapy: pharmacology and endocrinologic considerations." *Ann. Intern. Med.* **81**: 505-512 (1974).

J16,876/74

In patients with rheumatoid arthritis, pyrogen therapy was often superior to treatment with glucocorticoids. "High-dose corticosteroid therapy abolished the hypothalamic-pituitary-adrenal response to pyrogen stress, whereas low doses of steroids produced only insignificant alterations to the response to pyrogen stress. Other studies involving testing of the negative feedback response (metyrapone test) may be abnormal even at rather modest doses of corticosteroids."

Gross, W. B.: "Stressor effects of initial bacterial exposure of chickens as determined by subsequent challenge exposures." *Am. J. Vet. Res.* **35**: 1225-1228 (1974).

J23,893/74

Chickens bred for a low concentration of plasma corticosterone "inoculated initially with live or killed *Escherichia coli* had increased resistance to *E. coli*, lessened resistance to *Mycoplasma gallisepticum*, and reduced capability to produce antibody." Chickens selected for a high corticosterone concentration were less responsive to the initial inoculation. Metyrapone blocked the resistance induced by the exposure to *E. coli*.

Immunity

As expected, any intense immune reaction, particularly serum sickness or severe allergy, can act as a powerful stressor. In guinea pigs sensitized with heterologous protein, repeated injections of the antigen have been said to produce the typical three stages of the G.A.S.

In rabbits, repeated inoculation with foreign proteins causing a protracted state of hypersensitivity can bring on cardiovascular and renal lesions similar to those elicited by other stressors.

Immunity

(See also our earlier stress monographs, p. xiii)

Cutuly, E., Cutuly, E. C.: "Inhibition of gonadotropic activity by sex hormones in parabiotic rats." *Endocrinology* **22**: 568-578 (1938). 72,076/38

Rats united by parabiosis go through a critical period during the first or second week after the operation. "In this stage the animals may present one or all of the symptoms described by Selye under the term 'alarm reaction.'"

Dougherty, T. F., White, A.: "Pituitary-adrenal cortical control of lymphocyte structure and function as revealed by experimental X-radiation." *Endocrinology* **39**: 370-385 (1946). 95,612/46

"CBA mice, 60 to 80 days old, received total body X-radiation. A large dose of X-rays, 200 r, produced within 3 hours a lymphopenia, tissue lymphocyte degeneration, and total serum protein and gamma globulin increases. These changes also occurred in 1 day postoperative adrenalectomized mice receiving 200 r. This dose gave an anamnestic response in previously immunized mice in the absence of the adrenals." Smaller x-ray doses were effective in intact but not in adrenalectomized mice, presumably because the action is partially mediated through the pituitary-adrenal axis.

Thompson, R. M., Arnold, A. C., Mitchell, R. B.: "Effects of stresses associated with flying on the cardiovascular-renal lesions produced by hypersensitive reactions. I. Effects of acute altitude exposure on the cardiovascular-renal lesions in hypersensitive animals." *Tex. Rep. Biol. Med.* **9**: 834-853 (1951). B75,765/51

Hypersensitivity to foreign proteins and/or hypoxia was induced in rabbits. "The degree of heart and kidney damage was much

greater with a combination of the protracted hypersensitive state and exposure to simulated high altitude than in the animals prepared with either the hypersensitive state alone or the altitude stress alone."

Gupta, S., Kumar, S.: "Studies in anaemia of infection. Part VI. Relation of plasma iron with stress and adreno-cortical function." *Indian. J. Med. Res.* **48**: 140-145 (1960). C99,744/60

Since various divergent stimuli, including infections, produce a common state of distress in rabbits and man, "it is postulated that 'stress' caused by these stimuli may be concerned in some way with the production of hypoferraemia."

Marsh, J. T., Lavender, J. F., Chang, S. S., Rasmussen, A. F.: "Poliomyelitis in monkeys: decreased susceptibility after avoidance stress." *Science* **140**: 1414-1415 (1963). D69,198/63

In cynomolgus monkeys, "avoidance stress" prior to inoculation with Type I polio-virus protected against the fatal effect of the infection. The circulating lymphocytes decreased significantly during stress. These findings contrasted sharply with earlier observations in which stressors diminished the resistance of mice to virus infection. However, a factor of different timing may be important (10 refs.).

Johnsson, T., Lavender, J. F., Hultin, E., Rasmussen, A. F. Jr.: "The influence of avoidance-learning stress on resistance to Coxsackie B virus in mice." *J. Immunol.* **91**: 569-575 (1963). G37,497/63

Mice became particularly susceptible to infection with Coxsackie virus B1 during avoidance learning stress. Furthermore, "a significantly higher virus titer could be demonstrated in the pancreas, liver, heart and muscle of stressed mice as compared to unstressed mice."

Fortak, W.: "Morphologic and histochemical investigations of the adrenal gland in guinea pigs during sensitization with heterologous protein." *Endokrinol. Pol.* **16**: 457-473 (1965) (Polish). F72,853/65

In guinea pigs sensitized with heterologous protein, the adrenals "show typical, three-phasic changes, indicating hypersecretion of the hormones during the early period of sensitization, and relative stability of hormone secretion during the unstable period of sensitization but hormonal exhaustion during the late period of sensitization. In the late period of sensitization the guinea pigs showed the highest sensitivity after the second application of protein antigen. From the results obtained the author concludes that the pathogenesis of the changes in the adrenal glands can be explained on the basis of Selye's General Adaptation Syndrome."

Johnsson, T., Rasmussen, A. F.: "Emotional stress and susceptibility to poliomyelitis virus infection in mice." *Arch. Gesamte Virusforsch.* **17**: 392-397 (1965).

G36,032/65

In mice, the stress induced by avoidance learning increased susceptibility to poliomyelitis virus.

inoculated with Coxsackie B viruses." *Psychosom. Med.* **27**: 361-368 (1965).

J15,626/65

In mice exposed to various environmental stressors, susceptibility to infection with Coxsackie virus B2 was greatly increased.

Anderlik, P., Bános, Z., Szeri, I., Koltay, M., Virág, I.: "Response to stressors of mice undergoing graft-versus-host reaction." *Experientia* **26**: 94-95 (1970).

H21,168/70

In mice, intravenous injection of homologous splenic cells causes lymphopenia with body weight loss. Following such treatment, these animals no longer respond to a second stressor with further lymphopenia.

Huldt, G., Gard, S., Olovson, S. G.: "Effect of toxoplasma gondii on the thymus." *Nature* **244**: 301-303 (1973).

H78,384/73

In adult mice infected with *Toxoplasma gondii*, thymus weight and immune responses were severely depressed. "A direct thymocytolytic effect of the toxoplasms can probably be ruled out, as they were never found in thymic lymphocytes and experiments on cultured lymphocytes have failed to indicate any direct or indirect lytic effect of the parasite. The possibility of some kind of interference with the differentiation and migration of thymocytes should be considered."

Hypoxia, Decreased Barometric Pressure and Hyperbaric Oxygenation

The stressor effects of hypoxia and decreased barometric pressure have been examined mainly in connection with aerospace medicine, diving, mountaineering and populations normally living at very high altitudes. As expected, lack of oxygen can produce typical stress manifestations such as a discharge of ACTH, glucocorticoids and catecholamines, eosinopenia, lymphopenia and decreased performance in various classic stress tests. At the same time, there is adrenal enlargement with loss of cholesterol and lipids, and thymus atrophy with a variety of nonspecific metabolic changes.

As with so many other stressors encountered in daily life, hypoxia rarely affects man unaccompanied by conditioning factors whose effects are difficult, if not impossible, to separate from those of a lack of oxygen in itself. Among these, the most important are an increase in carbon dioxide or—in the case of mountaineering, diving or parachute jumping—emotional excitement, cold and muscular fatigue.

Upon prolonged exposure to high altitudes or other agents associated with comparative oxygen deficiency, a considerable degree of adaptation can occur.

In rats under reduced oxygen tension, the body temperature drops but returns to normal after three or four days. This acquired adaptation is not dependent on the

presence of the adrenals since it persists after adrenalectomy if the animals are maintained on corticoids.

Interestingly, rats subjected to oxygen under pressure develop an adrenal enlargement with lipid depletion not unlike that caused by hypoxia. Here again, an elevation of tissue carbon dioxide may be a complicating factor.

Adrenalectomy allegedly increases survival after exposure to high oxygen pressure; this protection is said to be counteracted both by adrenocortical extract and EP.

Up to now, only a few investigators have reported any changes in blood insulin, glucagon, renin, or urinary aldosterone levels as a result of exposure to high altitudes.

In fasted rats exposed to reduced oxygen pressure, hepatic glycogen stores accumulate considerably, but this may be due to a loss of carbon dioxide caused by hyper-ventilation rather than to hypoxia per se.

Increased lactic acid excretion (similar to that produced by EP) has been regarded as an indicator of the severity of hypoxic stress.

Stimulation of splenic erythropoiesis is undoubtedly a specific adaptive response to lack of oxygen. It remains to be seen, however, whether the malformations occasionally observed in the young of mice exposed to hypoxia in pregnancy are true stress manifestations although malformations have been noted in the offspring of animals and women exposed to other stressors during pregnancy.

Among the factors that can significantly affect the stress response to hypoxia, temperature variations, muscular work and malnutrition have received special attention.

Hypoxia, Decreased Barometric Pressure including Hyperbaric Oxygenation

metabolic and hormonal consequences. Probably, one important factor is hypoxia.

Morrison, P.: "Responses of mountaineers to multiple stressors. A program in human ecology." *Arch. Environ. Health* **17**: 599-602 (1968). G61,522/68

Mountaineers ascending Mount MacKinley (20,320 ft.) and exposed to the multiple stressors of altitude, cold, nutritional deficiency, dehydration, wind, confinement and isolation were tested for urinary and plasma cortisol, plasma catecholamines, proteins, lactic dehydrogenase, creatine phosphokinase, as well as EEG and neurophysiologic activity. The results of these tests are not described in detail although they were repeated later under laboratory conditions in an altitude chamber. It was clear, however, that extreme lassitude and somnolence affected those who reached the summit and memory was badly impaired as indicated by their capacity to repeat random numbers forward and backward. The digit recall ability was reduced even after return to sea level.

Hunter, C., Clegg, E. J.: "Changes in body weight of the growing and adult mouse in response to hypoxic stress." *J. Anat. (Lond.)* **114**: 185-199 (1973). J2,541/73

→**Morphology.** Thorn, G. W., Jones, B. F., Lewis, R. A., Mitchell, E. R., Koepf, G. F.: "The role of the adrenal cortex in anoxia: the effect of repeated daily exposures to reduced oxygen pressure." *Am. J. Physiol.* **137**: 606-619 (1942). A57,759/42

In rats, rabbits and dogs exposed to decreased barometric pressure, the adrenals enlarge and show signs of hyperactivity. Adrenalectomy greatly reduces resistance to hypoxia.

Dalton, A. J., Mitchell, E. R., Jones, B. F., Peters, V. B.: "Changes in the adrenal glands of rats following exposure to lowered oxygen tension." *J. Natl. Cancer Inst.* **4**: 527-536 (1944). 84,981/44

In rats exposed to decreased oxygen tension there was an immediate loss of adrenocortical lipids which could be prevented by

adrenocortical extract. After the rats' repeated exposure to hypoxia, the adrenal enlargement was associated with an increase of its lipid granules, often above the initial level.

Hailman, H. F.: "The effect of preventing acapnia on adrenal cortical hypertrophy under conditions of decreased barometric pressure." *Endocrinology* **34**: 187-190 (1944).

A69,734/44

In rats, an excess of CO₂ inhibits the adrenal hypertrophy caused by lack of oxygen at a given low barometric pressure. "It is suggested that the adrenal cortex is stimulated by either a relative or absolute increase in basic cations or acidic anions. In the former case the adrenal cortex secretes a hormone increasing the excretion of sodium in the urine and in the latter case a hormone preventing the excretion of sodium in the urine."

Nichols, J.: "Quantitative histochemical changes in the adrenal following exposure to anoxia." *J. Aviat. Med.* **19**: 171-178 (1948).

B26,390/48

In rats, anoxia depletes the adrenal cholesterol esters before the free cholesterol, and the other lipid fractions disappear even more slowly. Conversely, cholesterol esters recover last upon interruption of anoxia. The changes are ascribed to the G.A.S. (29 refs.).

Bean, J. W., Johnson, P. C.: "Adrenocortical response to single and repeated exposure to oxygen at high pressure." *Am. J. Physiol.* **179**: 410-414 (1954). C1,583/54

In rats exposed to oxygen under pressure, adrenal enlargement with lipid depletion occurs either because of a direct stressor effect exerted by the stimulus or through an elevation of tissue CO₂ and the enzyme poisoning caused by it.

Krasnovskaia, I. A.: "Changes in hypothalamo-hypophyseal neurosecretory system of rats under conditions of prolonged hypoxia." *Probl. Endokr.* **20** No. 2: 53-57 (1974) (Russian). H92,515/74

In rats exposed to hypoxia, histologic evidence of decreased neurosecretion was noted in the paraventricular nucleus of the hypothalamus, presumably as a consequence of "training".

→Hormones. Pincus, G., Hoagland, H: "Steroid excretion and the stress of flying." *J. Aviat. Med.* **14**: 173-193 (1943).

84,492/43

In subjects found fatigued on the Steven's serial coordination meter or the Hoagland-Werthessen pursuit meter, and in pilots on test flights or instruction flights, there was increased urinary 17-KS excretion that caused diuresis. Poor response on the Hoagland-Werthessen pursuit meter was associated with poorer performance with increasing "altitude" owing to reduced oxygen tension. Presumably, "the simulated and actual stress of flying studied induces adrenal steroid hormone hypersecretion that is reflected in the 17-ketosteroid output; this hypersecretion either causes or is accompanied by diuresis."

Burrill, M. W., Ivy, A. C.: "Excretion of neutral 17-ketosteroids in human subjects repeatedly exposed to hypoxia under conditions of simulated high altitude." *J. Appl. Physiol.* **2**: 437-445 (1950). B48,847/50

In man, intermittent exposure to simulated altitudes of 18,000 ft. causes an initial decrease followed by an increase in 17-KS excretion but as exposure continues this change gradually disappears. Hyperventilation tends to enhance KS elimination. "The results show that some alteration in ketosteroid excretion occurs in the response of the human subject to conditions of simulated altitude. These results alone, however, cannot be considered proof that the adrenal cortex is functionally involved in this response."

Koller, F., Schwarz, E., Marti, M.: "Ueber die Reaktion der Nebennierenrinde beim Aufstieg ins Hochgebirge" (The reaction of the adrenal cortex during passive ascent to high altitudes). *Acta Endocrinol. (Kbh.)* **16**: 118-140 (1954). B96,680/54

In normal people, a sudden ascent of 2,650 m. by rail from Lauterbrunnen to Jungfraujoch causes an increase in thrombocytes and total leukocyte count, a decrease in eosinophils and antithrombin, and an increase in excretion of 17-KS and of reducing-corticoids. It is concluded that passive ascent to high altitudes produces a typical "unspecific stress reaction, the origin of which, however, is not yet clearly understood." Hypoxia alone

cannot be responsible for it since exposure to a comparable drop in oxygen tension within a low pressure chamber is not equally effective.

Timiras, P. S., Pace, N., Hwang, C. A.: "Plasma and urine 17-ketosteroid levels in man during acclimatization to high altitude." *Fed. Proc.* **16**: 340 (1957). C33,237/57

Barchas, J. D., Freedman, D. X.: "Brain amines: response to physiological stress." *Biochem. Pharmacol.* **12**: 1232-1238 (1963). E29,915/63

In rats, swimming to exhaustion especially in cold water caused depletion of brain 5-HT and NEP. Similar changes could not be obtained by having them run in a revolving cage, for under the conditions of the experiment the rats soon gave up and just allowed themselves to be dragged. On the other hand, immersion in cold water did reproduce the catecholamine depletion, whereas several other stressors (electroshock, starvation, hypoxia, surgery, adrenalectomy) were ineffective in this respect. The response is not dependent upon the pituitary-adrenocortical system since active stressors deplete brain catecholamines even after hypophysectomy, as does LSD. It is noteworthy that drugs that induce a similar change in brain amines produce a unique pattern of central excitation acting on brain mechanisms concerned with metabolic and physiologic temperature regulation. "If the stressors have such a central action, a role for the biogenic amines in central as well as in peripheral aspects of temperature regulation should be sought."

Mazeaud, M.: "Influence de divers facteurs sur l'adrénalinémie et la noradrénalinémie de la carpe" (The influence of different factors on blood adrenaline and noradrenaline in the carp). *C. R. Soc. Biol.* (Paris) **158**: 2018-2021 (1964). F36,962/64

In the carp, muscular activity and hypoxia cause a slight increase in the EP and a marked rise in the NEP content of the blood. The latter values also rise considerably after hemorrhage and trauma.

Doležal, V., Luxa, J., Svačinka, J., Rybák, R., Zemanova, Z., Samek, L., Čermak, K.: "The influence of 6 days sojourn in mountains on human efficiency." *Riv. Med. Aero-naut. Spaz.* **29**: 383-401 (1966). F75,919/66

In eight young men who spent six days at a 1,500 m. altitude in the High Tatra mountains, a gradual disappearance of signs con-

sidered to be characteristic of stress suggested a particularly rapid development of adaptation. Although there were changes in corticoid and catecholamine excretion, these were variable and unaccompanied by esinopenia. Besides, it would have been impossible to distinguish clearly between the results of hypoxia, physical stress and emotional excitement.

Ulvedal, F., Roberts, J. J.: "Study of man during a 56-day exposure to an oxygen-helium atmosphere at 258 mm. Hg total pressure. VI. Excretion of steroids and catecholamines." *Aerosp. Med.* **37**: 572-578 (1966). F93,442/66

Men kept in a double-walled space cabin simulator in an oxygen-helium atmosphere showed no significant disturbance in glucocorticoid or catecholamine elimination. A reversal of the corticoid excretion rhythm was noted in subjects who slept during the day and worked at night (22 refs.).

Mefferd, R. B. Jr., Wieland, B. A.: "Comparison of responses to anticipated stress and stress." *Psychosom. Med.* **28**: 795-807 (1966). G42,966/66

Young airmen were exposed to actual or anticipated severe hypoxia. Catecholamine and corticoid secretion as well as other metabolic changes were used as objective indicators of stress. There were great individual variations in the response to anticipated stress: "some reacted hardly at all, while others had an alarm reaction. Upon actual exposure to hypoxia (except for those compensatory adaptations specific to hypoxia) these general responses simply increased in magnitude in all subjects, i.e., they maintained their rank-order positions during the stress."

Richtarik, A., Hift, H., Valdivia, E.: "Catecholamines in tissue of guinea pigs subjected to hypoxia." *Arch. Int. Pharmacodyn. Ther.* **159**: 44-47 (1966). F62,068/66

F96,116/68

In guinea pigs, the prolonged respiratory acidosis produced by exposure to 15 percent carbon dioxide in 21 percent oxygen caused a rise in blood corticoids and plasma FFA, with a depletion of adrenal cholesterol and a reduction of lymphopenia.

Sutton, J., Young, J. D., Lazarus, L., Hickie, J. B., Garmendia, F., Velasquez, T.:

"Hormonal response to altitude." *Lancet* December 5, 1970, p. 1194. H32,885/70

In Morococha Peruvian Indians who live at an altitude of 4,540 m. the fasting basal blood STH level is high but does not increase much during physical exercise. By contrast, in normal Australian males performing similar exercise at a simulated altitude of 4,550 m., a striking and sustained increment in serum STH was noted. No change occurred in plasma glucose, insulin or glucagon, but there was a rise in plasma cortisol. After three months of adaptation to high altitude, the hormonal response to exercise was the same as at sea level.

Myles, W. S.: "The excretion of 11-hydroxycorticosteroids by rats during exposure to altitude." *Int. J. Biometeorol.* **16**: 367-374 (1972). H78,664/72

In rats, at 7,300 m. the excretion of 11-OHCS and catecholamines continued at elevated levels throughout the exposure period.

Hale, H. B., Williams, E. W., Ellis, J. P. Jr.: "Human endocrine-metabolic responses to graded oxygen pressures." *Aerosp. Med.* **44**: 33-36 (1973). G99,503/73

In soldiers, EP and NEP output varied inversely with different oxygen pressures.

Hogan, R. P., Kotchen, T. A., Boyd, A. E., Hartley, L. H.: "Effect of altitude on renin-aldosterone system and metabolism of water and electrolytes." *J. Appl. Physiol.* **35**: 385-390 (1973). J5,657/73

In healthy young males, exposure to a simulated altitude of 12,000 ft. decreased plasma renin activity and urinary aldosterone excretion in proportion to the symptoms of acute mountain sickness that were manifested. It remains to be proved whether these changes are due to stress or to the specific effects of anoxia (45 refs.).

Molteni, A., Zakheim, R. M., Mullis, K. B., Mattioli, L.: "The effect of chronic alveolar hypoxia on lung and serum angiotensin I converting enzyme activity." *Proc. Soc. Exp. Biol. Med.* **147**: 263-265 (1974). H95,543/74

In mice, hypoxia caused elevations in serum and lung angiotensin I converting enzyme, closely related to renal renin granules. "The significance of the stimulation of the renin angiotensin aldosterone system in the response to hypoxia remains unknown. It may be an adjustment to the stress of hypoxia or be necessary to the erythropoietic response."

Koob, G. F., Annau, Z.: "Behavioral and neurochemical alterations induced by hypoxia in rats." *Am. J. Physiol.* **227**: 73-78 (1974). H89,535/74

In rats, hypoxia caused a decrease in the NEP content, but no change in the 5-HT concentration of the forebrain. When electrodes were implanted into the lateral hypothalamus, "self-stimulation rates increased while food and water intake decreased during the first 12 h and subsequently returned toward control levels... The results suggest a time-related activation of central adrenergic neuronal systems during exposure to hypoxia." The observation of a differential effect of hypoxia on NEP and 5-HT agrees with several earlier studies using other stressors (36 refs.).

Hemorrhage

In man as in other mammals, hemorrhage produces the usual manifestations of stress, with a rise in ACTH, corticoid and catecholamine discharge.

Allegedly, in the carp, hemorrhage causes a more pronounced increase in the NEP than in the EP content of the blood. In the Pacific salmon, it elicits a rise in plasma 17-OHCS levels. Hence, fish apparently respond very much like mammals to this stressor.

Hemorrhage can also elicit stress ulcers in various species. In pigs, these are inhibited by cholestyramine (which binds bile acids) as well as by 5-HT antagonists and glucocorticoids, but only under certain circumstances which have not yet been clearly identified.

α -Ethyltryptamine prevents the rise in ACTH secretion produced by hemorrhage in the dog; this is ascribed to the pressor property of the compound.

Hemorrhage

(See also our earlier stress monographs, p. xiii)

Post, R. S., Visscher, P. H., Wiggers, C. J.: "Sequential changes in oxygen consumption during oligemic and normovolemic shock, and their meaning." *Am. J. Physiol.* **153**: 71-80 (1948).

B25,993/48

Studies on dogs in normovolemic and oligemic shock produced by hemorrhage, with or without restoration of the withdrawn heparinized blood, show that reduction of oxygen consumption is not a necessary concomitant of the irreversible shock picture. "Even when body temperature is kept constant oxygen consumption is not a

measure of basal metabolic rate during shock. This is due to the fact that oxygen uptake is predominately affected by reduction in oxygen transport capacity, excessive respiratory effort, and varying degrees of acidosis with accumulation of oxygen debt."

Hume, D. M., Nelson, D. H.: "Adrenal cortical function in surgical shock." *Surg. Forum* **5**: 568-575 (1954). E40,942/54

In the dog, surgical trauma markedly increases the 17-OHCS content of adrenal venous blood over that of convalescent animals in which ACTH secretion drops considerably and shows intermittent variations. The cortex maintains high corticoid levels in severe shock despite substantially reduced blood flow, but when the blood pressure drops below 35 mm. Hg adrenal blood flow becomes so low that corticoid output is significantly diminished unless blood transfusions overcome the hypotension. Hemorrhage can increase corticoid output even above the level seen in surgical shock.

Mazeaud, M.: "Influence de divers facteurs sur l'adrénalinémie et la noradrénnalénémie de la carpe" (The influence of different factors on blood adrenaline and noradrenaline in the carp). *C.R. Soc. Biol. (Paris)* **158**: 2018-2021 (1964).

F36,962/64

In the carp, muscular activity and hypoxia cause a slight increase in the EP and a marked rise in the NEP content of the blood. The latter values also rise considerably after hemorrhage and trauma.

Hane, S., Robertson, O. H., Wexler, B. C., Krupp, M. A.: "Adrenocortical response to stress and ACTH in Pacific salmon (*Oncorhynchus tshawytscha*) and steelhead trout (*Salmo gairdnerii*) at successive stages in the sexual cycle." *Endocrinology* **78**: 791-800 (1966).

F63,818/66

In the Pacific salmon (*Oncorhynchus tshawytscha*), plasma 17-OHCS concentrations rose at various phases of migration upstream during the spawning season as well as after bleeding, confinement in a tank or treatment with ACTH. Spawning steelhead trout (*Salmo gairdnerii*) showed an even greater increase in plasma corticoids than did spawning salmon after ACTH injection.

Ganong, W. F., Boryczka, A. T., Lorenzen, L. C., Egge, A. S.: "Lack of effect of α -ethyltryptamine on ACTH secretion when blood pressure is held constant." *Proc. Soc.*

Exp. Biol. Med. **124**: 558-559 (1967).

F77,622/67

In dogs, the increased ACTH secretion produced by hemorrhage is prevented by α -ethyltryptamine in doses which restore the blood pressure. Presumably, it is the pressor effect of α -ethyltryptamine that causes the inhibition of ACTH secretion.

Kies, C., Fox, H. M., Williams, E. R.: "Time, stress, quality, and quantity as factors in the nonspecific nitrogen supplementation of corn protein for adult men." *J. Nutr.* **93**: 377-385 (1967).

H6,953/67

In man, nitrogen retention after the stress of hemorrhage can be improved by a nitrogen-supplemented corn diet, but a similarly supplemented milk diet is even more effective.

Carey, L. C., Sapira, J. D., Curtin, R. A.: "Hemorrhage as a stimulus to adrenal epinephrine secretion." *Bull. Soc. Int. Chir.* **31**: 393-401 (1972).

Dottke, R. B.: "Intrapartaler Blutverlust und Stress Syndrom" (Hemorrhage during delivery and the stress-syndrome), p. 63. Thesis, University of Berlin, 1972.

J16,430/72

A detailed description of the G.A.S. and personal observations on the increase in glucocorticoid elimination following delivery, especially when associated with severe hemorrhage (149 refs.).

Beard, J. D., Knott, D. H., Simpson, J. R., Sargent, W. Q.: "Cardiovascular response to hemorrhage in dogs after alcohol." *Q. J. Stud. Alcohol* **34**: 1303-1314 (1973).

J9,037/73

In dogs, mortality owing to repeated hemorrhage was considerably higher after daily gavages of ethanol solution than following treatment with isocaloric glucose solution. This decrease in resistance may be due to depletion of cardiac reserve caused by stress, but other stressors have not yet been examined under similar circumstances.

Menguy, R., Desbaillets, L., Masters, Y. F.: "Mechanism of stress ulcer: influence of hypovolemic shock on energy metabolism in the gastric mucosa." *Gastroenterology* **66**: 46-55 (1974).

J9,756/74

Experiments on the production of stress ulcers by hemorrhage in rabbits "suggest that the extraordinary vulnerability of gastric mucosal energy metabolism to shock-induced ischemia results from this tissue's

lack of glycogen (not described previously) and its relative inability to utilize anaerobic glycolysis as an alternate source of energy. We propose that a profound decrease in energy metabolism in the gastric mucosa is the cause of the rapid cellular necrosis occurring in this tissue during hypovolemic shock."

Leise, E. M., LeSane, F., Gray, I.: "Lymphocyte and polymorphonuclear enzymes in stress. III. Variations resulting from multiple bleedings and source of New Zealand white rabbits." *Biochem. Med.* **9**: 193-205 (1974).

J11,684/74

Norton, L., Mathews, D., Avrum, L., Eisenman, B.: "Pharmacological protection against swine stress ulcer." *Gastroenterology* **66**: 503-508 (1974). J12,432/74

In pigs, hemorrhagic shock induces stress ulcers in the stomach that can be prevented by cholestyramine (which binds bile acids), methysergide (a 5-HT antagonist) and methylprednisolone, but only under certain conditions of dosage and timing so that the clinical usefulness of this approach is still problematic.

Menguy, R., Masters, Y. F.: "Mechanism of stress ulcer. IV. Influence of fasting on the tolerance of gastric mucosal energy metabolism to ischemia and on the incidence of stress ulceration." *Gastroenterology* **66**: 1177-1186 (1974). J13,618/74

Fasting greatly sensitized the gastric mucosa of the rabbit to the induction of stress ulcers by hemorrhage. These and many other observations suggest that "stress ulceration complicating hemorrhagic shock results from a gastric mucosal energy deficit due to shock-induced mucosal ischemia."

Alexander, D. P., Britton, H. G., Forsling, M. L., Nixon, D. A., Ratcliffe, J. G.: "Pituitary and plasma concentrations of adrenocorticotrophin, growth hormone, vasopressin and oxytocin in fetal and maternal sheep during the latter half of gestation and the response to haemorrhage." *Biol. Neonate* **24**: 206-219 (1974). J14,326/74

By the ninetieth day, the fetal pituitary of sheep can synthesize and store several hormones. Hemorrhage is a potent stimulus for the release of ACTH and arginine vasopressin.

Muscular Exercise

The stressor effect of muscular work has been the subject of particularly careful study for various reasons. It was one of the first agents used to produce a typical stress syndrome, relatively free of any side effects, whose possible specificity could not be easily demonstrated. Furthermore, muscular exercise is associated with numerous activities of daily life such as physical labor, athletics, and even forced restraint (a classic stressor in experimental animals) which inescapably provokes struggle for freedom. Finally, muscular work is one of the most natural and widely applied nonspecific therapeutic measures for the maintenance or rehabilitation of fitness, and resistance to muscular exercise (for example, on a treadmill or a bicycle ergometer) gives us a convenient indicator of stress tolerance.

Physical exercise of sufficient intensity and duration elicits all the characteristic manifestations of the G.A.S. These need not be recapitulated here, since they have been described at length in the various monographs, reviews and original articles abstracted in the following pages.

It may be worth pointing out, however, that the rise in plasma glucose and FFA is not specifically connected with muscular work as such, since it occurs also after the application of other stressors, whereas the strong cardiovascular and respiratory reactions are preponderantly specific adaptive responses to muscular contraction.

The ability of muscular work to produce a discharge of catecholamines, ACTH and glucocorticoids, as well as the metabolic consequences of these hormonal responses, have been extensively described. It is of some historical interest that probably the

first demonstration of corticoid excretion during stress was based on corticoid determinations in the urine of horses before and after a race.

In rats, swimming to exhaustion depletes brain 5-HT and NEP. This appears to be related to stress but is not reproduced by all stressors tested. Both exercise and EP diminish insulin secretion.

In man, plasma STH often rose during physical exercise whereas insulin levels remained unchanged or decreased. EP did not cause a similar release of STH. The failure of plasma insulin levels to rise in response to exercise-induced hyperglycemia is consistent with the finding that EP impairs insulin release. Hard work on a bicycle ergometer increased plasma NEP, FFA and lactate levels, but there was no strict correlation between these variables.

Although a relatively "pure" stressor, muscular exercise is also always modified in its effects by conditioning factors. Those factors inherent in muscle work (for example, energy metabolism, cardiovascular and respiratory adjustments) are readily identified, whereas others can be recognized only by special investigations.

Genetic factors can greatly influence susceptibility to the stressor effect of muscular work, as shown by the striking differences among various species of animals and even different individuals within the same species. In the carp, muscular activity causes only a slight increase in the EP but a pronounced rise in the NEP level of the blood. Contrary to expectations, wild and domesticated mice withstood forced swimming about equally well. The plasma cortisol rise produced by exercise in the horse does not strictly parallel the degree of eosinopenia, but essentially, adrenocortical function in this species is similar to that in other mammals.

The ambient temperature also has a marked effect, especially in that work in very cold or very hot places is particularly stressful. For example, in mine workers, a standard exercise which normally caused no significant change in blood cortisol elicited a pronounced rise in hot surroundings.

Limitation of food intake greatly sensitizes the rat to the induction of gastric ulcers by forced muscular work. Hence, this combination of agents is often used for the standard production of stress ulcers.

In men over forty-five years of age, a standardized bicycle ergometer test causes more pronounced platelet aggregation than in controls of less than twenty-two years. This fact may play a part in the well known age-dependence of predisposition to thromboembolic processes.

Muscular Exercise

(See also our earlier stress monographs, p. xiii)

Generalities. Andersen, D. H.: "The effect of food and of exhaustion on the pituitary, thyroid, adrenal and thymus glands of the rat." *J. Physiol. (Lond.)* 85: 162-167 (1935). 32,606/35

In rats, forced exercise causes adrenal enlargement and thymus atrophy. The latter "suggests accidental involution, but characteristic histological changes are not found." [The functional relationship between these alterations has not yet been suspected but

they are compared with other corresponding changes seen during estrus (H.S.).]

Holmes, T. H., Wolff, H. G.: "Life situations, emotions and backache." In: Wolff, H. G., Wolf, S. G., et al., *Life Stress and Bodily Disease*, pp. 750-772. Baltimore: Williams & Wilkins, 1950. B51,943/50

Increased generalized skeletal muscle hyperfunction along with electric activity was "part of an individual's reaction to a threatening life situation engendering conflict, anxiety and other strong emotions and was often provocative of pain in the back, neck, and extremities."

Edholm, O. G., Bacharach, A. L. (eds.): *The Physiology of Human Survival*, p. 581. New York and London: Academic Press, 1965. E6,283/65

A monograph on human reactions to various stressors such as heat, cold, anoxia, high altitudes, compression and decompression, nutritional damage, sleep deprivation, monotony, fatigue, emotional arousal and muscular exercise. Each chapter is written by a specialist in the corresponding field, and numerous references indicate the difference between specific defense mechanisms and the stressor effect of the agents used.

Levitt, R. A., Webb, W. B.: "Effect of infantile treadmill experience on body-weight and resistance to exhaustion in the rat." *Nature* **208**: 1128-1129 (1965).

F58,465/65

Rats forced to run in a treadmill during the first few weeks of life initially lost weight but then grew better than the controls and became much more resistant to exhaustion. "It appears that the treadmill acted as a stressor and that this 'acute stress' during infancy was responsible for the increased growth of muscle and other tissue. It is not known whether the improved treadmill performance is indicative of a general increased resistance to stress or is a specific effect of the early treadmill experience."

Connell, A. M., Cooper, J., Redfearn, J. W.: "The contrasting effects of emotional tension and physical exercise on the excretion of 17-ketogenic steroids and 17-ketosteroids." *Acta Endocrinol. (Kh.)* **27**: 179-194 (1958). C47,363/58

In a group of medical students, the psychogenic stress of an important examination significantly increased 17-KGS and slightly raised 17-KS excretion. Muscular activity (treadmill exercise, route march) elicited a

moderate decrease in 17-KS and no marked change in 17-KGS elimination. "It is suggested that emotional stress causes an increase in the formation of adrenal cortical hormones; this formation is in preparation for the physical stress and effort which, under 'natural' conditions, could be expected to follow on the initial emotional strain."

Hasselman, M., Schaff, G., Metz, B.: "Influences respectives du travail, de la température ambiante et de la privation de sommeil sur l'excrétion urinaire de catécholamines chez l'homme normal" (Influence of work, ambient temperature and sleep deprivation on urinary catecholamine secretion in normal men). *C.R. Soc. Biol. (Paris)* **154**: 197 (1960). C88,413/60

In people performing multiple choice psychomotor muscular work, catecholamine excretion rose; this effect was particularly pronounced following periods of sleep deprivation.

Frenkl, R., Csalay, L.: "Effect of regular muscular activity on adrenocortical function in rats." *J. Sports Med. Phys. Fitness* **2**: 207-211 (1962). J12,182/62

Barchas, J. D., Freedman, D. X.: "Brain amines: response to physiological stress." *Biochem. Pharmacol.* **12**: 1232-1238 (1963). E29,915/63

In rats, swimming to exhaustion especially in cold water caused depletion of brain 5-HT and NEP. Similar changes could not be obtained by having them run in a revolving cage, for under the conditions of the experiment the rats soon gave up and just allowed themselves to be dragged. On the other hand, immersion in cold water did reproduce the catecholamine depletion, whereas several other stressors (electroshock, starvation, hypoxia, surgery, adrenalectomy) were ineffective in this respect. The response is not dependent upon the pituitary-adrenocortical system since active stressors deplete brain catecholamines even after hypophysectomy, as does LSD. It is noteworthy that drugs that induce a similar change in brain amines produce a unique pattern of central excitation, acting on brain mechanisms concerned with metabolic and physiologic temperature regulation. "If the stressors have such a central action, a role for the biogenic amines in central as well as in peripheral aspects of temperature regulation should be sought."

Mazeaud, M.: "Influence de divers facteurs sur l'adrénalénémie et la noradrénalénémie de la carpe" (The influence of dif-

ferent factors on blood adrenaline and noradrenaline in the carp). *C.R. Soc. Biol. (Paris)* **158**: 2018-2021 (1964).

F36,962/64

In the carp, muscular activity and hypoxia cause a slight increase in the EP and a marked rise in the NEP content of the blood. The latter values also rise considerably after hemorrhage and trauma.

Schalch, D. S.: "The influence of physical stress and exercise on growth hormone and insulin secretion in man." *J. Lab. Clin. Med.* **69**: 256-269 (1967). G44,274/67

Human plasma STH often rose during periods of physical stress or exercise while insulin values remained unchanged or were decreased. EP did not reproduce the release of STH. The failure of plasma insulin levels to rise in response to stress-induced hyperglycemia is consistent with the finding that EP infusion impairs insulin discharge. Plasma glucose and FFA levels rose as expected during physical exercise. Presumably, certain stressors are diabetogenic not only because of EP and corticoid release but also because of a discharge of STH on the one hand, and an EP-induced suppression of insulin secretion on the other.

Wright, P. H., Malaisse, W. J.: "Effects of epinephrine, stress, and exercise on insulin secretion by the rat." *Am. J. Physiol.* **214**: 1031-1034 (1968). F97,956/68

In rats, various stressors (EP, swimming, electroshock) diminish insulin secretion. "It is suggested that endogenous epinephrine released during stress or exercise is sufficient to suppress insulin secretion even under conditions of hyperglycemia" (29 refs.).

Bellet, S., Roman, L., Barham, F.: "Effect of physical exercise on adrenocortical excretion." *Metabolism* **18**: 484-487 (1969).

H13,622/69

After a brief review of the literature on increased corticoid excretion under the influence of psychogenic stressors, personal observations are reported showing that, in healthy young students, even moderate exercise on a treadmill suffices to raise urinary 11-OHCS elimination.

tem during exercise in men: relation to work load and physical working capacity." *Bull. Acad. Pol. Sci. Cl. 2 No. 20*: 897-901 (1972). H80,315/72

In man, hard work on a bicycle ergometer increased plasma NEP, FFA and lactate levels, but there was no strict correlation among these changes.

Jobin, M., Dulac, S.: "Effets aigus et chroniques de l'exercice sur l'activité hypophyso-thyroiđosurrénaliennes" (Acute and chronic effects of exercise on hypophysis-thyroid-adrenal activity). *Ann. ACFAS* **40**: 128 (1973). H87,896/73

In rats, chronic forced exercise caused adrenal enlargement in association with an increase in plasma TTH. In man, after ten weeks of muscular training plasma T4 was diminished without any significant change in plasma T3 although the latter exhibited an initial rise. These and other observations suggest an acceleration of T4 metabolism followed by an increment in its secretion.

H87,465/74

In rats "an attempt was made to evaluate the possible role of *Na-K-ATPase* in the mechanism of depression of potassium transport against its electrochemical gradient after chronic physical overload. In comparison with normal response of the heart, both morphological and biochemical changes were diminished in both the trained and, to a smaller extent, the overtrained heart during acute extreme exertion. It is concluded that potassium accumulation in myocardial cells is an essential adaptive reaction to physical exertion and the extent of potassium uptake depends on the functional state of the heart."

Lopez-S., A., Vial, R., Balart, L., Arroyave, G.: "Effect of exercise and physical fitness on serum lipids and lipoproteins." *Atherosclerosis* **20**: 1-9 (1974). H87,491/74

During physical training there was a decrease in serum triglycerides, pre-β-proteins and α-lipid proteins in healthy young students. The serum cholesterol levels showed comparatively little change.

Struck, P. J., Tipton, C. M.: "Effect of acute exercise on glycogen levels in adrenalectomized rats." *Endocrinology* **95**: 1385-1391 (1974). H94,156/74

+Varia. Foss, C. R., Horvath, S. M.: "Reactions of wild and albino mice in response to forced swimming." *Proc. Soc. Exp. Biol. Med.* **120**: 588-592 (1965).

F59,402/65

The ability of wild and domestic albino mice to swim until exhaustion was much shorter in water at 20° C than at 37° C. The drop in colonic temperature was an excellent indication of exhaustion in temperatures of 28° C or less but remained normal or even rose at higher temperatures. There was no significant difference either in colonic temperature or in endurance between the two strains.

James, V. H. T., Horner, M. W., Moss, M. S., Rippon, A. E.: "Adrenocortical function in the horse." *J. Endocrinol.* **48**: 319-335 (1970). H32,502/70

In the horse, *surgical trauma* or *hypoglycemia* increases plasma cortisol levels, whereas exercise is much less effective in this respect. The cortisol variations are not necessarily associated with changes in the eosinophil count. "It is concluded that the mechanisms of control of adrenocortical function in the horse are not dissimilar to those described for other mammalian species."

Wyndham, C. H.: "The physiology of exercise under heat stress." *Annu. Rev. Physiol.* **35**: 193-220 (1973). H67,021/73

A review on the physiology of muscular exercise "under heat stress," with special reference to metabolic and vascular reactions. Very little attention is given to stress in general or to adaptive hormones (122 refs.).

Scheele, K., Müller, K. M., Böhm, B., Westphal, G.: "Morphologische Funktionsstudien an Thrombozyten während und nach dosierter Ergometerbelastung in verschiedenen Altersstufen" (Morphologic studies on thrombocyte function during and after standardized bicycle ergometer tests in different age groups). *Dtsch. Med. Wochenschr.* **99**: 252-255 (1974). H82,593/74

When subjected to a standardized bicycle ergometer test, older men (forty-five years) had a greater tendency toward platelet aggregation than did younger men (22 years).

Lasting platelet aggregation after such "physical stress" was demonstrable only in the older age group. It is concluded that "regular physical activity is indicated in order to avoid thromboembolic episodes during or after sudden physical stress in persons of the older age groups." The authors emphasize that such platelet aggregation may be due to a discharge of EP which would raise ADP, a substance that plays a prominent role in platelet aggregation. The phenomenon appears to be characteristic of the alarm reaction, but it is impossible to ascertain whether psychic stimulation or the muscular activity is of primary causal significance.

Pintar, K., Schulte, W. J., Barboriak, J. J.: "Histologic study of gastric lesions in food-restricted rats." *Proc. Soc. Exp. Biol. Med.* **145**: 1353-1358 (1974). H86,412/74

"Rats limited to food intake of one hour a day and allowed to run in an activity wheel developed gastric lesions which on histologic examination resembled human stress ulcers."

Johnson, T. H., Tharp, G. D.: "The effect of chronic exercise on reserpine-induced gastric ulceration in rats." *Med. Sci. Sports* **6**: 188-190 (1974). J16,755/74

A study on cross-resistance in rats, using reserpine-induced gastric ulcers as an indicator of stress, and having them run in a treadmill or swim as a second stressor. "The degree of ulceration of the glandular portion of the stomach produced by administration of reserpine was significantly lower in treadmill runners than in their controls, however, the degree of ulceration for the swimmers was not significantly different from that of their controls.... It might be that the swimmers were still in Selye's 'stage of resistance' and not quite in the 'trained state.' Thus, the corticosterone level may have still been higher than normal and may have contributed to the increased ulceration in the swimmers" (19 refs.).

Restraint

Physical restraint has been one of the most popular stressors in experimental medicine. The very first investigations of the alarm reaction were performed on rats immobilized in a way that denied them free motion by use of shackles of soft tape to prevent them from incurring self-inflicted injury from struggling. In addition, their heads were fixed in a position which made it impossible for them to chew away their fetters and incidentally traumatize their limbs. In this manner, we hoped to produce the purest stress of frustration by depriving the animals of their liberty to move about. Actually, further investigations showed that even this stressor is complex. The immobilization is accompanied by strong struggling which means muscular exercise, and at the same time thermoregulation is impeded by stretching out the animals and preventing them from huddling together.

Various modifications of the apparatus used for confinement have been designed, for example, tubular enclosures and wire cages for small rodents, or restraint chairs for primates.

Restraint proved to be very effective in eliciting typical nonspecific stress manifestations, such as: thymicolympathic and splenic atrophy, polymorphonuclear leukocytosis, eosinopenia, lymphopenia, gastroduodenal ulcers, and both morphologic and functional signs of adrenocortical hyperactivity with a discharge of medullary catecholamines. If prolonged, the stress of constraint also causes a drop in body temperature and loss of weight of all organs except the adrenal cortex.

Repeated restraint produced degranulation of the pancreatic β -cells in the rat and atrophy of the excretory parenchyma with the exception of small "halos" around the Langerhans islets. The mechanism of this latter change has still not been clarified, although it was among the first morphologic signs of the alarm reaction to be described.

The so-called restraint ulcers have been the subject of particularly intense investigations because of the great clinical importance of stress-induced gastric erosions. They will be reconsidered at length in the section on Experimental Diseases of Adaptation.

The fact that immobilization causes hemorrhagic mucosa ulcerations in the stomach, the duodenum, and sometimes even in the upper small intestine was one of the first observations made in establishing "the classical triad of the alarm reaction," consisting of these ulcers in combination with thymicolympathic involution and adrenocortical hyperactivity. Ever since that time these changes have received considerable attention as readily determined and very reliable indicators of stress, especially during the acute phase of the alarm reaction.

It was also one of our first findings that immobilization (like other stressors) produced no thymicolympathic involution or other manifestations of increased ACTH and glucocorticoid secretion after adrenalectomy; however, the restraint ulcers were in fact more than normally severe in animals deprived of their adrenals. In this respect, glucocorticoid substitution therapy, at maintenance dose levels, actually exerted a protective effect. On the other hand, a heavy overdose of glucocorticoids predisposes to peptic ulceration and delays healing even in intact animals. However, it is difficult to explain why, under certain circumstances, prednisolone may offer some protection against restraint ulcers in the rat.

These early findings have been described at length in our monographs on stress (see Reviews) and will not be included in the annotated bibliography at the end of this section. There, we shall limit ourselves to more recent confirmatory data showing that

restraint ulcers can also be produced in various species other than the rat, including the rabbit, mouse, guinea pig, hamster, monkey and even fish.

It is especially noteworthy that these ulcerations are markedly aggravated by a cold surrounding temperature as well as by drugs (for example, reserpine) which decrease the body temperature in the rat. The combination of immobilization plus cold has therefore developed into one of the most commonly employed models for the production of stress ulcers.

Young rats are more sensitive to restraint ulcers than are old animals.

The data on the possible protective effect of bilateral vagotomy are somewhat contradictory.

In rats, EP, like atropine and other anticholinergic drugs, inhibited the development of restraint ulcers, as did chlorpromazine, benactyzine, and pentobarbital; acetazolamide was inactive in this respect.

α -Methyldopa, bretylium, phenoxybenzamine, and phentolamine also reduced the incidence of restraint ulcers in the rat. From these observations it was concluded that an increased turnover of NEP may be causally related to the development of ulcerations.

Nicotinic acid prevents restraint ulcers in fasted rats even more effectively than does chlorpromazine.

According to some investigators, diazepam pretreatment or vagotomy inhibits restraint ulcers to some extent in the rat, but combined application of these agents offers the best protection. The effects of diazepam are ascribed to its action on the vegetative centers in the hypothalamic and limbic systems, leading to a partial inhibition of vagally controlled hydrochloric acid and pepsin secretion.

According to one report, restraint ulcers in the rat are often associated with hydrothorax; overnight fasting prevents the hydrothorax but reduces gastric ulceration, in contradiction to most other observations. Some protection was also obtained by crowding of the animals and a rise in ambient temperature. In fact, crowding may have increased the body temperatures of the animals.

If rats are immobilized during the active period of the circadian cycle, stress ulcers develop more easily than during the inactive period.

Food deprivation is a particularly powerful sensitizer for the production of restraint ulcers. Hence, all experiments with agents which depress appetite must be carefully examined to establish whether these stimuli are effective as such or merely diminish caloric intake. For further discussion of specific factors affecting restraint ulcers by their direct pharmacologic effect upon the gastric mucosa and its secretions, the reader is referred to the original articles quoted at the end of this section.

In constrained rats, unpredictable electric shocks produced a higher incidence of gastric ulcers than did predictable shocks.

Supine exercise during prolonged bedrest was tested for its effect upon urinary cortisol and catecholamine excretion in a small group of healthy young men. The results suggested that "exercise could decrease the severity of deconditioning" under these circumstances, but the number of observations is insufficient to draw any definite conclusions.

The effect of confinement is conditioned by numerous agents. Many of them have already been discussed in relation to conditioning for "restraint ulcer" formation, which has been the topic of the most intensive investigations. Exposure to cold is particularly damaging to immobilized animals (as shown especially in rats and rabbits), perhaps

because restraint, in itself, tends to lower body temperature, and exogenous cooling has an additive effect.

Possibly, reserpine, which likewise causes hypothermia, sensitizes the rat to the stressor action of constraint for the same reason. The muscle-relaxing effect of zoxazolamine is enhanced by the stress of physical limitation, especially in cold environments.

In guinea pigs, overheating reduced the adrenal cortical response to the stress of restraint without altering reactivity to exogenous ACTH.

The tumorigenic action of murine sarcoma virus is allegedly increased by immobilization of the rat, perhaps by interference with immunologic defense as a consequence of the stress-induced thymus involution.

Genetic predisposition may alter sensitivity to restraint, and this stressor has been found to be effective in various species of mammals, and even in fish, as shown by the rise in plasma cortisol produced by constraint in the carp.

In rabbits, immobilization causes a rapid rise in blood pressure, and the same is true in other species.

EEG studies suggest that homeostatic mechanisms mediated by the mesencephalic reticular formation and gray matter are the principal regulators of blood pressure and renin release under these circumstances.

Understandably, the greatest emphasis was placed upon changes in adaptive hormone production as a consequence of restraint, but these deserve no special consideration since they are essentially the same as those elicited by other stressors.

Restraint

(See also our earlier stress monographs, p. xiii)

Generalities. Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* 17: 234-248 (1936). 36,032/36

First detailed description of the "alarm reaction" characterized by adrenocortical enlargement with acute loss of lipids, thymicolumphantic atrophy and decreased body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for forty-eight hours or more, large doses of atropine, morphine, formaldehyde or EP). Adrenalectomy and to a lesser extent hypophysectomy prevent the thymus involution. "The changes caused by a drug when it is given for the first time will subside later in spite of the continued administration of this drug" but greatly shorten survival. Perhaps the adrenal enlargement, loss of body weight and other manifestations of the alarm reaction enable the organism "to meet critical situations more efficiently."

Renaud, S.: "Improved restraint-technique for producing stress and cardiac necrosis in

rats." *J. Appl. Physiol.* 14: 868-869 (1959). C62,636/59

Pfeiffer, C. J.: "The physiologic effects of restricted activity in the rat: stress effects of chronic restraint." *Exp. Med. Surg.* 25: 201-217 (1967). H1,775/67

Dost, F. N., Johnson, D. E., Wang, C. H.: "A restraint system for squirrel monkeys." *Lab. Anim. Sci.* 22: 893-897 (1972). H79,351/72

Description of a chair for the restraint of squirrel monkeys, which permits comfortable confinement for periods of several days.

→**Hormones.** Kvetňansky, R., Mikulaj, L.: "Adrenal and urinary catecholamines in rats during adaptation to repeated immobilization stress." *Endocrinology* 87: 738-743 (1970). H30,286/70

In rats subjected to repeated restraint, the gradual diminution of urinary catecholamine excretion after each stress experience is attributed to "an enhanced ability to replace the released catecholamine rather than to a diminished catecholamine release after repetition of this stress."

Perhach, J. L. Jr., Barry, H.: "Stress responses of rats to acute body or neck re-

straint." *Physiol. Behav.* **5**: 443-448 (1970).
G77,139/70

In rats, blood corticoid increases were noted after various types of restraint.

Kvetňanský, R., Weise, V. K., Gewirtz, G. P., Kopin, I. J.: "Synthesis of adrenal catecholamines in rats during and after immobilization stress." *Endocrinology* **89**: 46-49 (1971). H43,006/71

Immobilization is known to augment tyrosine hydroxylase in rat adrenals. It could now be shown that "the increased levels of enzymes result in enhanced synthesis of epinephrine-¹⁴C from tyrosine-¹⁴C but not from dopa-³H. During immobilization, conversion of tyrosine-¹⁴C to catecholamines is further increased and may exceed the capacity of even the elevated levels of dopamine- β -hydroxylase to convert dopamine to norepinephrine."

Brown, G. M., Schalch, D. S., Reichlin, S.: "Patterns of growth hormone and cortisol responses to psychological stress in the squirrel monkey." *Endocrinology* **88**: 956-963 (1971). H37,353/71

In squirrel monkeys, various stressors (capture, chair restraint, intense sound, and aversive conditioning) increase plasma STH and cortisol levels, but the two responses do not run parallel and are presumably regulated by different mechanisms. In the case of chair restraint, STH values fall to resting levels whereas cortisol continues to rise.

Euker, J., Meites, J., Riegle, G.: "Serum LH and prolactin following restraint stress in the rat." *Physiologist* **16**: 307 (1973). H73,456/73

In rats, restraint increased serum LTH levels, whereas the proestrus surge of LH was blocked by this stressor.

Leach, C. S., Hulley, S. B., Rambaut, P. C., Dietlein, L. F.: "The effect of bedrest on adrenal function." *Space Life Sci.* **4**: 415-423 (1973). J9,311/73

In a very small group of healthy young men, the stressor effect of prolonged bedrest, with or without supine exercise, was tested using urinary cortisol and catecholamines as indicators. The "data suggest that exercise could decrease the severity of deconditioning caused by bedrest." [The number of subjects is too small for statistical evaluation (H.S.).]

Riegle, G. D.: "Chronic stress effects on adrenocortical responsiveness in young and aged rats." *Neuroendocrinology* (Basel) **11**: 1-10 (1973). H67,112/73

Young and old rats were subjected to repeated restraint for twenty days. The decrease in stress responsiveness was greater in the former than in the latter groups.

Yanase, M.: "A study on the role of brain for the establishment of adaptation to the repeated immobilization stress. II. A role of the limbic-midbrain system in the repeated immobilization stress." *J. Physiol. Soc. Jap.* **35**: 171-178 (1973) (Japanese). J17,716/73

In rabbits, ACTH release following repeated restraint diminished as a consequence of adaptation. This was not found after sectioning of the fornix. "Therefore, hippocampal inhibition of ACTH release is considered to correlate with the inhibition of ACTH release under the repeated stress, and hippocampus may play an important role in the establishment of adaptation to the stress."

Zachariasen, R. D., Newcomer, W. S.: "Phenylethanolamine-N-methyl transferase activity in the avian adrenal following immobilization or adrenocorticotropin." *Gen. Comp. Endocrinol.* **23**: 193-198 (1974). H88,608/74

In cockerels, ACTH or immobilization resulted in an increase in plasma EP and NEP with an accompanying decrease in the adrenal levels of these catecholamines; plasma corticosterone also rose as did the phenylethanolamine-N-methyl transferase (PNMT) content of the adrenals without affecting adrenal corticosterone. "It is suggested that the rapid increase in PNMT activity, occurring with the acute application of stressors in chickens, may provide a means of sustaining an increased outflow of EP in times of 'stress.'" Corticosterone may play a role in the elevation of PNMT during the avian stress response.

→Enzymes and Other Metabolites.
Bartlett, R. G. Jr., Miller, M. A.: "The adrenal cortex in restraint hypothermia and in adaptation to the stress of restraint." *J. Endocrinol.* **14**: 181-187 (1956). C25,043/56

In rats, mild restraint for one week increased the ascorbic acid and to a lesser extent the cholesterol content of the adrenals. Restraint, sufficiently severe to reduce body temperature, produced inverse changes. Loss of adrenal cholesterol and ascorbic acid from the adrenals was particularly severe in animals restrained while exposed to cold.

Buchel, L., Liblau, L., Murawsky, M., Prioux-Guyonneau, M.: "Influence de sub-

stances psychotropes sur les variations du taux plasmatique des acides gras libres chez le rat constraint" (Influence of psychotropic substances on variations of total plasma free fatty acids in restrained rats). *Arch. Sci. Physiol.* **23**: 407-414 (1969). G68,704/69

In rats, restraint severe enough to cause gastric ulcers diminishes the FFA content of the plasma, contrary to most other stressors.

Kvetnansky, R., Weise, V. K., Kopin, I. J.: "Elevation of adrenal tyrosine hydroxylase and phenylethanolamine-N-methyl transferase by repeated immobilization of rats." *Endocrinology* **87**: 744-749 (1970).

H30,287/70

Sobocińska, J.: "The effect of prolonged immobilization on diuresis and water intake in rats." *Space Life Sci.* **4**: 200-203 (1973).

H79,375/73

In rats immobilized in their natural position for many weeks, there was an increase in diuresis but no changes in sodium or potassium excretion.

Zachariasen, R. D., Newcomer, W. S.: "Phenylethanolamine-N-methyl transferase activity in the avian adrenal following immobilization or adrenocorticotropin." *Gen. Comp. Endocrinol.* **23**: 193-198 (1974).

H88,608/74

In cockerels, ACTH or immobilization resulted in an increase in plasma EP and NEP with an accompanying decrease in the adrenal levels of these catecholamines; plasma corticosterone also rose as did the phenylethanolamine-N-methyl transferase (PNMT) content of the adrenals without affecting adrenal corticosterone. "It is suggested that the rapid increase in PNMT activity, occurring with the acute application of stressors in chickens, may provide a means of sustaining an increased outflow of EP in times of 'stress.'" Corticosterone may play a role in the elevation of PNMT during the avian stress response.

→Varia. Elmadjian, F., Pincus, G.: "The adrenal cortex and the lymphocytopenia of stress." *Endocrinology* **37**: 47-49 (1945).

B366/45

In mice, both restraint and cold produce a typical stress lymphocytopenia.

Marsh, J. T., Rasmussen, A. F. Jr.: "Response of adrenals, thymus, spleen and leucocytes to shuttle box and confinement stress." *Proc. Soc. Exp. Biol. Med.* **104**: 180-183 (1960).

C89,538/60

"Changes in organ weights and leucocytes following daily exposure to emotionally disturbing shuttle box or confinement stress were consistently observed. Adrenal hypertrophy and drops in circulating leucocytes were relatively rapid with significant changes observed following 3 to 7 days of stress. Involution of thymus and spleen occurred more slowly, with differences becoming maximum following 14 to 28 days of stress. Differences between experimental and control values returned to non-significant levels in 21 days following termination of stress."

Portugalov, V. V., Kaplanskii, A. S., Durnova, G. N.: "The condition of immunocompetent organs in the presence of hypokinesia." *Vestn. Akad. Med. Nauk SSR* **26** No. 10: 29-34 (1971) (Russian). [Eng. transl.: *Vestn. USSR Acad. Med. Sci.* **26**: 40-46 (1971).] J20,535/71

The thymicolympathic and splenic involution associated with stress (restraint) is accompanied by a decrease in the production of immunocompetent cells, but this paradoxically fails to diminish the antibody content of the blood.

Whittaker, D. K., Wilson, T. R.: "The effect of age and strain differences on the incidence of restraint-induced oral and gastric ulcers in three strains of rats." *J. Dent. Res.* **51**: 619-625 (1972). J19,863/72

In different strains of rats, the stress of restraint may cause predominantly *gastric* or *oral ulcers*. The clinical literature suggesting that ulcerative gingivitis, chronic periodontitis, and herpes labialis may also be related to stress in man is reviewed.

Tsukiyama, H., Otsuka, K., Kyuno, S., Fujishima, S., Kijima, F.: "Influence of immobilization stress on blood pressure, plasma renin activity and biosynthesis of adrenocorticoid." *Jap. Circ. J.* **37**: 1265-1270 (1973). H81,677/73

In rabbits, "shortly after the beginning of immobilization stress a remarkable elevation in the *arterial pressure*, a significant increase in plasma renin levels and plasma corticosterone concentrations were observed." However the changes in plasma renin and corticosterone did not run parallel, and hence there appear to be different mechanisms activating the renin-angiotensin and pituitary-adrenocortical systems. EEG studies suggest that the homeostatic mechanisms mediated by the mesencephalic reticular formation and grey matter regulate blood

pressure and renin release while the hippocampus, amygdala and anterior hypothalamic area are less effective in this respect. Findings from selective electric stimulation of various brain areas are in accordance with this interpretation.

Moritz, V., Baumann, R., Hecht, K., Poppei, M., Treptow, K.: "Relationen zwischen neurotisch induzierter Blutdruckdysregulation und Granulagehalt der Pankreas-B-Zellen bei der Albinoratte" (Relation between neurosis-induced blood pressure dysfunction and granule content in the pancreatic β -cells of the albino rat). *Acta Biol. Med. Ger.* **30**: 231-240 (1973).

J7,756/73

Under certain circumstances, repeated restraint can cause degranulation of pancreatic β -cells in the rat. This change is ascribed to stress.

Metz, G., Classen, H. G., Vogel, W., Mittermayer, C.: "Sympathico-adrenerge Stimulation und Lungenveränderungen" (Sympathico-adrenergic stimulation and pulmonary changes) (abstracted). *5th Europ. Congr. Anaesthesiology*, p. 202. Madrid, 1974.

J18,264/74

In rats, the stress of restraint causes edema and disseminated hemorrhages in the lungs which can be prevented by certain α -adrenergic blocking agents and analgesics.

+Varia. Lange, K., Gold, M. M. A., Weiner, D., Kramer, M.: "Factors influencing resistance to cold environments." *Bull. U.S. Army* **8**: 849-859 (1948).

B23,962/48

The survival time of restrained rabbits is greatly diminished at -20°C and their body temperature drops precipitously.

Frankel, H. M.: "Effects of restraint on rats exposed to high temperature." *J. Appl. Physiol.* **14**: 997-999 (1959).

J11,919/59

Restraint diminished the resistance of rats to high temperatures, although the final rectal temperatures were not greatly different.

Taylor, R. E. Jr., Fregly, M. J.: "Effect of reserpine on body temperature regulation of the rat." *J. Pharmacol. Exp. Ther.* **138**: 200-207 (1962).

D41,319/62

In rats, reserpine given intraperitoneally diminishes body temperature much more at low than at high environmental temperatures. It acts by decreasing heat production rather than by increasing heat loss. Restraint aug-

ments the reserpine-induced drop in body temperature.

Brodie, D. A., Valitski, L. S.: "Production of gastric hemorrhage in rats by multiple stresses." *Proc. Soc. Exp. Biol. Med.* **113**: 998-1001 (1963).

E28,039/63

"Gastric hemorrhage was produced in 93% of rats subjected to cold + restraint stress for 60 minutes." This combination of stressors also elicited a marked depression of body temperature lasting three hours after the stress. "Anticholinergics, ganglionic blocking agents, certain central nervous system depressants and epinephrine reduced the incidence of hemorrhage."

Ader, R.: "Gastric erosions in the rat: effects of immobilization at different points in the activity cycle." *Science* **145**: 406-407 (1964).

F16,095/64

Ader, R.: "Behavioral and physiological rhythms and the development of gastric erosions in the rat." *Psychosom. Med.* **29**: 345-353 (1967).

H62,749/67

In rats, stress ulcers of the stomach develop much more readily if they are immobilized during the active period (18:00 to 03:00) than during the inactive period of their circadian cycle.

Mikhail, A. A.: "Relationship of conditioned anxiety to stomach ulceration and acidity in rats." *J. Comp. Physiol. Psychol.* **68**: 623-626 (1969).

G68,624/69

In rats, conditioned anxiety did not aggravate the production of stress ulcers by restraint.

Martin, M. S., André, C., Martin, F., Lambert, R.: "Rôle du froid dans l'ulcère de contrainte chez le Rat" (Effects of cold on restraint ulcers in rats). *C. R. Soc. Biol. (Paris)* **163**: 158-161 (1969).

H14,537/69

In rats, restraint at 5°C is highly effective in producing gastric ulcers within three hours and a concurrent drop in rectal temperature.

Noel, W. K., Kilmore, M. A.: "Effect of stress and restricted food intake on corticosteroid-induced ulcers." *J. Am. Osteopath. Assoc.* **69**: 1051-1052 (1970).

J23,510/70

In rats, moderate amounts of cortisol increased the severity of restraint ulcers.

Blaszkowski, T. P., DeFeo, J. J., Guarino, A. M.: "Central vs. peripheral catecholamines in rats during adaptation to chronic restraint stress." *Pharmacology (Basel)* **4**: 321-333 (1970).

H36,516/70

Reserpine pretreatment increases the mortality of rats exposed to the stress of restraint, presumably because of its central rather than peripheral NEP-depleting action.

Prioux-Guyonneau, M.: "Répercussions de la contrainte sur la régulation thermique du rat blanc maintenu à différentes températures ambiantes" (Repercussions of restraint on thermal regulation of white rats kept at different environmental temperatures). *C.R. Soc. Biol. (Paris)* **164**: 72-75 (1970).

J21,917/70

Ritchie, W. P. Jr., Roth, R. R., Fischer, R. P.: "Studies on the pathogenesis of 'stress ulcer': effect of hemorrhage, transfusion, and vagotomy in the restrained rat." *Surgery* **71**: 445-451 (1972).

G89,104/72

"Restraint-induced ulcers in the rat resemble posttraumatic 'stress ulcers' in man in that they are acute and multiple, occur mainly in the stomach, are confined to the oxytic cell area, and are not associated with gastric acid hypersecretion." The production of these ulcers is enhanced by *hemorrhage* and greatly diminished by *vagotomy*.

Buchel, L., Prioux-Guyonneau, M., Liblau, L., Murawsky, M.: "Influence de la contrainte du rat blanc sur l'activité, la pénétration et le métabolisme de l'hexobarbital et du barbital" (Influence of restraint on the activity, penetration and metabolism of hexobarbital and barbital in white rats). *Thérapie* **27**: 609-625 (1972).

G92,849/72

"The potentiation of the hypnotic effects, increase of the sleeping time with *hexobarbital*, shortening of the latent period with *barbital*, in relation with short or long lasting restraint in rats, are attributable to two different mechanisms: inhibition of hexobarbital metabolism; increase of barbital penetration into the brain."

Ivanova, G. N., Altukhova, V. I., Kenig, E. E., Skebelskaia, I. B.: "Functional condition of the adrenal cortex of guinea pigs under conditions of prolonged and continuous overheating." *Probl. Endokrinol. (Mosk.)* **18** No. 5: 98-103 (1972).

H60,926/72

In guinea pigs, *overheating* at 35°C from five hours up to twenty-one days reduced the adrenocortical response to the stress of restraint but did not alter blood 17-OHCS levels or reactivity to exogenous ACTH. "A conclusion could be drawn that reduced response to stress in these animals was as-

cociated with a lesser excretion of endogenous ACTH."

Seifter, E., Rettura, G., Zisblatt, M., Levenson, S. M., Levine, N., Davidson, A., Seifter, J.: "Enhancement of tumor development in physically-stressed mice inoculated with an oncogenic virus." *Experientia* **29**: 1379-1382 (1973).

H80,975/73

In mice, restraint by a partial body cast produced the typical manifestations of systemic stress and at the same time increased susceptibility to the tumorigenic action of murine *sarcoma virus*. In the immobilized animals "there appeared to be a smaller number of small lymphocytes due to stress and a proliferation of epithelioid elements. Hassal bodies were also involved in agreement with earlier findings of Selye. If stress or cortisone treatment result in impaired function of these structures, then the endocrine function of the thymus gland as well as its role in providing circulating cells would be disturbed." In any event, the response of the thymus during stress is assumed to increase susceptibility to the virus through interference with immune reactions.

Yano, S., Harada, M.: "A method for the production of stress erosion in the mouse stomach and related pharmacological studies." *Jap. J. Pharmacol.* **23**: 57-64 (1973).

H85,804/73

In mice, stress ulcers of the stomach can be produced most reliably by immersing them in water of 25°C for eighteen hours while they are enclosed in a restraint cage of special design. The technique is said to be particularly useful in the assay of drugs inhibiting such erosions. Curiously, immersion at lower or higher temperatures causes less severe gastric ulcers.

Buchel, L., Murawsky, M.: "Métabolisme et activité de la zoxazolamine chez le rat blanc au cours de l'immobilisation forcée accompagnée ou non d'hypothermie" (Zoxazolamine metabolism and activity in white rats during restraint with or without hypothermia). *Arch. Sci. Physiol.* **27**: 37-53 (1973).

J7,077/73

In rats, the muscle-relaxing effect of *zoxazolamine* is considerably enhanced by the stress of restraint, especially in cold surroundings. This is ascribed mainly to increased sensitivity of the nervous system and to a lesser extent to impaired zoxazolamine metabolism during stress.

Lindenbaum, E. S., Diamond, B., Yaryura-Tobías, J. A.: "Nicotinic acid and restraint induced ulcers." *Acta Physiol. Lat.-Amer.* **23**: 288-292 (1973). J9,059/73

In rats, the gastric ulcers produced by restraint coupled with food and water deprivation are more effectively inhibited by *nicotinic acid* than by *chlorpromazine*.

Sibilly, A., Krivošić, I., Foucher, G., Fresnel, P. L., Boutelier, P.: "Prévention locale de l'ulcère gastrique expérimental. (Etude préliminaire)" (Topical prevention of experimental gastric ulcer. [Preliminary study]). *J. Chir. (Paris)* **106**: 521-534 (1973). J10,151/73

In rats, the stress ulcers produced by restraint are aggravated by *fasting* and prevented by oral administration of *glucose* or *aluminum gel*. Neutralization of the gastric acid does not seem to be decisive since aluminum gel protects less than hypertonic glucose; perhaps the latter helps to maintain cell metabolism and the gastric barrier.

Redgate, E. S.: "Neural control of pituitary adrenal activity in *Cyprinus carpio*." *Gen. Comp. Endocrinol.* **22**: 35-41 (1974).

H81,914/74

"The prompt responses of plasma cortisol concentration to stimuli, such as sound, hypothalamic stimulation, the photoperiod, and

restraint, indicate that the pituitary adrenal system of the *carp* is controlled by neural pathways in the brain of this teleost."

Tran, T. A., Gregg, R. V.: "Hypothermia in restraint-induced gastric ulcers in *parabiotic* rats." *Gastroenterology* **67**: 271-275 (1974). J15,225/74

Hadjiolova, I.: "Veränderungen des Plasma- und Nebennierenrindencorticosterone bei Ratten während Hypokinesie und zusätzlicher Stress-Einwirkungen (Influence of hypokinesia and subsequent stress upon the rat plasma and adrenal corticosterone level)." *Int. Arch. Arbeitsmed.* **33**: 59-70 (1974). J17,473/74

Studies on plasma and adrenal corticosterone in rats exposed to different stressors (*heat, restraint, noise*) alone or in combination. "A moderate increase in the levels of both plasma and adrenal corticosterone was observed after 24 hrs of hypokinesia. In a subsequent period of 60 days the corticosterone levels did not differ significantly from the levels found in the control animals. However, a marked decrease in adrenal weight and a slighter response to additional thermal stress were demonstrated after 60 days of hypokinesia. Differences between the restrained and the control animals were also found in the adaptation to chronic auditory stress."

Athletics

For the sake of convenience, we have separated the literature on athletics from that on muscular exercise in general, but from a medical point of view this is justified only in that the two are usually associated with different sets of conditioning factors. For example, the psychologic accompaniments of forced labor and the environmental stimuli of work in factories or mines (noise, vibration, air pollution, extremes of temperature) frequently differ from those of athletic activities, usually performed in healthy surroundings. Yet, here also, hypoxia in mountain climbing, compression and decompression in diving and so on, may add to the stressor effect of muscular work itself.

Perhaps the most important conditioning agents in the stress response during competitive athletic performances are emotional factors. Interestingly, observations on Harvard-Yale boat racing crews showed marked eosinopenia even in the coxswain, who shared only the excitement, not the muscular work, of his teammates.

In athletes, uropepsin excretion is increased during the alarm reaction stage after various types of effort.

In young athletes, swimming to exhaustion may cause renal malfunction with abundant urinary casts and proteinuria.

Of course, most publications on the stressor effect of athletic exercise emphasize its therapeutic action in helping patients keep fit, or in rehabilitation, as after cardiac accidents or damage to the locomotor system.

The most typical stressor actions of athletic exercises are changes in adaptive hormone production. In high school boys, running and other athletic activities increase EP and NEP excretion to approximately the same extent. Many further observations confirm that catecholamine (EP, NEP, VMA) elimination rises after basketball, soccer, skiing, rowing and other types of physical exertion. Allegedly, aggressive emotional displays tend to favor NEP excretion, whereas anxious but passive activities are more likely to augment EP elimination. Aldosterone excretion rose, particularly in certain anxiety states associated with athletics, while glucocorticoid production, as indicated by blood levels, urinary excretion products or eosinopenia, depended more upon the intensity than the type of activity or the emotional attitude toward it.

Bicycle riding tends to decrease plasma insulin levels, while STH, cortisol and EP values rise. However, these observations require confirmation as they have been based on a relatively small number of subjects. Exercise on the bicycle ergometer raised the cortisol level not only in blood and urine but also in saliva; yet, with training, most of the hormonal changes tend to diminish as a consequence of adaptation.

The combination of athletic exercise with various conditioning agents has not yet been adequately studied using reliable indicators of stress. Of course, the effects of "doping," tranquilizers, alcohol, and other psychoactive drugs upon performance are well known, but this is not strictly relevant to the subject of our treatise.

In ski jumpers, emotional stressors are predominantly mediated through adrenergic β -receptors, and accordingly, the associated tachycardia is diminished by β -receptor-blocking agents, for example, oxprenolol.

In rats forced to swim in cold water, the brain NEP stores are greatly diminished but this change can be prevented by rewarming or swimming in warm water. Here, apparently, temperature is an important conditioning factor.

relation to fatigue, within this monograph on stress.

Eliot, R. S.: *Stress and the Heart*, Vol. 1, p. 415. Contemporary Problems of Cardiology. Mount Kisco, N.Y.: Futura, 1974.

E10,556/74

Monograph containing many articles by numerous experts on the role of stress in the production of cardiovascular disease with special reference to hypertension and myocardial infarction. Individual chapters deal with the role of occupation, homeostasis, environmental influences, sex, athletics, emotion, stress tests, and the therapeutic value of various techniques for relaxation, including Transcendental Meditation, Yoga, Zen, sencit cycles, hypnosis, and related practices.

Opie, L. H.: "Sudden death and sport." *Lancet* February 1, 1975, pp. 263-266.

H98,865/75

"Of 21 sudden deaths in sportsmen, 18 were thought to be caused by heart-attacks either during or after sport." Psychologic factors were considered to be important in eight cases.

→**Hormones.** Renold, A. E., Quigley, T. B., Kennard, H. E., Thorn, G. W.: "Reaction of the adrenal cortex to physical and emotional stress in college oarsmen." *N. Engl. J. Med.* **244:** 754-757 (1951). B65,108/51

Harvard-Yale boat race crews showed a marked eosinopenia which was interpreted as a sign of stress-induced corticoid secretion. Muscular effort was not the only stressor, for the coxswain likewise responded with pronounced eosinopenia although he was almost exclusively under emotional stress.

Euler, U. S. von, Hellner, S.: "Excretion of noradrenaline and adrenaline in muscular work." *Acta Physiol. Scand.* **26:** 183-191 (1952). B89,579/52

In male high school students, muscular work (running, general athletics) increased EP and NEP excretion approximately to the same extent. The authors conclude that there appears to be a correlation between the degree of stress involved in work and the output of catecholamines.

Hill, S. R. Jr., Goetz, F. C., Fox, H. M., Murawski, B. J., Krakauer, L. J., Reifenstein, R. W., Gray, S. J., Reddy, W. J., Hedberg, S. E., St. Marc, J. R., Thorn, G. W.: "Studies on adrenocortical and psychological

response to stress in man." *Arch. Intern. Med.* **97:** 269-298 (1956). C35,720/56

The intense muscular and psychogenic stressor effect of crew racing caused eosinopenia with increased urinary elimination of 17-OHCS, 17-KS, and uropepsin, but signs of adrenal hyperactivity were obvious during the prerace tension as well. Earlier studies found that eosinopenia developed likewise in the coxswain and coach during the race; hence "the physical exertion of rowing was not the only stress involved capable of inducing a marked eosinopenia."

Pugh, L. G. C. E.: "The adrenal cortex and winter sports. With a note on other exercise." *Br. Med. J.* February 7, 1959, pp. 342-344. C64,349/59

During winter sports, eosinopenia may become very severe, but it tends to diminish after the third week in association with improved physical conditions. "In Channel swimming virtual disappearance of the eosinophils and an eightfold rise in urinary 17-hydroxysteroids, reported elsewhere, suggest an adrenal cortical response comparable with that found in major surgery."

Elmadjian, F.: "Epinephrine, norepinephrine, and aldosterone: release and excretion." In: Schaefer, K. E. (ed.), *Man's Dependence on the Earthly Atmosphere*, pp. 100-116. New York: Macmillan, 1962. D30,946/62

Studies of EP and NEP secretion in normal people and psychiatric patients during stressful life situations "support the hypothesis that active, aggressive, emotional displays are related to increased excretion of norepinephrine, whereas tense, anxious, but passive emotional displays are related to increased excretion of epinephrine." Aldosterone elimination was elevated during certain anxiety states without demonstrable increases in catecholamine excretion. The stressors examined were manipulation of the Hoagland-Werthessen pursuit meter, hockey, boxing, basketball, baseball and anxiety-inducing interviews.

Schmid, E., Schmerwitz, K.: "Untersuchungen über die Aktivierung des sympathikoadrenalen Systems bei Basketballspielern an Hand der Vanillinmandelsäure-Bestimmung im Harn" (Studies on the activation of the sympathetic adrenal system in basketball players, as shown by urinary vanillylmandelic acid excretion). *Sportarzt und Sportmed.* No. 12: 399-402 (1964). G26,892/64

In basketball players, urinary VMA excretion rises in proportion to the effort exerted (30 refs.).

Simpson, H. W.: "Field studies of human stress in polar regions." *Br. Med. J.* March 4, 1967, pp. 530-533. F78,155/67

In men at a British Antarctic sledging base, eosinopenia was especially marked in the evening after a full day of travel. Similarly, in a party skiing 400 miles across Greenland, 17-OHCS excretion was high during the forty days of crossing from coast to coast. No adaptation to stress occurred.

Nowacki, P., Schmid, E.: "Über die sympathico-adrenale Reaktion im Training und Wettkampf bei verschiedenen Sportarten" (Sympathetic adrenal activation by various athletic activities during training and competition). *Med. Welt* 21: 1682-1688 (1970).

H30,897/70

Comparative study on the increase in plasma and urinary catecholamines elicited by different athletic activities such as basketball, skiing, handball and rowing. There is good evidence that what counts in such activities is not only the muscular but also the psychic stressor component.

Rose, L. I., Friedman, H. S., Beering, S. C., Cooper, K. H.: "Plasma cortisol changes following a mile run in conditioned subjects." *J. Clin. Endocrinol. Metab.* 31: 339-341 (1970).

Viru, A., Körge, P.: "Metabolic processes and adrenocortical activity during marathon races." *Int. Z. Angew. Physiol.* 29: 173-183 (1971).

G84,664/71

Among fourteen first-class marathon runners, all except the two best showed lowering of blood cortisol levels during the race. Urinary sodium decreased and potassium increased. In most cases, glutamic-pyruvic transaminase activity and nonprotein nitrogen rose in plasma, and excretion of nitrogen and creatinine was reduced. "It was suggested that before the end of the marathon race the protein catabolism is diminished due to a decrease of the glucocorticoid function of the adrenal gland."

Neuropsychologic Stimuli

(See also Physical Agents—sound, vibration, electroshock; Occupations—aerospace, military; Treatment—Transcendental Meditation, Zen, Yoga, hypnosis, psychoanalysis; Mechanisms—selective stimulation or lesion of certain nervous centers; Stress Tests—media, inter-

views; and various other sections of this treatise where agents which affect the nervous system are discussed)

Those neuropsychologic stressors which have one predominant characteristic (pain, anxiety, public speaking, fighting, sensory or sleep deprivation, motivation, cognition, and so on) are discussed in separate sections to facilitate retrieval of data on particular subjects. However, the various manifestations of psychogenic stress are arbitrarily discussed conjointly in the section, Anxiety, Anticipation, Fear, Arousal (p. 203), since all nervous stimuli in this category overlap. Here, we shall also find key references on combined treatment with neuropsychologic stressors and other agents.

Generalities

Neuropsychologic stimuli are of paramount importance, especially in higher mammals because of their complex CNS. This is particularly true of man, for whom cognitive and emotional stimuli play a predominant rôle in his interpersonal relationships within his family, workplace, social life and in the manifold activities necessary for preserving harmonious homeostasis among individuals, groups and nations. Furthermore, with increasing phylogenetic development, CNS regulation has assumed greater importance, controlling biochemical defenses, even against physical aggressors, both directly (for example, through logical analysis of responses and autonomic nervous reactions) and indirectly (for example, through the hypothalamic centers directing the defensive activities of the endocrine system). It is for this reason that laymen, and even some physicians, are still tempted to equate stress, and, particularly distress, with nonspecific arousal, mental exhaustion or frustration. Such a restriction of the concept is perfectly satisfactory for the great majority of stress situations encountered by man in his daily life. However, this would greatly limit the scope of the stress concept by excluding from it the nonspecific defenses that persist after decerebration or during deep anesthesia, when conscious feelings of arousal or frustration are eliminated, as well as the nonspecific stress reactions of all comparatively primitive living beings, such as plants and unicellular organisms, that have no nervous system.

A general overview of this subject can be obtained by consulting some of the many books and review articles on neuropsychiatric agents that will be cited. More specific information on individual stimuli, especially those important for man, will be considered in separate sections. However, at the outset, attention must be called to the difficulty of categorizing neuropsychologic stimuli, because as we have said, they almost always overlap, owing to the many connections between the parts of the nervous system, which tend to generalize the impulses wherever they happen to arise. If this is kept in mind, some categorization will still be of practical use in leading the reader rapidly to information specifically concerned with pain, anxiety, arousal, fight, leisure, sensory deprivation, sleep deprivation, motivation, cognition, or whatever. Depending upon the degree of his interest, he may then also look up other more or less closely related subjects but will have immediate access to what we have considered the most instructive key references dealing with one of these stimuli in particular.

Pain and Grief

(See also Climate, Environment—social, cultural, isolation, captivity, concentration camps, relocation, catastrophe; and various other agents which can cause pain)

It will be recalled that pain, hunger, fear and rage were the stimuli that Cannon used in his classic studies on emotional factors capable of stimulating sympathetic activity and EP secretion. Ever since then, somatic pain and mental pain (grief) have been the subject of intensive investigations, not only with regard to this special response but as paradigms of stressors of considerable importance, particularly in man and other higher mammals.

A number of more or less accurate dolorimeters have been devised to produce a standard degree of pain (by heat, electric stimulation and so on), as a basis for objective measurements of its mental and somatic consequences. Undoubtedly these represent an important step toward quantification, but unfortunately they are still subject to many imperfections, because the same degree of stimulation may cause different intensities of pain depending upon a variety of conditioning factors which determine somatic pain sensitivity. Furthermore, such instruments do not help in the quantitative assessment of the indices that can be considered as truly nonspecific and hence as stress effects. All these criticisms apply even more to mental pain, such as grief and sorrow.

Still, it has been clearly established that physical pain increases plasma cortisol levels and interferes with its normal circadian rhythm. Even psychoneurotics respond to standardized heat (applied to the forehead) with lymphopenia, increased GSR, and EEG changes characteristic of stress; hence, such tests are appropriate even for mentally deranged patients.

In rabbits, painful electroshock applied to the earlobes causes an increase in plasma corticoid and FFA levels as well as polymorphonuclear leukocytosis. The literature contains a distressingly large number of reports on both physical and mental torture, sometimes using the most ingenious techniques of cruelty.

Somewhat unexpectedly, in mice, painful stimuli accelerated morphine-induced analgesia, but photic and auditory stimuli did not.

The sorrow of parents whose children suffered from neoplastic disease led to an increase in 17-OHCS excretion, which depended largely upon the individual's coping

behavior. As might have been expected, the response was greatest when the parents were first informed of the bad prognosis; later, adaptation progressed at varying rates but rarely became complete. Similarly, a study on army recruits who had recently lost a parent, revealed increases in 17-OHCS excretion that roughly paralleled the psychologic manifestations of their grief. In mothers of spina bifida children, responses to the MPI questionnaire were thought to be fairly accurate criteria of their subjective grief.

A multivariate analysis of stress effects (GSR, respiration rate, muscle tension, heart rate, digit span, tracking performance, and so on) showed that it is possible to discriminate patterns of response to pain from those elicited by other stressors. This was considered to be surprising "in that theories of response to aversive stimuli such as Cannon's and Selye's predict essentially similar response patterns to any strong emotion whether pain, fear, or threat." Such misunderstandings of the stress theory are so common that they deserve careful consideration. An investigation on stress can be meaningful only if it is realized that stress is the nonspecific response of the body to any demand, and hence by definition must be uniform whatever the eliciting agent. However, its manifestations cannot be the same in all cases because of the diverse conditioning agents which always influence it. As explained in the General Outline of the stress theory (in the introductory section of this treatise), the most important among these are the specific effects of the particular stressor employed, as well as the numerous endogenous and exogenous conditioning factors which invariably modify the standard response to stress. In the last-mentioned series of investigations, the most striking fact was that so many parameters of the multivariate analysis were similarly affected. It would, however, be inconceivable for them always to have been precisely the same in all respects, regardless of the particular stressor used and of individual variations in responsiveness.

Pain and Grief

(See also our earlier stress monographs, p. xiii)

Lindemann, E.: "Symptomatology and management of acute grief." *Am. J. Psychiatry* **101**: 141-148 (1944). B26,743/44

Malmo, R. B., Shagass, C., Davis, J. F., Cleghorn, R. A., Graham, B. F., Goodman, A. J.: "Standardized pain stimulation as controlled stress in physiological studies of psychoneurosis." *Science* **108**: 509-511 (1948). B47,043/48

In psychoneurotics, heat applied to the forehead caused stress manifested by lymphopenia, as well as GSR and EEG changes. It is concluded that pain tests "may profitably be employed in more extensive analyses of disturbances in mental patients undergoing stress."

Cannon, W. B.: *Bodily Changes in Pain, Hunger, Fear and Rage*, p. 404. Boston: Charles T Branford, 1953. A19,828/53

Excellent summary of the author's classic observations on the somatic manifestations of acute emotions, particularly with regard to the effect of fear, rage, hunger and thirst upon the sympathetic nervous system and EP secretion.

Grad, B., Kral, V. A.: "Adrenal cortical stress effects in senility. II. The response to heat stimulation produced by the Hardy-Wolff-Goodell dolorimeter." *Can. Psychiatr. Assoc. J.* **6**: 66-74 (1961). J10,361/61

Friedman, S. B., Mason, J. W., Hamburg, D. A.: "Urinary 17-hydroxycorticosteroid levels in parents of children with neoplastic disease. A study of chronic psychological stress." *Psychosom. Med.* **25**: 364-376 (1963). E23,527/63

Parents of children who suffered from neoplastic diseases were tested for 17-OHCS excretion and ranked according to its intensity. "Adrenal cortical activity was hypothesized to be related to the effectiveness of the individual's coping behavior. The group data

showed slight, but statistically significant, elevations at the time the parents were first admitted to the ward and when psychological stress was judged to be maximal."

Shenkin, H. A.: "The effect of pain on the diurnal pattern of plasma corticoid levels." *Neurology* (Minneap.) **14**: 1112-1117 (1964). C23,146/64

In patients with pain of somatic origin, plasma cortisol levels were usually increased, whereas in subjects without objective evidence of the cause of pain, these values and their diurnal variations were frequently normal.

Chodoff, P., Friedman, S. B., Hamburg, D. A.: "Stress, defenses and coping behavior: observations in parents of children with malignant disease." *Am. J. Psychiatr.* **120**: 743-749 (1964). G9,191/64

Data on the stressor effect of grief upon parents of children with leukemia.

Winnik, H. Z.: "Second thoughts about 'psychic trauma'?" *Isr. Ann. Psychiatry* **7**: 82-95 (1969). J23,437/69

Discussion of the relationship between psychic trauma and the G.A.S.

Poe, R. O., Rose, R. M., Mason, J. W.: "Multiple determinants of 17-hydroxycorticosteroid excretion in recruits during basic training." *Psychosom. Med.* **32**: 369-378 (1970). G77,861/70

In recruits during basic training, psychologic ratings and weight were correlated with, and together predicted, 17-OHCS levels more accurately than did either alone. In twelve of fourteen men who lost a parent, the 17-OHCS values were extremely high. The results "suggested that an individual's 17-OHCS level is influenced by psychologic, biologic, historic and environmental variables" (27 refs.).

Kakizaki, T.: "Stress response during mental task. 1. Biochemical response of rabbits subjected to an electrical stimulation." *Ind. Health* **9**: 99-104 (1971). J10,262/71

Stress was produced in rabbits by painful electric stimulation of the ear lobes. Among the many possible indicators, the serum 11-OHCS and FFA levels were consistently increased and blood leukocytes decreased. Blood

lactic acid, serum phospholipids, and LDH activity were less significantly elevated.

Hare, E. H., Payne, H., Laurence, K. M., Rawnsley, K.: "Effect of severe stress on the Maudsley personality inventory score in normal subjects." *Br. J. Soc. Clin. Psychol.* **11**: 353-358 (1972). G97,218/72

In mothers of spina bifida children, the MPI score is considerably influenced by the stress of grief.

Hofer, M. A., Wolff, C. T., Friedman, S. B., Mason, J. W.: "A psychoendocrine study of bereavement. Part I. 17-Hydroxycorticosteroid excretion rates of parents following death of their children from leukemia." *Psychosom. Med.* **34**: 481-491 (1972). G97,602/72

Hofer, M. A., Wolff, C. T., Friedman, S. B., Mason, J. W.: "A psychoendocrine study of bereavement. Part II. Observations on the process of mourning in relation to adrenocortical function." *Psychosom. Med.* **34**: 492-504 (1972). G97,603/72

Urinary 17-OHCS excretion rates in parents of children who died of leukemia show rather variable results from which few conclusions can be drawn.

"Medical aspects of torture." *Lancet* October 20, 1973, pp. 900-901. H77,363/73

Brief report of a group that met in London under the auspices of Amnesty International to study the medical aspects of physical and mental torture methods which cause severe stress. A short list of pertinent publications is attached.

Stevens, M. W., Domer, F. R.: "Alterations in morphine-induced analgesia in mice

exposed to pain, light or sound." *Arch. Int. Pharmacodyn. Ther.* **206**: 66-75 (1973).

H82,603/73

In mice, pain stimuli significantly increased both the onset and intensity of morphine analgesia. This was not the case in animals exposed to photic or auditory stimuli.

Davidson, P. O., Neufeld, R. W. J.: "Response to pain and stress: a multivariate analysis." *J. Psychosom. Res.* **18**: 25-32 (1974).
J12,477/74

In man, "it is possible, using multiple measures and appropriate statistical analyses, to discriminate patterns of response to pain

from other types of stressors. These results are encouraging and somewhat surprising in that theories of response to aversive stimuli such as Cannon's and Selye's predict essentially similar response patterns to any strong emotion, whether pain, fear, or threat." The measures used were GSR, respiration rate, muscle tension, heart rate, anxiety differential, digit span, tracking performance and so on (47 refs.). [Many of these parameters were similarly affected, but differences were to be expected because the specific actions of each stressor influence the stereotyped pattern through conditioning (H.S.).]

Anxiety, Anticipation, Fear, Arousal

(See also Climate and Environment—captivity, concentration camps, relocation, catastrophe; Occupations—aerospace, military, industry; Manic-depressive illness—suicide; and various other sections of this treatise in which agents that cause anxiety, anticipation, arousal or fear are discussed)

As we said at the outset of this chapter, neuropsychologic stressors that have one predominant characteristic (pain, anxiety, fighting, sensory or sleep deprivation, motivation, cognition, and so on) are treated in separate sections to facilitate retrieval of data on particular subjects. However, the various manifestations of psychogenic stress are arbitrarily discussed conjointly in this section on anxiety, anticipation, fear and arousal, since all these nervous stimuli overlap. Here, we shall also find key references on the combined effect of neuropsychologic stressors and other agents, except those used for therapy. (For these see Treatment.)

Most of the experimental work on the stressor effect of anxiety, anticipation, fear and arousal was concerned with reactions to such experiences as problem solving, academic examinations, anticipation of surgery, social problems and real or simulated panic situations. In the majority of these investigations, only psychologic indicators of stress were employed, and with these it is always difficult if not impossible to ascertain that they really reflect nonspecific biologic stress as presently defined.

Still—as was expected—these studies made it clear that anxiety does cause distress and interferes with performance in various tests. For example, students who were praised (irrespective of their actual success) after a first examination usually did better during a second test than those who were sharply criticized. But even here conditioning factors play a decisive role, as shown by personality inventories which can predict coping behavior to a considerable extent. Some people are stimulated by failure to ever greater efforts, while others are discouraged.

The term *arousal* is used rather loosely and is difficult to define. Certainly, it applies to any state of vigilance, but also to fighting, aggression, hate and anxiety; hence, it is somewhat arbitrary whether a particular psychologic stress situation is mentioned in one or the other of these categories. For example, the stressor effect of

Public Speaking has been listed separately after Anxiety, to facilitate retrieval. In any event, arousal is not synonymous with stress, but every type of arousal can produce typical stress manifestations.

A study of the general literature discussed in this section is more likely to help by offering practical tips on coping with anxiety than by elucidating stress mechanisms.

We may facilitate orientation in this somewhat complicated chapter by enumerating the subheadings that refer to separate sections on the effects of anxiety, anticipation, fear and arousal.

- Generalities
- Catecholamines
- ACTH and Corticoids
- STH
- TTH and Thyroid Hormones
- Other Hormones and Hormone-like Substances
- Metabolites
- Morphology
- Nervous System (including performance in general)
- Accident Proneness
- Suicide
- Cardiovascular System
- Varia
- +Genetics
- +Restraint
- +Electroshock
- +Drugs, Hormones
- +Varia

→**Hormones.** The most objective and quantifiable indicators of stress elicited by anxiety, anticipation, fear and arousal are hormonal changes. Most of the early studies were concerned with the increase in *glucocorticoid* production. This was virtually uniformly confirmed, in both man and experimental animals as for example, in patients anticipating surgery, in students undergoing academic examinations, in psychiatric patients in whom anxiety occurred spontaneously or was evoked by discussion of stressful subjects, in hypnotically-induced anxiety, in experimental situations causing feelings of shame or threat.

Increased urinary 17-OHCS excretion and elevated blood cortisol levels were observed repeatedly in patients who attempted, and sometimes subsequently committed, suicide. Also, the highest cholesterol concentrations were found in the adrenals of patients who committed suicide or died of hypertensive disease.

Even the anxiety caused by blood drawing, in subjects unfamiliar with this procedure, may raise blood corticoid levels. This is of special importance in studies in which the first sample is taken for control purposes.

Cortisol given intravenously disappears from the plasma more rapidly in anxious than in normal subjects, despite greater corticoid excretion. This would suggest that corticoid metabolism is accelerated during anxiety-induced fear.

In most of these studies, the increased glucocorticoid production correlated fairly well with psychologic indicators of emotional excitation, and as always depended upon personality factors and other conditioning agents.

In rhesus monkeys, conditioned anxiety and avoidance similarly induced marked elevations of plasma 17-OHCS, quite comparable in magnitude to those elicited by a maximally effective dose of intravenous ACTH. Monkeys brought to an experimental cage for the first time also exhibited a substantial rise in plasma corticoids; this is why the first sample should not be used to determine the normal control value. Relocation to a new cage is a well-known, commonly used stressor in various animal species.

Much less is known about *mineralocorticoid* production during fear and anxiety. In healthy people undergoing stressful experiences, such as examinations or the presentation of papers at public meetings, aldosterone excretion was frequently elevated. This rise roughly paralleled the degree of anxiety and was associated with an increase in 17-OHCS elimination.

The *ACTH* blood levels are likewise greatly elevated in students during oral examinations, as well as in preoperative patients. Although few publications deal with this fact, it is of course indirectly implied by the amply documented rise in glucocorticoid production.

Probably the earliest experiment on increased *catecholamine* production during fear was a demonstration by Cannon (1911) that "cats frightened by the proximity of a barking dog showed indirect evidence of enhanced adrenal secretion" which indicated EP release from the adrenal medulla, since at that time NEP and the importance of its discharge from sympathetic nerve endings were not yet known.

Many more recent investigators examined the same problem with modern techniques and found that during oral examinations increased glucocorticoid elimination is associated with a rise in the urinary excretion of both EP and NEP. Allegedly, in various stressful life situations, including anxiety-inducing interviews, active aggressive emotional displays are associated with a rise in NEP excretion, whereas tense, anxious, but passive behavior results in a predominant elevation of EP elimination. In students, feelings of anticipation, uncertainty and helplessness raised EP output three-fold and NEP secretion to a somewhat lesser extent in comparison with values in controls reading magazines while comfortably relaxing. In another study in which students were asked to accomplish choice-reaction tasks and received electric shocks as punishment for poor performance, both EP and NEP excretion rose. By increasing the subject's control over the situation, it was possible to counteract the rise in EP but not in NEP, in comparison with controls who received the punishment at random, irrespective of performance. In general, subjects with the highest rates of EP and NEP excretion were most efficient in their performance.

In rhesus monkeys, conditioned emotional disturbances augment NEP concentrations in plasma, roughly in proportion to the rise in plasma 17-OHCS.

The increased secretion of catecholamines during anxiety may lead to a cycle since it has also been demonstrated that in man continuous intravenous infusions of EP in turn produce moderate anxiety reactions (in addition to the classic stress effects of sweating, tachycardia, hypertension and cutaneous pallor).

Little is known about other hormonal responses to anxiety, but in wild rabbits fear can cause an acute discharge of *TTH*, often associated with an actual inhibition of ACTH secretion. The resulting, sometimes fatal, stress thyrotoxicosis may have a parallel in clinical medicine, and the fact that here increased TTH production is accompanied by diminished ACTH secretion would appear to support the "hypophyseal shift" theory. As expected, hypophysectomy prevents the fear-induced TTH discharge in these rabbits.

In students, the stress of an examination significantly raised 17-KGS and slightly increased 17-KS excretion. It remains to be seen whether this indicates a rise in testoid or corticoid hormones.

In man, anxiety-inducing emotional stress (like the injection of pyrogen) increases plasma STH levels. A similar rise in plasma STH (concurrently with an elevation of plasma cortisol) was seen in anxious but not in relaxed patients undergoing cardiac catheterization.

In rhesus monkeys, conditioned avoidance raises plasma STH levels.

→**Metabolites.** Among other biochemical changes elicited by anxiety in man, emotional *hyperglycemia* and even temporary *glycosuria* were the first to be observed. In rats, psychogenic stress increases blood sugar, as well as *insulin hypoglycemia*.

More recently, special attention has been given to alterations in *lipid* metabolism. For example, in students undergoing examinations, the blood cholesterol content may rise very significantly, often in combination with an increase in plasma lipoproteins of low density. These and other anxiety-inducing experiences, such as stressful interviews, criticism and frustration, have been shown to augment plasma *triglycerides* and *FFA*. Comparable findings have been made in animals.

In patients showing obvious severe anxiety before surgery, the blood *pyruvic acid* level rises and *hippuric acid* synthesis decreases.

Blood *uric acid* remained approximately unchanged in medical students who, during examinations, exhibited a marked rise in blood *cholesterol*.

The augmented corticoid secretion during academic examinations may or may not be associated with changes in *diuresis* and *creatinine* excretion. In dogs, emotional excitement inhibits diuresis, presumably as a consequence of enhanced vasopressin secretion. On the other hand, in patients, the discussion of stressful subjects raised diuresis and increased 17-OHCS, *nitrogen*, *sodium* and *potassium* elimination.

The effects of emotional stress upon *blood clotting* mechanisms differ in normotensive and hypertensive individuals. There is general agreement that emotional stress raises plasma FFA, often with a concurrent increase in blood pressure and corticoid secretion.

→**Morphology.** One of the most striking morphologic manifestations of stress induced by fear was the great increase in the incidence of often perforating *stress ulcers* during air raids in London.

In students, before and throughout examinations, *eosinopenia* was quite consistently observed. This effect of anxious anticipation also occurred (in combination with other typical manifestations of stress) in the coxswain and coach during crew racing. Eosinopenia could even be elicited in subjects induced to believe that they accidentally caused injury to a companion through misuse of explosives. In rats, anticipation of an electroshock produces the same effect.

In hares kept in captivity, the constant presence of a hunting dog causes *testicular* atrophy, and in rats exposed to fear by keeping them in front of a dog's cage, the histologic and biochemical changes of *thyrotoxicosis* were associated with a decrease in serum cholesterol and body weight. Apparently, the genetic factors that condition thyroid reactions to stress also influence thyroid-mediated alterations in serum cholesterol.

→**Nervous System.** Of course, the greatest attention was given to the *psychologic* consequences of anxiety and fear, such as the impairment of the most diverse types of problem solving and performance, learning ability, coping behavior, accident and suicide proneness and so on. In these studies, the techniques used for inducing fear or anxiety, anticipation of pleasant or unpleasant events, and the criteria for the determination of psychologic reactions, were so different and complex that the pertinent literature does not lend itself to meaningful condensation and must be consulted in the abstracts of the original publications.

The effects of various psychogenic stressors upon problem solving and perception vary according to conditioning factors. Psychologic stress appears to result in a special intolerance of ambiguity and incongruity in the expected performance.

A very common and characteristic manifestation of stress induced by anxiety is the rise in the GSR with increased *sweating*.

Anxiety, like so many other psychogenic stressors, produced *cardiovascular* changes such as an increase in blood pressure and pulse rate associated with flushing or pallor of the skin, and rather characteristic ECG alterations.

→**Varia.** One of the most dramatic effects of acute anxiety is the so-called *Voodoo death* induced by spells, sorcery or "black magic" among primitive natives in various parts of the world. Although its mechanism has never been clearly established, it may be caused by sudden arrhythmias or ventricular fibrillation.

+**Varia.** (see also Treatment) *Genetic* predisposition certainly plays a very important role in determining stress resistance. Certain strains of wild rabbits can be literally frightened to death. These fear responses are associated with thyroid hypertrophy, increased TTH production and a diminution of ACTH secretion, which contrasts sharply with the rise in ACTH production characteristic of stress in other strains. In students undergoing academic examinations, augmentation of plasma cortisol is also largely dependent upon constitutional factors.

Nitrous oxide, in amounts just sufficient to cause euphoria, impairs problem-solving activity, as does exposure to various stressors, but combining nitrous oxide and stress allegedly results in a cancellation of this blocking effect.

In rats, mouse-killing activity is blocked by chronic electroconvulsive shocks or *antidepressant drugs*.

In rats, conditioned anxiety and unpredictable electric shocks aggravated the production of stress ulcers by *restraint*; subdiaphragmatic vagotomy did not significantly reduce their incidence.

In *schizophrenic* patients, convulsive and nonconvulsive electrostimulation produced marked eosinopenia.

In persons with *vestibular defects* who accompanied experienced pilots on acrobatic flights, the usual increase in urinary catecholamine and corticoid excretion was largely suppressed, presumably because their inner ear anomalies prevented them from fully experiencing the stressor effects of the flights.

Mason, J. W., Mangan, G. Jr., Brady, J. V., Conrad, D., Rioch, D. M.: "Concurrent plasma epinephrine, norepinephrine and 17-hydroxycorticosteroid levels during conditioned emotional disturbances in monkeys." *Psychosom. Med.* **23**: 344-353 (1961).

D10,040/61

In rhesus monkeys, various conditioned emotional disturbances augment 17-OHCS and NEP concentrations in plasma. "It is suggested that the element of uncertainty or unpredictability, in combination with such factors as the threat of a noxious stimulus and the anticipation of coping activity, may

be a particularly critical factor in the determination of epinephrine release during emotional disturbances."

Pekkarinen, A., Castrén, O., Iisalo, E., Koivusalo, M., Laihinens, A., Simola, P. E., Thomasson, B.: "The emotional effect of matriculation examinations on the excretion of adrenaline, noradrenaline, 17-hydroxycorticosteroids into the urine and the content of 17-hydroxycorticosteroids in the plasma." In: *Biochemistry, Pharmacology and Physiology*, pp. 117-137. London: Pergamon Press, 1961.

E85,207/61

"While an operation often clearly increases both the excretion of adrenaline and noradrenaline and total 17-OHCS in the plasma, the psychic tension of student examination clearly increases the excretion of adrenaline only. The eosinopenia caused by examination therefore seems to be chiefly due to the increased excretion of adrenaline." The free 17-OHCS in plasma immediately after examination and urinary elimination of these compounds before and during the tests are less consistently increased, and the conjugated 17-OHCS levels remain normal.

Elmadjian, F.: "Epinephrine, norepinephrine, and aldosterone: release and excretion." In: Schaefer, K. E., *Man's Dependence on the Earthly Atmosphere*, pp. 100-116. New York: Macmillan, 1962.

D30,946/62

Studies on EP and NEP secretion during stressful life situations in normal people and psychiatric patients "support the hypothesis that active, aggressive, emotional displays are related to increased excretion of norepinephrine, whereas tense, anxious, but passive emotional displays are related to increased excretion of epinephrine." Aldosterone elimination was elevated in certain anxiety states without demonstrable increases in catecholamine excretion. The stressors examined were manipulation of the Hoagland-Werthessen pursuit meter, hockey, boxing, basketball, baseball and anxiety-inducing interviews.

Levi, L.: "The urinary output of adrenalin and noradrenalin during experimentally induced emotional stress in clinically different groups. A preliminary report." *Acta Psychother.* **11**: 218-227 (1963).

E37,966/63

Healthy young soldiers were exposed to "industrial stress" simulating actual working conditions in a factory or workshop, or to "film stress" (viewing scenes of cruelty, vio-

lence and military surgery). Both stressors caused increased catecholamine excretion.

Euler, U. S. von: "Quantitation of stress by catecholamine analysis." *Clin. Pharmacol. Ther.* **5**: 398-404 (1964). G18,238/64

Review of the literature and personal observations on man suggest that "gravitational stress and exposure to cold are mainly associated with an increase in the norepinephrine excretion, indicating the importance of this hormone in circulatory and temperature controlling homeostatic mechanisms. Mental stress involving exhilarating or aggressive reactions is also associated with an increase in the norepinephrine excretion. The types of emotional stress which are mainly characterized by apprehension, anxiety, pain, or general discomfort are regularly accompanied by an increase in the epinephrine excretion." Special sections are devoted to catecholamine excretion associated with flying, mental work and exposure to cold.

Pátkai, P., Frankenhaeuser, M., Rissler, A., Bjorkvall, C.: "Catecholamine excretion, performance, and subjective stress." *Scand. J. Psychol.* **8**: 113-122 (1967). G75,474/67

In students undergoing moderately stressful psychologic tests, performance was better among subjects with high than among those with low EP excretion. No consistent relationship could be demonstrated between NEP elimination and psychologic variables.

Pinter, E. J., Peterfy, G., Cleghorn, J. M., Pattee, C. J.: "The influence of emotional stress on fat mobilization; the role of endogenous catecholamines and the β adrenergic receptors." *Am. J. Med. Sci.* **254**: 634-651 (1967). G52,170/67

Anxiety-inducing hypnotic suggestion increases catecholamine secretion and blood FFA. Pretreatment with β -adrenergic blocking agents inhibits the adipokinetic response.

Carlson, L. A., Levi, L., Orö, L.: "Plasma lipids and urinary excretion of catecholamines in man during experimentally induced emotional stress, and their modification by nicotinic acid." *J. Clin. Invest.* **47**: 1795-1805 (1968). H1,440/68

In male volunteers, emotional stressors (dazzling light, standardized criticism, sorting steel balls of different sizes) caused a rise in plasma FFA and triglycerides as well as increased catecholamine excretion. Concurrent treatment with nicotinic acid prevented the elevation in FAA and triglycerides, but not the stressor-induced increase in catechol-

amine elimination or the associated rise in heart rate and blood pressure.

Starlinger, H., Hawel, W., Rutenfranz, J.: "Untersuchungen zur Frage der Catecholaminausscheidung im Harn als Kriterium für emotionalen Stress unter verschiedenen Umgebungsbedingungen. Vibrationsbelastung, Filmdarbietungen und Prüfungssituation" (Studies on the question of urinary catecholamine excretion as a criterion of emotional stress under various environmental conditions. Vibration load, presentation of motion pictures and examination periods). *Int. Z. Angew. Physiol.* **27**: 1-14 (1969).

G65,048/69

Frankenhaeuser, M., Rissler, A.: "Catecholamine output during relaxation and anticipation." *Percept. Mot. Skills* **30**: 745-746 (1970).

G82,215/70

Mere anticipation, uncertainty and a feeling of helplessness evoked heightened catecholamine excretion in students who, while completely inactive, knew that they would occasionally receive relatively mild electric shocks. In comparison with a control group of students reading magazines while comfortably relaxing, those anticipating the harmless shocks had an increased excretion of EP and, to a lesser extent, of NEP. Thus, anticipation of unpleasant though harmless events which the subject cannot influence brings about a nearly threefold increase in EP output.

Frankenhaeuser, M., Rissler, A.: "Effects of punishment on catecholamine release and efficiency of performance." *Psychopharmacologia* **17**: 378-390 (1970). G77,863/70

Male university students were asked to accomplish a choice-reaction task and received electric shocks either at random or as punishment for slow performance. Others were not punished, irrespective of performance. "Punishment produced a rise in both adrenaline and noradrenaline release. By increasing the subject's control over the situation it was possible to counteract the adrenaline increase, while noradrenaline release appeared unaffected. On the whole, subjects with high as compared with low rates of adrenaline and noradrenaline excretion were more efficient in terms of both speed and accuracy of performance."

Webster, A. W.: "Beta-adrenergic stimulants and 'exam nerves.'" *Lancet* September 9, 1972, p. 542.

J20,194/72

Johansson, G., Frankenhaeuser, M., Magnusson, D.: "Catecholamine output in school

children as related to performance and adjustment." *Scand. J. Psychol.* **14**: 20-28 (1973). H80,791/73

In school boys, mean EP excretion increased significantly during performance of an arithmetic test as compared to viewing a neutral film. Among children of both sexes, those with enhanced EP output were better than the others at solving arithmetic problems.

O'Hanlon, J. F., Horvath, S. M.: "Interrelationships among performance, circulating concentrations of adrenaline, noradrenaline, glucose, and the free fatty acids in men performing a monitoring task." *Psychophysiology* **10**: 251-259 (1973). J3,116/73

In young men performing an exacting vigilance test, basal blood EP and NEP were inversely related to glucose. EP initially increased during the test but later returned to its basal level in proportion to performance. NEP was not related to performance. Glucose and FAA were elevated during the task and throughout a control period (watching slide projections).

→**ACTH and Corticoids.** Mirsky, I. A., Miller, R., Stein, M.: "Relation of adrenocortical activity and adaptive behavior." *Psychosom. Med.* **15**: 574-584 (1953) (54 refs.). B89,518/53

Franksson, C., Gemzell, C. A.: "Adrenocortical activity in the preoperative period." *J. Clin. Endocrinol. Metab.* **15**: 1069-1072 (1955). D95,673/55

A great majority of patients examined showed an increase in plasma 17-OHCS during the preoperative period, presumably owing to the stress of anxiety.

Hetzell, B. S., Schottstaedt, W. W., Grace, W. J., Wolff, H. G.: "Changes in urinary 17-hydroxycorticosteroid excretion during stressful life experiences in man." *J. Clin. Endocrinol. Metab.* **15**: 1057-1068 (1955). C8,424/55

In patients, a one-hour discussion of "stressful subjects" caused diuresis with increased 17-OHCS, nitrogen, sodium and potassium excretion.

Bliss, E. L., Migeon, C. J., Branch, C. H. H., Samuels, L. T.: "Reaction of the adrenal cortex to emotional stress." *Psychosom. Med.* **18**: 56-76 (1956). C13,032/56

In normal people and psychiatric patients, emotional stress (subjectively estimated by manifestations of anxiety and tension)

whether occurring spontaneously or elicited experimentally, caused consistent but very modest increases in blood and urinary 17-OHCS. These changes were always much less pronounced than those produced by ACTH, Piromen, insulin, electroshock or moderate physical exercise.

Venning, E. H., Dyrenfurth, I.: "Effect of stress upon excretion of aldosterone." *J. Clin. Endocrinol. Metab.* **16**: 961 (1956).

C14,919/56

In healthy individuals urinary aldosterone excretion was frequently raised during "stressful experiences such as examinations or the presentation of papers at meetings."

Schwartz, T. B., Shields, D. R.: "Urinary excretion of formaldehydogenic steroids and creatinine. A reflection of emotional tension." *Psychosom. Med.* **18**: 159-172 (1956).

C25,345/56

In students undergoing stressful final examinations, increased urinary corticoid excretion occurs fairly regularly but urinary volume and creatinine elimination are not clearly related to the stressor.

Mason, J. W., Brady, J. V., Sidman, M.: "Plasma 17-hydroxycorticosteroid levels and conditioned behavior in the rhesus monkey." *Endocrinology* **60**: 741-752 (1957).

C35,278/57

In rhesus monkeys, conditioned anxiety and avoidance caused marked elevations of plasma 17-OHCS comparable to those elicited by intravenous ACTH in maximally effective doses. The animals also showed a substantial rise in plasma corticoids the first time they were brought to the experimental cage, but not on subsequent occasions.

Venning, E. H., Dyrenfurth, I., Beck, J. C.: "Effect of anxiety upon aldosterone excretion in man." *J. Clin. Endocrinol. Metab.* **17**: 1005-1008 (1957).

C38,804/57

In students sitting for oral examinations, the degree of anxiety was approximately graded in terms of an arbitrary scale. The rise in aldosterone excretion roughly paralleled the extent of anxiety, and was associated with enhanced 17-OHCS elimination.

Mason, J. W., Harwood, C. T., Rosenthal, N. R.: "Influence of some environmental factors on plasma and urinary 17-hydroxycorticosteroid levels in the rhesus monkey." *Am. J. Physiol.* **190**: 429-433 (1957).

C42,224/57

Persky, H.: "Adrenocortical function in anxious human subjects: the disappearance of hydrocortisone from plasma and its metabolic fate." *J. Clin. Endocrinol. Metab.* **17**: 760-765 (1957). J11,139/57

Intravenous cortisol disappears from the plasma more rapidly in anxious than in normal subjects. Despite the greater excretion of endogenous 17-OHCS in anxious patients, their excretion of these steroids following intravenous cortisol is subnormal. They appear to produce cortisol at a faster rate than do normal subjects.

Hammond, W. G., Vandam, L. D., Davis, J. M., Carter, R. D., Ball, M. R., Moore, F. D.: "Studies in surgical endocrinology. IV. Anesthetic agents as stimuli to change in corticosteroids and metabolism." *Ann. Surg.* **148**: 199-211 (1958). C57,405/58

"Preoperative apprehension and preanesthetic medication were not associated with elevations of the free blood 17-OHCS."

Persky, H., Maroc, J., Conrad, E., Breejen, A. D.: "Blood corticotropin and adrenal weight-maintenance factor levels of anxious patients and normal subjects." *Psychosom. Med.* **21**: 379-386 (1959).

D2,894/59

In anxious hypercorticoid patients, the plasma level of "precorticotropin or adrenal weight-maintenance factor (AWMF)" is more significantly increased than that of the classic ACTH or ascorbic acid depletion factor (AADF).

Mason, J. W.: "Psychological influences on the pituitary-adrenal cortical system. *Recent Prog. Horm. Res.* **15**: 345-389 (1959).

C71,311/59

Review lecture on the stressor effects of psychologic stimuli upon the pituitary-adrenocortical axis in man and monkeys. Among the factors discussed are housing conditions, environmental activity, "first-experience" situations (such as the first time monkeys are handled or placed in a new cage, avoidance procedures, sleep deprivation and diurnal variations. The general conclusion drawn is "that the pituitary-adrenal cortical system is remarkably sensitive to psychological influences in both man and the monkey, and that ACTH release occurs, not in association with a specific emotional state, but rather with a wide variety of emotional disturbances which may have the relatively undifferentiated element of distress or arousal" (9 refs. only, but an extensive discussion by the audience).

Persky, H., Korchin, S. J., Basowitz, H., Board, F. A., Sabshin, M., Hamburg, D. A., Grinker, R. R.: "Effect of two psychological stresses on adrenocortical function." *Arch. Neurol. Psychiatry* **81**: 219-226 (1959).

J3,935/59

In anxiety-prone psychiatric patients, anticipation of an anxiety-evoking interview or a perceptual distortion test caused a greater increase in plasma cortisol and urinary corticoid levels than did the experiment itself.

Levitt, E. E., Persky, H.: "Relation of Rorschach factors and plasma hydrocortisone level in hypnotically induced anxiety." *Psychosom. Med.* **22**: 218-223 (1960).

C88,083/60

Melick, R.: "Changes in urinary steroid excretion during examinations." *Australas. Ann. Med.* **9**: 200-203 (1960). D1,916/60

During examination periods, students' urinary corticoid excretion is increased throughout day and night.

Korchin, S. J., Herz, M.: "Differential effects of 'shame' and 'disintegrative' threats on emotional and adrenocortical functioning." *Arch. Gen. Psychiatry* **2**: 640-651 (1960).

D2,941/60

In healthy young men the psychogenic stress of shame, threat (scrambled sentences) or disintegrative threat (picture description) caused a rise in plasma cortisol roughly proportional to the manifest signs of emotional arousal.

Hodges, J. R., Jones, M. T., Stockham, M. A.: "Effect of emotion on blood corticotrophin and cortisol concentrations in man." *Nature* **193**: 1187-1188 (1962).

D20,817/62

In students, blood ACTH and cortisol levels were greatly elevated during the emotional stress of oral examinations.

Fiorica, V., Muehl, S.: "Relationship between plasma levels of 17-hydroxy-corticosteroids (17-OHCS) and a psychological measure of manifest anxiety." *Psychosom. Med.* **24**: 596-599 (1962).

D46,952/62

In normal (nonhospitalized) people, plasma 17-OHCS levels are raised under anxiety-creating conditions.

Hamburg, D.A.: "Plasma and urinary corticosteroid levels in naturally occurring psychologic stresses." In: Korey, S.R., Pope, A., Robins, E., *Ultrastructure and Metabolism of the Nervous System*, pp. 406-413. Baltimore: Williams & Wilkins, 1962.

J5,097/62

Review of the literature showing that even minor psychogenic stressors (academic exams, surgical interventions or mere anticipation of these) increase plasma and urinary glucocorticoid levels.

Davis, J., Morrill, R., Fawcett, J., Upton, V., Bondy, P. K., Spiro, H. M.: "Apprehension and elevated serum cortisol levels." *J. Psychosom. Res.* **6**: 83-86 (1962).

J11,154/62

In subjects unfamiliar with blood drawing procedures, the blood cortisol levels rise much more than in those for whom this is not a "first time" experience. Presumably, "data taken in a so-called 'control' situation may not provide a true baseline value, particularly if the subjects are not familiar with the procedures, but rather may be elevated due to the stress of the 'first time' effect."

Cooper, C. E., Nelson, D. H.: "ACTH levels in plasma in preoperative and surgically stressed patients." *J. Clin. Invest.* **41**: 1599-1605 (1962) (33 refs.). D29,555/62

Wadeson, R. W., Mason, J. W., Hamburg, D. A., Handlon, J. H.: "Plasma and urinary 17-OHCS responses to motion pictures." *Arch. Gen. Psychiatry* **9**: 146-156 (1963).

E22,691/63

"Significant elevations in plasma 17-OHCS levels were observed during a war movie in one group. Marked decreases in plasma 17-OHCS levels occurred rather consistently during the viewing of Disney nature films. Plasma and urinary values did not consistently correlate well, and plasma measurements were regarded as more reliable."

Jensen, C. C., Ek, J. I.: "The excretion of certain adrenal steroids during mental stress in healthy persons." *Acta Psychiatr. Scand.* **38** No. 4: 302-306 (1963). G11,917/63

Analysis of the different corticoid fractions in students during the emotional stress of examinations.

Mason, J. W., Sachar, E. J., Fishman, J. R., Hamburg, D. A., Handlon, J. H.: "Corticosteroid responses to hospital admission." *Arch. Gen. Psychiatry* **13**: 1-8 (1965). G31,187/65

Mefferd, R. B. Jr., Wieland, B. A.: "Comparison of responses to anticipated stress and stress." *Psychosom. Med.* **28**: 795-807 (1966). G42,966/66

Young airmen were exposed to actual or

anticipated severe hypoxia, with catecholamine and corticoid secretion as well as other metabolic changes being measured as objective indicators of stress. There were great individual variations in the response to anticipated stress: "some reacted hardly at all, while others had an alarm reaction. Upon actual exposure to hypoxia (except for those compensatory adaptations specific to hypoxia) these general responses simply increased in magnitude in all subjects, i.e., they maintained their rank-order positions during the stress."

Bridges, P. K., Jones, M. T.: "Personality, physique and the adrenocortical response to a psychological stress." *Br. J. Psychiatry* **113**: 601-605 (1967). G47,391/67

In male medical students, plasma cortisol levels rose considerably during oral examinations.

Mason, J. W.: "A review of psychoendocrine research on the pituitary adrenal cortical system." *Psychosom. Med.* **30**: 576-607 (1968).

H29,040/68

Excellent review on the effect of psychologic stimuli and psychiatric disease upon the pituitary-adrenocortical axis. "Elevation of 17-OHCS levels is not related to a highly specific affective state, but rather appears to reflect a relatively undifferentiated state of emotional arousal or involvement, perhaps in anticipation of activity or coping. The elements of novelty, uncertainty, or unpredictability are particularly potent influences in eliciting 17-OHCS elevations" (222 refs.).

Oyama, T., Shibata, S., Kimura, K., Takazawa, T.: "Objective evaluation of pentobarbital as preanesthetic medication: effect on adrenocortical function." *Anesth. Analg. (Cleve.)* **48**: 367-372 (1969).

G66,262/69

In a series of surgical patients "preoperative emotional reactions such as fear and apprehension significantly elevated the plasma cortisol levels on the day of operation, just before induction."

Nyakas, C., Endrőczi, E.: "Activation of pituitary-adrenocortical function by conditioned fear in infant and adult rats." *Acta Physiol. Acad. Sci. Hung.* **36**: 401-405 (1969).

G76,185/69

In rats, conditioned fear was induced by association of tactile and acoustic stimuli with electric shocks. The latter caused a significant decrease in adrenal ascorbic acid in

fourteen-day-old rats, whereas conditioned fear had no such effect in rats at that age but was demonstrable in eighteen-day-old rats. The electric shocks were more effective than conditioned fear during the third week, but a reversal in the magnitude of stimulus response rates was observed in adults.

Weiss, J. M., McEwen, B. S., Silva, M. T. A., Kalkut, M. F.: "Pituitary-adrenal influences on fear responding." *Science* **163**: 197-199 (1969). H5,347/69

In passive avoidance situations, hypophysectomized rats show less, and adrenalectomized rats more, fear than normal. This may be due to the fact that the hypophysectomized rat lacks ACTH which increases arousal, whereas adrenalectomy enhances ACTH production. Presumably, ACTH and glucocorticoids have opposite effects on the regulation of fear-motivated behavior.

Weiss, J. M., McEwen, B. S., Silva, M. T., Kalkut, M.: "Pituitary-adrenal alterations and fear responding." *Am. J. Physiol.* **218**: 864-868 (1970). H21,817/70

Hypophysectomy diminishes the avoidance behavior of the rat while adrenalectomy increases it. ACTH enhances the decreased avoidance behavior of the hypophysectomized rat, and corticosterone reduces the supernormal response of the adrenalectomized rat. "It is suggested that ACTH increases excitability which leads to an increase in generalized fear or anxiety in fear situations, while corticosterone counteracts this influence because it acts to restore a normal level of excitability."

Katz, J. L., Weiner, H., Gallagher, T. F., Hellman, L.: "Stress, distress, and ego defenses. Psychoendocrine response to impending breast tumor biopsy." *Arch. Gen. Psychiatry* **23**: 131-142 (1970). G77,008/70

Women waiting for breast tumor biopsy showed widely differing psychologic defense patterns and anxiety. The associated corticoid excretion also varied considerably and was only roughly proportional to the psychiatric score that was regarded as indicative of stress.

Bloch, S., Brackenridge, C. J.: "Psychological, performance and biochemical factors in medical students under examination stress." *J. Psychosom. Res.* **16**: 25-33 (1972). J10,655/72

In medical students undergoing stressful oral examinations, females showed higher

emotionality and lower uric acid levels. "Scores on worry and emotionality, two components of test anxiety, and two self-ratings of success achieved and emotional interference experienced during the test situation, were all significantly interrelated. The most prominent psychological-biochemical relationship found was the positive one between cortisol and emotionality. Cholesterol was negatively related to self-rating of success." Furthermore, plasma cholesterol levels were inversely, while uric acid concentrations were directly, related to achievement (43 refs.).

Bridges, P. K., Jones, M. T.: "Relationships between some psychological assessments, body-build, and physiological stress responses." *J. Neurol. Neurosurg. Psychiatry* **36**: 839-845 (1973). J7,429/73

During oral academic examinations, constitutional factors greatly influenced the stress reaction. "Students of primarily linear physique had significantly higher plasma corticosteroid values than the predominantly muscular subjects at the time of the examination, as found previously. They also had significantly higher analogue measures of the degree of anxiety experienced at the examination (assessed both by the subject and by an observer)."

Bridges, P. K.: "Practical aspects of the use of some psychological tests of anxiety in a situation of stress." *Br. J. Psychiatry* **123**: 587-596 (1973). J8,356/73

In students undergoing the stress of examinations, respiration and heart rate, blood pressure, plasma corticoids, 17-KGS and urine flow were used as "physiologic variables" to be correlated with different psychologic tests, namely: the Taylor Manifest Anxiety Scale (TMAS), the Minnesota Multiphasic Personality Inventory (MMPI), the Eysenck Personality Inventory (EPI), the Institute for Personality and Ability Testing (IPAT) Anxiety Scale and the Stimulus-Response Inventory (S-R Inventory). "The psychological instruments used showed close relationships together, but there were few associations between the overall psychological test results and the physiological responses. The linear analogue scale is a useful measure of situational anxiety. The other tests used purported to be measures of trait anxiety and should therefore have been relatively stable, but most were found to increase significantly when completed by subjects during states of anxiety."

Bassett, J. R., Cairncross, K. D., King, M. G.: "Parameters of novelty, shock predictability and response contingency in corticosterone release in the rat." *Physiol. Behav.* **10**: 901-907 (1973). J4,385/73

Houser, V. P., Paré, W. P.: "Long-term conditioned fear modification in the dog as measured by changes in urinary 11-hydroxycorticosteroids, heart rate and behavior." *Pavlovian J. Biol. Sci.* **9**: 85-96 (1974).

J12,193/74

→**STH.** Greenwood, F. C., Landon, J.: "Growth hormone secretion in response to stress in man." *Nature* **210**: 540-541 (1966).

F65,986/66

In man, anxiety-causing emotional stress or injection of pyrogen (kind not specified) increased plasma STH levels.

Mason, J. W., Wool, M. S., Wherry, F. E., Pennington, L. L., Brady, J. V., Beer, B.: "Plasma growth hormone response to avoidance sessions in the monkey." *Psychosom. Med.* **30**: 760-773 (1968). H6,463/68

In rhesus monkeys, plasma immunoreactive STH levels usually rise during conditioned avoidance sessions. Venipuncture in itself tends to elevate the "baseline" level (45 refs.).

Greene, W. A., Conron, G., Schalch, D. S., Schreiner, B. F.: "Psychologic correlates of growth hormone and adrenal secretory responses of patients undergoing cardiac catheterization." *Psychosom. Med.* **32**: 599-614 (1970). G80,365/70

In patients undergoing cardiac catheterization, "behavioral differences in categories of affect, arousal and degree of interpersonal engagement were used to reliably delineate four major types of psychologic reaction designated anxious-engaged, anxious-not-engaged, depressed and calm. There were no elevations of cortisol or growth hormone during the procedure in either the calm or the depressed patients. Anxious-not-engaged patients showed major elevations of both cortisol and growth hormone. All the anxious-engaged patients showed initial high and even increasing levels of cortisol but no increases in growth hormone."

→**TTH.** Kracht, J., Spaethe, M.: "Ueber Wechselbeziehungen zwischen Schilddrüse und Nebennierenrinde. II. Mitteilg. Untersuchungen über den 'Hypophysenhemmstoff' p-Oxypropiophenon" (Interrelation between

the thyroid and the adrenal cortex. II. Report: Studies on the "hypophyseal inhibitor" p-oxypropiophenone). *Virchows Arch. [Pathol. Anat.]* **323**: 629-644 (1953).

B85,143/53

Wild rabbits respond to frightening stimuli not only with adrenocortical enlargement, but also with a marked discharge of TTH which causes thyroid hypertrophy. This peculiar response can be prevented by hypophsectomy or methythiouracil.

Kracht, J., Spaethe, M.: "Ueber Wechselbeziehungen zwischen Schilddrüse und Nebennierenrinde. III. Mitt. Die thyreotrope Belastungsreaktion" (Interrelation between the thyroid and the adrenal cortex. III. Report: The thyrotropic stress reaction). *Virchows Arch. [Pathol. Anat.]* **324**: 83-109 (1953).

B87,399/53

In wild rabbits, fear produces an acute discharge of TTH, often with an actual inhibition of ACTH secretion. "The symptomatology and the cause of fear thyrotoxicosis can be classified in terms of the phases of the alarm reaction, resistance, and exhaustion (Selye). Increased thyrotropic function causes inhibition of ACTH secretion."

Gupta, R. C., Prasad, G. C., Udupa, K. N.: "Experimental production of thyrotoxicosis." *5th Asia and Oceania Congr. Endocr.*, p. 178. Chandigarh, India, 1974. H82,223/74

Rats exposed to fear by keeping them in front of a dog's cage showed enhanced ^{131}I uptake and increased PBI with histologic changes in the thyroid indicative of thyrotoxicosis. Serum cholesterol and body weight were lowered. "These observations suggest that experimental thyrotoxicosis can be produced in animals using this method."

→**Other Hormones and Hormone-like Substances.** Connell, A. M., Cooper, J., Redfearn, J. W.: "The contrasting effects of emotional tension and physical exercise on the excretion of 17-ketogenic steroids and 17-ketosteroids." *Acta Endocrinol.* **27**: 179-194 (1958). C47,363/58

In a group of medical students, the psychogenic stress of an important examination significantly increased 17-KGS and slightly raised 17-KS excretion. Muscular activity (treadmill exercise, route march) elicited a moderate decrease in 17-KS and no marked change in 17-KGS elimination. "It is suggested that emotional stress causes an increase in the formation of adrenal cortical hormones; this formation is in preparation

for the physical stress and effort which, under 'natural' conditions, could be expected to follow on the initial emotional strain."

Handlon, J. H.: "Hormonal activity and individual responses to stresses and easements in everyday living." In: Roessler, R. and Greenfield, N. S., *Physiological Correlates of Psychological Disorder*, pp. 157-170. Madison: University of Wisconsin Press, 1962.

J11,133/67

→**Metabolites.** Folin, O., Denis, W., Smillie, W. G.: "Some observations on 'emotional glycosuria' in man. *J. Biol. Chem.* **17**: 519-520 (1914). 58,703/14

Among students undergoing academic examinations, 18 percent exhibited at least traces of sugar in the urine. Hence "mental and emotional strain may produce temporary glycosuria in man."

Rydin, H., Verney, E. B.: "The inhibition of water-diuresis by emotional stress and by muscular exercise." *Q. J. Exp. Physiol.* **27**: 343-374 (1938).

A14,575/38

In dogs, emotional excitement and muscular exercise inhibit diuresis. This response is unaltered by transection of the renal nerves, extirpation of one adrenal and denervation of the other or by decentralization of the whole abdominal sympathetic system with removal of ganglia L2 to S1 inclusive. The course of this inhibition is matched by intravenous vasopressin. "The post-pituitary equivalent of this stress in terms of the standard powder is of the order of 1 µg."

Schneider, R. A., Zangari, V. M.: "Variations in clotting time, relative viscosity, and other physicochemical properties of the blood accompanying physical and emotional stress in the normotensive and hypertensive subject." *Psychosom. Med.* **13**: 290-303 (1951).

B62,983/51

Review on *blood clotting* changes induced in normotensive and hypertensive individuals by various stressors (30 refs.).

Gitelson, S., Tiberin, P.: "Effect of emotional stress on the blood pyruvic acid level." *Acta Endocrinol. (Kbh.)* **11**: 345-350 (1952).

B76,933/52

In patients showing obvious signs of anxiety before surgery, the blood *pyruvic acid* level rises. "It is suggested that hyperpyruvicism occurring in these cases is the result of emotional stress caused by fear of operation and is part of the general 'alarm reaction'."

Basowitz, H., Korchin, S. J., Grinker, R. R.: "Anxiety in a life stress." *J. Psychol.* **38**: 503-510 (1954). B29,178/54

Earlier research has shown that subjects having free anxiety (a feeling of intense dread and foreboding with generalized undirected apprehensiveness) exhibited an elevated *hippuric acid* tolerance in the absence of other evidence of liver dysfunction. Moreover, as anxiety is reduced, hippuric acid synthesis is lowered. In the present study, persons with initially elevated hippuric acid tolerance developed higher levels of anxiety under the stress of paratroop training than those with originally low values, although prior to training the two groups were indistinguishable in their self-ratings of anxiety. Hippuric acid elimination not only distinguishes between neurotics with free anxiety and normal persons, but also shows that "normal individuals whose excretion values are very high, although still below levels typifying the condition of free anxiety, are prone toward heightened anxiety in a life stress."

Hetzel, B. S., Schottstaedt, W. W., Grace, W. J., Wolff, H. G.: "Changes in urinary 17-hydroxycorticosteroid excretion during stressful life experiences in man." *J. Clin. Endocrinol. Metab.* **15**: 1057-1068 (1955).

C8,424/55

In patients, a one-hour discussion of "stressful subjects" caused diuresis with increased 17-OHCS, *nitrogen*, *sodium* and *potassium* elimination.

Schwartz, T. B., Shields, D. R.: "Urinary excretion of formaldehydogenic steroids and creatinine. A reflection of emotional tension." *Psychosom. Med.* **18**: 159-172 (1956).

C25,345/56

In students undergoing stressful final examinations, increased urinary corticoid excretion occurs fairly regularly but urinary volume and *creatinine* excretion are not clearly related to the stressor.

Wertlake, P. T., Wilcox, A. A., Haley, M. I., Peterson, J. E.: "Relationship of mental and emotional stress to serum cholesterol

levels." *Proc. Soc. Exp. Biol. Med.* **97**: 163-165 (1958). C47,228/58

In male medical students the mental stress of examinations caused a considerable increase in serum *cholesterol*, which is considered to be a manifestation of the G.A.S.

Thomas, C. B., Murphy, E. A.: "Further studies on cholesterol levels in the Johns Hopkins medical students: the effect of stress at examinations." *J. Chronic Dis.* **8**: 661-668 (1958). C80,790/58

In fifty-two male medical students, serum cholesterol values rose whereas blood eosinophils decreased during an anatomy examination. "Stress such as accompanies the first few weeks of medical school or important final examinations is accompanied by a significant mean rise in *cholesterol* level."

Grundy, S. M., Griffin, A. C.: "Effects of periodic mental stress on serum cholesterol levels." *Circulation* **19**: 496-498 (1959).

C66,837/59

Blood *cholesterol* levels in male medical students rose significantly during final examinations.

Dreyfuss, F., Czaczkes, J. W.: "Blood cholesterol and uric acid of healthy medical students under the stress of an examination." *Arch. Intern. Med.* **103**: 708-711 (1959).

C81,688/59

In medical students, the psychic stress of examinations raised the serum *cholesterol* levels. "The α -, β -*lipoprotein* distribution of blood cholesterol seemed to show that the increased amount of cholesterol tended to accumulate in the α -fraction. Blood uric acid levels remained approximately unchanged" (25 refs.).

Grundy, S. M., Griffin, A. C.: "Relationship of periodic mental stress to serum lipoprotein and cholesterol levels." *J.A.M.A.* **171**: 1794-1796 (1959). C86,084/59

In medical students, the psychogenic stress of examinations caused a rise in plasma *cholesterol* and low-density *lipoprotein* levels.

Wolf, S., McCabe, W. R., Yamamoto, J., Adsett, C. A., Schottstaedt, W. W.: "Changes in serum lipids in relation to emotional stress during rigid control of diet and exercise." *Circulation* **26**: 379-387 (1962).

J10,367/62

Striking increases in serum *cholesterol* and *triglycerides* occurred in people on a constant diet upon exposure to various situations inducing anxiety, including difficulties in the

family, on the job, and so on. Stress interviews caused such changes within sixty minutes. "No inferences are drawn with respect to the significance of emotional stress in the pathogenesis of coronary atherosclerosis or myocardial infarction, but it is clear that the mechanisms that govern the serum concentration of certain lipids are connected with and capable of responding to impulses from the higher centers of the brain."

Back, K. W., Bogdonoff, M. D.: "Plasma lipid responses to leadership, conformity, and deviation." In: Liederman, P. H. and Shapiro, D., *Psychobiological Approaches to Social Behavior*, pp. 24-42. Stanford, Cal.: Stanford University Press, 1964.

J11,130/64

Detailed review on plasma *FFA* as an objective indicator of stress in man, particularly in social interrelations. Plasma *FFA* levels are very sensitive to changes in autonomic nervous activity and are especially useful in assessing situational demands and group interactions.

Goldberg, G. A., Nikitin, U. P.: "Changes in blood lipids in physicians during examinations." *Ter. Arkh.* **37** No. 5: 71-74 (1965) (Russian).

J22,374/65

During examinations, physicians exhibit an increase in blood *cholesterol*. "The level of lecithin and the lecithin/*cholesterol* ratio decrease during examinations. There is a reliable correlation between changes of the cholesterol titer in the blood serum and the arterial pressure and pulse."

Scrimshaw, N. S., Habicht, J. P., Piché, M. L., Cholakos, B., Arroyave, G.: "Protein metabolism of young men during university examinations." *Am. J. Clin. Nutr.* **18**: 321-324 (1966).

Vandenbergh, R. L., Sussman, K. E., Titus, C. C.: "Effects of hypnotically induced acute emotional stress on *carbohydrate* and *lipid* metabolism in patients with diabetes mellitus." *Psychosom. Med.* **28**: 382-390 (1966).

G40,600/66

Back, K. W., Bogdonoff, M. D.: "Buffer conditions in experimental stress." *Behav. Sci.* **12**: 384-390 (1967).

J9,369/67

Detailed report on the conditions under which psychologic stimuli, particularly those causing anxiety, raise the plasma *FFA* level in man.

Carlson, L. A., Levi, L., Orö, L.: "Plasma lipids and urinary excretion of catechol-

amines in man during experimentally induced emotional stress, and their modification by nicotinic acid." *J. Clin. Invest.* **47**: 1795-1805 (1968). H1,440/68

In male volunteers, emotional stressors (dazzling light, standardized criticism, sorting steel balls of different sizes) caused a rise in plasma FFA and triglycerides and greater catecholamine excretion. Concurrent treatment with nicotinic acid prevented the elevation in FFA and triglycerides but not the stressor-induced increase in catecholamine elimination or the associated rise in heart rate and blood pressure.

Beneš, V., Hrubes, V.: "Serum free fatty acid level after an experimentally induced emotional stress and its modification by nicotinic acid in rats with different characteristics of higher nervous activity." *Activ. Nerv. Sup. (Praha)* **10**: 395-399 (1968). J11,743/68

The fear of intermittent electric shocks elevated serum FFA, particularly in rats with extremely low spontaneous exploratory activity. Intraperitoneal nicotinic acid completely blocked this change.

Yordanova, L., Gotsev, T.: "Alterations in the enzyme activity of students with increased body temperature during examinations." *J. Physiol. (Paris)* **63**: 463-464 (1971). J20,215/71

Among students under "examination stress," the most outstanding objective changes were tachycardia, hypertension, dilatation of the pupils, increased intraocular pressure, sweating, alterations in erythrocytes and platelets, a rise in body temperature and in the blood levels of carbonic anhydrase and cholinesterase.

Kakizaki, T.: "Stress response during mental task. 2. Biochemical response of human subjects under arithmetical calculation tasks." *Ind. Health (Kawasaki)* **9**: 105-112 (1971). J10,263/71

Kakizaki, T.: "3. Three factors affecting the stress responses in man under arithmetical calculation tasks." *Ind. Health (Kawasaki)* **9**: 153-161 (1971). H79,739/71

Kakizaki, T.: "4. A principal factor inducing the stress responses in man under arithmetical calculation tasks." *Ind. Health (Kawasaki)* **9**: 162-170 (1971). J10,264/71

Kakizaki, T.: "5. Effect of unpleasant feeling toward task performance on the stress response to arithmetical calculation tasks."

Ind. Health (Kawasaki) **11**: 8-18 (1973). J10,265/73

Kakizaki, T. "6. Effect of unpleasant feeling due to pure sound noise on the stress response during arithmetical calculation tasks." *Ind. Health (Kawasaki)* **11**: 77-83 (1973). J10,266/73

Detailed description of a test in which responses (corticoid, FFA, blood pressure, electrolytes, blood proteins, cholesterol and so on) are used as indicators of the stress produced by arithmetic calculations. Both the difficulty and the duration of the task are of significance, but curiously, several interfering unpleasant factors (for example, sound) do not significantly affect the results.

Critz, J. B.: "The effect of the mental stress of examination writing on plasma enzyme activity" (abstracted). *Physiologist* **17**: 203 (1974). H89,885/74

→**Morphology.** Mora, J. M., Amtman, L. E., Hoffman, S. J.: "Effect of mental and emotional states on the leukocyte count." *J.A.M.A.* **86**: 945-946 (1926). B26,023/26

In man, various "mental and emotional states" elicited polymorphonuclear leukocytosis. The practical importance of this phenomenon lies in the fact that it "may have to be considered as a not infrequent cause of leukocytosis, especially in operative cases, and may be confused with infective or other types of leukocytic change." [Published ten years before the formulation of the stress concept! (H. S.).]

Humphreys, R. J., Raab, W.: "Response of circulating eosinophils to norepinephrine, epinephrine and emotional stress in humans." *Proc. Soc. Exp. Biol. Med.* **74**: 302-303 (1950). B49,646/50

In medical students, the stress of examination caused profound eosinopenia; this response was much more readily duplicated by EP than by NEP.

Renold, A. E., Quigley, T. B., Kennard, H. E., Thorn, G. W.: "Reaction of the adrenal cortex to physical and emotional stress in college oarsmen." *N. Engl. J. Med.* **244**: 754-757 (1951). B65,108/51

Harvard-Yale boat race crews showed a marked eosinopenia which was interpreted as a sign of stress-induced corticoid secretion. Muscular effort was not the only stressor, for the coxswain likewise responded with pronounced eosinopenia although he was almost exclusively under emotional stress.

Dreyfuss, F., Feldman, S.: "Eosinopenia induced by emotional stress." *Acta Med. Scand.* **144**: 107-113 (1952). B82,162/52

Eosinopenia occurred in medical students just before examinations and sometimes persisted afterwards. The same phenomenon was noted in women during the anxiety related to diagnostic curettage. It was "ascribed to the considerable emotional stress undergone in the two situations."

Mahl, G. F., Brody, E. B.: "Chronic anxiety symptomatology, experimental stress, and HCl secretion." *Arch. Neurol. Psychiatry* **71**: 314-325 (1954). J13,190/54

Review of the literature on the effects of stress upon gastric acidity in animals and man. Among patients, chronic anxiety is associated with increased gastric hydrochloric acid secretion and may be related to ulcerogenesis (18 refs.).

Markkanen, A., Pekkarinen, A., Pulkkinen, K., Simola, P. E.: "On the emotional eosinopenic reaction caused by examination." *Acta Physiol. Scand.* **35**: 225-239 (1956). C12,841/56

Kerr, A. C.: "The effect of mental stress on the eosinophil leucocyte count in man." *Q. J. Exp. Physiol.* **41**: 18-24 (1956).

C35,686/56

Eosinopenia was observed in students during examinations in dental surgery. Controls performing similar operations in daily practice showed no such changes in blood counts.

Hill, S. R. Jr., Goetz, F. C., Fox, H. M., Murawski, B. J., Krakauer, L. J., Reifenstein, R. W., Gray, S. J., Reddy, W. J., Hedberg, S. E., St. Marc, J. R., Thorn, G. W.: "Studies on adrenocortical and psychological response to stress in man." *Arch. Intern. Med.* **97**: 269-298 (1956). C35,720/56

The intense muscular and psychogenic stressor effect of crew racing caused eosinopenia with increased urinary excretion of 17-OHCS, 17-KS and uropepsin, but signs of adrenal hyperactivity were also obvious during the prerace tension. In earlier studies it was found that eosinopenia developed in both the coxswain and coach during the race; hence "the physical exertion of rowing was not the only stress involved capable of inducing a marked eosinopenia."

McDonald, R. D., Yagi, K.: "A note on eosinopenia as an index of psychological

stress." *Psychosom. Med.* **22**: 149-150 (1960). C84,340/60

In subjects induced to believe that they had accidentally caused serious injury to a companion through misuse of explosives, attempts to repair an inoperative telephone switchboard to call for medical assistance led to pronounced eosinopenia. Controls asked to fix the same switchboard merely as a psychomotor test showed no such change. Hence, eosinopenia appears to be a reliable index of psychogenic stress.

Gollender, M., Law, O. T., Isaacson, R. L.: "Changes in the circulating eosinophil level associated with learned fear: conditioned eosinopenia." *J. Comp. Physiol. Psychol.* **53**: 520-523 (1960). G50,316/60

In rats, intermittent electroshock causes eosinopenia. After conditioning, this reaction can be elicited by mere anticipation of shock.

Milin, R.: "The effect of fright on morphodynamics of testes." *Med. Pregl.* **19**: 453-458 (1966) (Serbo-Croatian). G60,378/66

In hares kept in captivity in the presence of a hunting dog, testicular atrophy occurs as a consequence of fear.

→Nervous System (including performance in general). Cowen, E. L.: "The influence of varying degrees of psychological stress on problem-solving rigidity." *J. Abnorm. Soc. Psychol.* **47** Supp.: 512-519 (1952). B29,093/52

The psychogenic stress of anxiety causes "problem-solving rigidity," defined as the tendency to adhere to an induced method of problem-solving even when this is no longer the most economic means to achieve the goal (24 refs.).

Cowen, E. L.: "Stress reduction and problem-solving rigidity." *J. Consult. Psychol.* **16**: 425-428 (1952). B26,453/52

Subjects were arbitrarily told that they did well or badly in examinations, irrespective of their actual performance. When exposed to a second test, the praised group did significantly better, presumably because their anxiety had diminished (14 refs.).

Lazarus, R. S., Deese, J., Osler, S. F.: "The effects of psychological stress upon performance." *Psychol. Bull.* **49**: 293-317 (1952). B36,729/52

Extensive review on the effects of various psychogenic stress situations upon verbal, perceptual and motor performance. The rela-

tionships to the G.A.S. are only briefly touched upon (46 refs.).

Lazarus, R. S., Eriksen, C. W.: "Effects of failure stress upon skilled performance." *J. Exp. Psychol.* **43**: 100-105 (1952).

E60,272/52

Hamburg, D. A.: "Psychological adaptive processes in life-threatening injuries." *Symposium on Stress*, pp. 222-235. Washington, D. C.: Army Medical Service Graduate School, 1953.

B89,532/53

Detailed discussion of the various mental defense reactions with which people having different psychologic characteristics meet the challenge of life-threatening situations, particularly severe injuries and imminent stress. Among these responses, there are three general types: "those which tend to make the patient feel that his life is not really in danger; those which tend to make him feel unafraid of impending death; and those which tend to make him feel that he will recover. All of these emergency defenses are usually facilitated by the diffuse impairment of brain function often associated with severe injury. This impairment makes it easier for the patient to restrict his awareness, to perceive only what he wants to perceive, and to delay recognition of the threat to life."

Berg, I. A.: "Observations concerning obsessive tunes in normal persons under stress." *J. Clin. Psychol.* **11**: 300-302 (1953).

J8,066/53

Marital discord, financial worries, academic failure, vocational indecision and other stressors caused certain persons to experience "tunes in the head" which they could not stop reproducing for long periods.

Hammock, J. C., Prince, A. L.: "Rifle marksmanship as a function of manifest anxiety and situational stress" (abstracted). *Am. Psychol.* **9**: 389-390 (1954).

J13,186/54

Stopol, M. S.: "The consistency of stress tolerance." *J. Pers.* **23**: 13-29 (1954).

B28,524/54

Through the use of the Rorschach and Digit-Symbol tests it was found that: "(a) Tolerance for failure stress and for distraction stress are independent of each other; no significant relationship exists between them. (b) The amount of poststress recovery is positively related to the degree of failure stress and distraction stress tolerance, especially during the second introduction of

stress. (c) Variability of performance during the poststress phase is inversely related to the degree of tolerance for failure stress and distraction stress during the second introduction of stress; no significant relationship exists during the initial administration of stress. (d) During the second administration of stress there is a greater decrement in performance, regardless of the nature of the stress. (e) No significant difference exists between the effects of the particular kinds of failure stress and distraction stress employed in this study if the temporal sequence of presentation is controlled. (f) During the second introduction of stress, generalization occurs in the form of a tendency to respond in a similar manner to both stimulus conditions of stress and nonstress."

Parsons, O. A., Phillips, L., Lane, J. E.: "Performance on the same psychomotor task under different stressful conditions." *J. Psychol.* **38**: 457-466 (1954).

E84,297/54

J13,188/54

Kubzansky, P. E.: "Anxiety, stress, and flicker fusion measurements" (abstracted). *Am. Psychol.* **9**: 410-411 (1954).

J13,187/54

"There were no effects in the flicker measures attributable to stress."

Beam, J. C.: "Serial learning and conditioning under real-life stress." *J. Abnorm. Soc. Psychol.* **51**: 543-551 (1955).

J10,605/55

The stress of academic examinations seriously interfered with serial learning of a list of nonsense syllables. Stress was appraised by the palmar-sweat index.

Smock, C. D.: "The influence of psychological stress on the 'intolerance of ambiguity'." *J. Abnorm. Soc. Psychol.* **50**: 177-182 (1955).

B29,284/55

In university students of both sexes, feelings of anxiety inspired by the examiner produced an intolerance of ambiguity, as manifested by a tendency to attempt solving problems quickly on the basis of insufficient evidence (13 refs.).

Smock, C. D.: "The influence of stress on the perception of incongruity." *J. Abnorm. Soc. Psychol.* **50**: 354-356 (1955).

B29,336/55

Psychologic stress results in a special intolerance of ambiguity and incongruity. The latter is defined as a stimulus configuration composed of elements that conflict with the expectancies of the individual. Psychogenic stress causes "a tendency to adhere to expectancies (prerecognition hypothesis) in ambiguous task situations. From these two sets of data it is inferred that stress or anxiety results in cognitive and perceptual processes that tend to preserve a 'familiar' perceptual and behavioral field for the individual." [Here again, the causative agent is difficult to identify as nonspecific and hence as a stressor in the classic sense of the word. It might be referred to more accurately as strain (H.S.).]

French, E. G.: "Interrelation among some measures of rigidity under stress and non-stress conditions." *J. Abnorm. Soc. Psychol.* **51**: 114-118 (1955). J11,475/55

In testing Air Force personnel it was found that various psychogenic stressors did not increase rigidity in problem solving (16 refs.).

Wiener, M.: "The effects of two experimental counseling techniques on performances impaired by induced stress." *J. Abnorm. Soc. Psychol.* **51**: 565-572 (1955).

J13,309/55

Farber, I. E., Spence, K. W.: "Effects of anxiety, stress, and task variables on reaction time." *J. Pers.* **25**: 1-18 (1956).

B29,418/56

In man, variations in the degree of anxiety did not consistently affect reaction time to visual stimuli (41 refs.).

Pronko, N. H., Leith, W. R.: "Behavior under stress: a study of its disintegration." *Psychol. Rep.* **2**: 205-222 (1956).

B28,732/56

Review of the literature and personal observations on the effects of psychogenic stress (particularly anxiety) upon perception and performance in various tests, some of which are described in detail (29 refs.).

Davidson, W. Z., Andrews, T. G., Ross, S.: "Effects of stress and anxiety on continuous high-speed color naming." *J. Exp. Psychol.* **52**: 13-17 (1956).

J13,313/56

Kalish, H. I., Garmezy, N., Rodnick, E. H., Bleke, R. C.: "The effects of anxiety and experimentally-induced stress on verbal learning." *J. Gen. Psychol.* **59**: 87-95 (1958).

B66,644/58

Review of the literature and personal observations on the effect of anxiety as a stressor on verbal learning in subjects with high and low anxiety (TMAS) (17 refs.). [It is questionable whether such psychologic effects of certain mental states should be ascribed to stress in the classic sense, since there is no evidence of their nonspecificity. It might be preferable to refer to these and any other specific physiologic demands as "strain" (H.S.).]

Taylor, J. A.: "The effects of anxiety level and psychological stress on verbal learning." *J. Abnorm. Soc. Psychol.* **57**: 55-60 (1958).

J2,414/58

Tests using the MAS showed that while "high anxiety subjects under neutral instructions were significantly superior to the low anxious, as predicted, and the subjects operating under stress were inferior to their neutral controls, the predicted interaction between anxiety level and stress was not found."

Katchmar, L. T., Ross, S., Andrews, T. G.: "Effects of stress and anxiety on performance of a complex verbal-coding task." *J. Exp. Psychol.* **55**: 559-564 (1958). J10,039/58

Psychologic study on the effects of anxiety upon performance. No attempt is made to coordinate these findings with the somatic manifestations of the G.A.S.

Dowis, J. L., Diethelm, O.: "Anxiety, stress, and thinking: an experimental investigation." *J. Psychol.* **45**: 227-238 (1958).

J10,609/58

In man, experimentally induced anxiety interferes with problem solving as indicated by various tests.

Caron, A. J., Wallach, M. A.: "Personality determinants of repressive and obsessive reactions to failure-stress." *J. Abnorm. Soc. Psychol.* **59**: 236-245 (1959). G82,249/59

Harvard freshmen received a complete battery of tests used in factor analysis either under normal conditions or when submitted to a failure-stress. Their performance was related to their personality characteristics, particularly ego strength, need achievement and hysteria. The influence of these characteristics upon repressive and obsessive forms of defense is discussed.

Visotsky, H. M., Hamburg, D. A., Goss, M. E., Lebovits, B. Z.: "Coping behavior under extreme stress." *Arch. Gen. Psychiatry* **5**: 423-448 (1961).

J3,934/61

Observations on adaptive behavior (or its failure) in patients with severe poliomyelitis.

Mechanic, D.: *Students Under Stress. A Study in the Social Psychology of Adaptation*, p. 231. Glencoe, Ill.: Free Press, 1962.

E10,421/62

A detailed analysis based mainly on observations of psychogenic stress in students preparing for and taking examinations for the Ph.D. degree. One of the most important objectives of the study was to attempt a correlation between the somatic aspects of the G.A.S. and psychologic stress responses (about 75 excellent references, especially to monographs on psychogenic stress).

Speisman, J. C., Lazarus, R. S., Mordkoff, A., Davison, L.: "Experimental reduction of stress based on ego-defense theory." *J. Abnorm. Soc. Psychol.* **68**: 367-380 (1964).

J7,194/64

The same anxiety-producing film was shown with three different sound tracks, one of which was designed to increase its stressor effect by emphasizing threatening aspects while the other two were based upon the theory of ego defense, encouraging defensive and cognitive interpretations. Skin conductance (used as evidence of psychogenic stress) was decreased by the defensive sound tracks, "permitting the conclusion that the same visual stimulus varies in the amount of stress produced depending upon the nature of the cognitive appraisal the person makes regarding its significance for him."

Suinn, R. M., Geiger, J.: "Stress and the stability of self- and other attitudes." *J. Gen. Psychol.* **73**: 177-180 (1965). J10,615/65

In students undergoing examinations, "the prediction that anxiety increases the correlation between self-acceptance and acceptance of others was not confirmed."

Lazarus, R. S.: *Psychological Stress and the Coping Process*, p. 466. New York, Toronto and London: McGraw-Hill, 1966.

E750/66

Detailed and very competent discussion of stress in relation to psychology, with special reference to the problem of coping with threatening situations. Correlations between the adaptive mechanisms of the CNS and the G.A.S. are given adequate attention throughout this volume.

Feather, N. T.: "Effects of prior success and failure on expectations of success and subsequent performance." *J. Pers. Soc. Psychol.* **3**: 287-298 (1966). J11,249/66

Nomikos, M. S., Opton, E. Jr., Averill, J. R., Lazarus, R. S.: "Surprise versus suspense in the production of stress reaction." *J. Pers. Soc. Psychol.* **8**: 204-208 (1968).

J8,972/68

In viewers of films depicting wood-mill accidents that occurred either unexpectedly or after long anticipation and suspense, it was found that "long anticipation was more stressful than short anticipation, consistently producing higher levels of autonomic disturbance. Moreover, most of the physiological stress reaction occurred during the periods of anticipation, rather than during the actual confrontations with accident scenes." The literature on the comparative stressor effect of exposure to unpleasant experiences with and without forewarning is discussed.

Hackman, J. R.: "Tasks and task performance in research on stress." In: McGrath, J. E., *Social and Psychological Factors in Stress*, pp. 202-237. New York, Chicago and San Francisco: Holt, Rinehart and Winston, 1970.

E10,325/70

Lecture analyzing how task-induced stress relates to behavior.

Cattell, R. B.: "Measurement of neuroticism and anxiety." In: Sahakian, W. S., *Psychopathology Today: Experimentation, Theory and Research*, pp. 173-181. Itasca, Ill.: F E Peacock, 1970.

E10,330/70

In a monograph on psychopathology, this chapter is devoted to the relationship between stress and psychologic changes as its cause or result. Anxiety appears when an individual evades reality and suffers internal conflicts whereas "effort stress" occurs when he forcefully grapples with reality.

Martens, R., Landers, D. M.: "Motor performance under stress: a test of the inverted-U hypothesis." *J. Pers. Soc. Psychol.* **16**: 29-37 (1970).

J12,679/70

High school boys were exposed to various intensities of anxiety by the threat of punishment with electroshock if they performed standard motor tasks poorly. Heart rate, palmar sweat and questionnaire responses served as indicators of stress, and the Children's Manifest Anxiety Scale was used to appraise anxiety. The results "supported the inverted-U hypothesis for the stress factor and the anxiety factor separately." The inverted-U hypothesis states that increased arousal is associated with better performance up to a certain point, after which additional increases in arousal impair performance.

Bey, D. R., Lange, J.: "Waiting wives: women under stress." *Am. J. Psychiatry* **131**: 283-286 (1974). J10,401/74

Description of the psychologic problems met by wives of men ordered into combat.

→**Accident Proneness.** Schulzinger, M. S.: *The Accident Syndrome. The Genesis of Accidental Injury*, p. 234. Springfield, Ill.: Charles C Thomas, 1956. E10,655/56

Monograph concerning statistical data on the frequency of accidents under various conditions, and the factors responsible for accident proneness. No special attention is given to stress as such (73 refs.).

Kerr, W.: "Complementary theories of safety psychology." *J. Soc. Psychol.* **45**: 3-9 (1957). D54,998/57

Discussion of an "adjustment stress theory" which holds that distracting stress increases accident proneness. Literature is cited in which earlier investigators found that the following stress factors significantly correlated with accident rates: employee age, workplace temperature, illumination, comfort of shop, operator congestion, anxiety, alcohol and preexistent disease (24 refs.).

Rogg, S. G.: "The role of emotions in industrial accidents." *Arch. Environ. Health* **3**: 519-522 (1961). D92,957/61

Psychogenic stress predisposes to industrial accidents.

Sachs, B. C.: Psychosomatic aspects of accidents. *Ind. Med. Surg.* **31**: 525-532 (1962). J13,761/62

Brody, L.: "The accident phenomenon." *Person. Admin.* **26**: 11-14 (1963).

D84,924/63

Various types of stressors can cause accident proneness.

Thomae, H.: "Accident and psychological stress." *Int. J. Prod. Res.* **2**: 229-233 (1963). J16,323/63

J16,122/64

Wells, R. L.: Psychosocial influences on accidents. *Arch. Environ. Health* **13**: 496-500 (1966). D99,572/66

General review on the effect of psychogenic stress upon accident proneness.

Selzer, M. L., Rogers, J. E., Kern, S.: "Fatal accidents: the role of psychopathology, social stress, and acute disturbance." *Am. J. Psychiatry* **124**: 1028-1036 (1968).

E84,312/68

"Significantly more psychopathology and social stress were present in 96 drivers causing fatal accidents than in a matched control group." Twenty percent of the drivers had acutely disturbing experiences within six hours of causing a fatal accident (20 refs.).

Neves, F. I.: "Adaptación social y accidentes del trabajo" (Social adaptation and accidents on the job). *Rev. Interamer. Psicol.* **3**: 139-162 (1969). J16,327/69

Review of the literature on the role of psychosocial stressors in accident proneness among manual workers (21 refs.).

Felton, J. S.: "Sensitivity to emotional ill health." *Proc. Ann. Conf. NASA Clin. Dir., Environm. Hlth. Off. Med. Advisors*, New Orleans, La. Oct. 21-23, 1969. Abstracted in *Staff Century Res. Corp. pamphlet* Vol. 2, 923rd Abstr. Arlington, Va. 1973.

J16,125/69

Statistical studies suggest that accident proneness is often referable to intolerable and frustrating conditions at work.

McMurray, L.: "Emotional stress and driving performance: the effect of divorce." *Behav. Res. Highway Safety* **1**: 100-114 (1970).

J16,599/70

Gass, G. Z.: "Hardcore personality and industrial illnesses and accidents." *Ind. Med. Surg.* **39**: 174-178 (1970). J13,408/70

McGuire, F. L.: "A typology of accident proneness." *Behav. Res. Highway Safety* **1**: 26-32 (1970).

J16,598/70

A review of the role of stress in accident proneness, particularly in relation to driving.

Baruch, D.: "Some medical aspects in agricultural flights relating to fatigue among agricultural pilots." *Aerosp. Med.* **41**: 447-450 (1970).

G36,975/70

A study in Israel showed that "as a result of agricultural flights under hard weather conditions there were significant changes in the pilot's body such as loss of weight, increase of body temperature, decrease of eosinophil cells, tendency to decrease of blood sugar level. All these changes in combination with lack of sleep may reduce the alertness of the pilot and may be considered an im-

portant factor in aircraft accidents in agricultural flights."

Andersson, A. L., Nilsson, A., Henriksson, N. G.: "Personality differences between accident-loaded and accident-free young car drivers." *Br. J. Psychol.* **61**: 409-421 (1970). J15,060/70

Henderson, M.: "The accident-prone car driver—does he exist?" *Med. J. Austr.* **2**: 909-912 (1971). J13,987/71

Accident proneness in motor car drivers is positively correlated with their stress experiences in daily life. The concept that certain individuals are inherently accident prone is rejected, but stress increases the probability of accidents in virtually any profession.

Viney, L.: "Accident proneness: some psychological research." *Med. J. Austr.* **2**: 916-918 (1971). J14,016/71

Review of clinical data indicating that previous exposure to stressors increases accident proneness.

Yanowitch, R. E., Mohler, S. R., Nichols, E. A.: "Psychosocial reconstruction inventory: a postdictal instrument in aircraft accident investigation." *Aerosp. Med.* **43**: 551-554 (1972). J14,847/72

Review of data on the role of stress in increasing accident proneness, especially in pilots.

"Problems in occupational safety and health: a critical review of select physical and psychological factors." *Staff Century Res. Corp.* pamphlet, Vol. 2, p. 90, and 1317 Abstr. Arlington, Va. 1973. J13,172/73

Annotated bibliography of 1317 articles concerning occupational safety and accident proneness.

Rodstein, M.: "Accident proneness." *J.A.M.A.* **229**: 1495 (1974). H91,883/74

Concise summary of principal factors responsible for accident proneness under stressful conditions, with special reference to automobile accidents.

→ **Suicide.** Neuringer, C.: "Reactions to interpersonal crises in suicidal individuals." *J. Gen. Psychol.* **71**: 47-55 (1964). J23,844/64

Bunney, W. E. Jr., Fawcett, J. A.: "Possibility of a biochemical test for suicidal potential. An analysis of endocrine findings prior to three suicides." *Arch. Gen. Psychiatry* **13**: 232-239 (1965). J12,529/65

Increased urinary 17-OHCS excretion may be a useful indicator of suicidal intent.

Hoch-Ligeti, C.: "Adrenal cholesterol concentration in cases of suicide." *Fed. Proc.* **25**: 552 (1966). F65,019/66

The highest adrenal cholesterol concentrations were found in patients who committed suicide and in hypertensives, being much above those of persons who died in accidents. Presumably, the changes are related to stress.

Rosenberg, P. H., Latimer, R.: "Suicide attempts by children." *Ment. Hyg.* **50**: 354-359 (1966). J22,930/66

Anxiety about handling stress situations and acute distress owing to frustration are among the most frequent causes of suicide attempts in children.

Bunney, W. E. Jr., Fawcett, J. A., Davis, J. M., Gifford, S.: "Further evaluation of urinary 17-hydroxycorticosteroids in suicidal patients." *Arch. Gen. Psychiatry* **21**: 138-150 (1969). G67,923/69

Urinary 17-OHCS levels were elevated in patients who committed or attempted to commit suicide (16 refs.).

Naftulin, D. H.: "The potentially suicidal patient. Detection and management in office practice." *Calif. Med.* **111** No. 3: 169-176 (1969). J21,184/69

Use of the SPRS in patients under stress.

Krieger, G.: "Biochemical predictors of suicide." *Dis. Nerv. Syst.* **31**: 478-482 (1970). H47,537/70

In psychiatric patients considered to be suicidal risks, a large percentage of those with high plasma cortisol levels subsequently killed themselves. "The elevated plasma cortisol may reflect the vulnerability to suicide and be causative" (17 refs.).

Pichot, P., Menahem, R.: "Constitutional factors in suicide." In: Waldenström, J., Larsson, T. et al., *Suicide and Attempted Suicide (Skandia Sixth International Symposium, 1971)*, pp. 102-113. Stockholm: Nordiska Bokhandelns Förlag, 1972. E10,485/72

A review suggesting a possible association between suicidal tendencies and derangements in corticoid and 5-HT production.

Sanborn, D. E., Sanborn, C. J., Cimbolic, P., Niswander, G. D.: "Suicide and stress-related dermatoses." *Dis. Nerv. Syst.* **33**: 391-394 (1972). J21,824/72

Brooksbank, B. W. L., Brammall, M. A.,

Cunningham, A. E., Shaw, D. M., Camps, F. E.: "Estimation of corticosteroids in human cerebral cortex after death by suicide, accident, or disease." *Psychol. Med.* **2**: 56-65 (1972). G97,911/72

The cortisol content of the frontal cerebral cortex of healthy individuals who had committed suicide was as low or lower than that of control patients who died suddenly without antecedent illness. "It is concluded therefore that neither the presumed severe emotional stress preceding suicide nor depressive illness itself is associated with high levels of cortisol in the cerebral cortex." On the other hand, in patients who died from stressful somatic disease, brain cortisol was raised proportionately to the duration and severity of their physical illness.

Brooksbank, B. W. L., Brammall, M. A., Shaw, D. M.: "Estimation of cortisol, cortisone and corticosterone in cerebral cortex, hypothalamus and other regions of the human brain after natural death and after death by suicide." *Steroids Lipids Res.* **4**: 162-183 (1973). H82,485/73

Comparative studies on the cortisol, corticosterone and cortisone levels in various parts of the human brain after accidental death or suicide. "In 8 sudden-death control and 6 suicide brains, the concentration of cortisol and of corticosterone was higher in the controls, in both cerebral cortex and in hypothalamus. In most specimens, the levels were higher in the hypothalamus, but there was no difference between controls and suicides in the relationship between the two steroids or between the two brain regions. Cortisone levels were often too low to be measurable, but appeared to parallel the level of cortisol." It is assumed that suicide is associated with stress.

Kreitman, N., Chowdhury, N.: "Distress behaviour: a study of selected Samaritan clients and parasuicides ('attempted suicide' patients). Part I: General aspects." *Br. J. Psychiatry* **123**: 1-8 (1973). J19,559/73

Krieger, G.: "The plasma level of cortisol as a predictor of suicide." *Dis. Nerv. Syst.* **35**: 237-240 (1974). J12,780/74

High plasma cortisol levels are frequently noted in anxious and depressed patients who

subsequently commit suicide, and may be used as a warning sign.

→**Cardiovascular System** (See also Diseases of Adaptation). Morris, D. P.: "Blood pressure and pulse changes in normal individuals under emotional stress; their relationship to emotional instability." *Psychosom. Med.* **3**: 389-398 (1941). B26,186/41

In student nurses undergoing examinations and student pilots performing different flying exercises for the first time, a rise in blood pressure was quite constant, while pulse rate was more variable and sometimes actually decreased during the stress. Pallor, tremor, flushing, excessive sweating, restlessness and apprehensive facial expression were also studied as possible indicators of stress but the results proved more difficult to interpret.

Loftus, T. A., Gold, H., Diethelm, O.: "Cardiac changes in the presence of intense emotion." *Am. J. Psychiatry* **101**: 697-698 (1945). B26,677/45

In man, intense emotional arousal and anxiety evoke ECG changes but these appear to be largely independent of the type of emotion experienced.

Funkenstein, D. H., King, S. H., Drolette, M.: "The direction of anger during a laboratory stress-inducing situation." *Psychosom. Med.* **16**: 404-413 (1954).

C1,759/54

When exposed to stress-inducing "problem situations" in which failure is rudely criticized, some individuals react with anger, others with anxiety. Each of these response types is associated with different effects upon blood pressure and ballistocardiographic measures.

Jost, H., Epstein, L. J.: "The Rorschach as a physiological stress." *J. Clin. Psychol.* **12**: 259-263 (1956). C17,467/56

The Rorschach test is a stressor as indicated by its effect on heart rate, blood pressure and GSR in young adults.

Fencl, V., Hejl, Z., Jirka, J., Madlaousek, J., Brod, J.: "Changes of blood flow in forearm muscle and skin during an acute emotional stress (mental arithmetic)." *Clin. Sci.* **18**: 491-498 (1959). C81,538/59

Brod, J., Fencl, V., Hejl, Z., Jirka, J.: "Circulatory changes underlying blood pressure elevation during acute emotional stress (mental arithmetic) in normotensive and hypertensive subjects." *Clin. Sci.* **18**: 269-279 (1959). C85,146/59

Extensive studies on man led to the conclusion that "the detailed haemodynamic response to emotional stress resembles that occurring on strenuous muscular exercise. It is suggested that it is probably the same reaction, activated by situations which might necessitate strenuous muscular action" (33 refs.).

Thackray, R. I., Pearson, D. W.: "The effects of cognitive appraisal of stress on heart rate and task performance." *Federal Aviation Administration, Aviation Med. pamphlet*, p. 6. Washington, D.C., 1968. G65,881/68

Studies on tachycardia produced by the fear of an electric shock, which might or might not be given depending upon performance on a pursuit rotor. Male undergraduates were divided into those who did and those who did not fear shocks. "High fear of shock subjects revealed significantly greater heart rate acceleration and performance impairment, but only under the condition in which the subjects were told that receipt of shock would be contingent on prior performance level."

Jones, M. T., Bridges, P. K., Leák, D.: "Relationship between the cardiovascular and sympathetic responses to the psychological stress of an examination." *Clin. Sci.* **35**: 73-79 (1968). G60,678/68

Rashman, S. M.: "Changes in the body functions in students under the effect of examinations." *Fiziol. Zh. (Kiev)* **17** No. 1: 97-100 (1971) (Ukrainian). J20,490/71

Students taking examinations show typical stress ECGs.

Doctoral thesis showing that in man, different modes of inducing anxiety increase GSR and pulse rate while decreasing performance.

Dreyfuss, F.: "Coagulation time of the blood, level of blood eosinophils and thrombocytes under emotional stress." *J. Psychosom. Res.* **1**: 252-257 (1956). C26,923/56

In medical students during final examinations, eosinopenia and accelerated *blood clotting* were not accompanied by significant variations in platelet count.

Johnsson, T., Lavender, J. F., Marsh, J. T.: "The influence of avoidance-learning stress on resistance to Coxsackie virus in mice" (abstracted). *Fed. Proc.* **18**: 575 (1959). C66,433/59

Pruitt, R. D.: "Death as an expression of functional disease." *Mayo Clin. Proc.* **49**: 627-663 (1974). H93,314/74

General review in which death, including "Voodoo Death" and death from fright (as, for example, among canaries exposed to but beyond the reach of a leopard) is explained by nervous reflexes, especially those regulating heartbeat (excellent bibliography).

+Genetics. Kracht, J. Spaethe, M.: "Ueber Wechselbeziehungen zwischen Schilddrüse und Nebennierenrinde. II. Mitteilg. Untersuchungen über den 'Hypophysenhemmstoff' p-Oxypropiophenon" (Interrelation between the thyroid and the adrenal cortex. II. Report. Studies on the "hypophysial inhibitor" p-oxypropiophenone). *Virchows Arch. [Pathol. Anat.]* **323**: 629-644 (1953).

B85,143/53

Wild rabbits respond to frightening stimuli not only with adrenocortical enlargement, but also with a marked discharge of TTH which causes thyroid hypertrophy. This peculiar response can be prevented by hypophysectomy or methylthiouracil.

Kracht, J., Spaethe, M.: "Ueber Wechselbeziehungen zwischen Schilddrüse und Nebennierenrinde. III. Mitt. Die thyreotrope Belastungsreaktion" (Interrelation between the thyroid and the adrenal cortex. III. Report. The thyrotropic stress reaction). *Virchows Arch. [Pathol. Anat.]* **324**: 83-109 (1953). B87,399/53

In wild rabbits, fear produces an acute discharge of TTH, often with an actual inhibition of ACTH secretion. "The symptomatology and the cause of fear thyrotoxicosis can be classified in terms of the phases of the alarm reaction, resistance and exhaustion (Selye). Increased thyrotropic function causes inhibition of ACTH secretion."

Bridges, P. K., Jones, M. T.: "Relationship of personality and physique to plasma cortisol levels in response to anxiety." *J.*

Neurol. Neurosurg. Psychiatry **31**: 57-60
(1968). G56,652/68

During academic examinations, the plasma level of cortisol in medical students rose considerably as a consequence of anxiety. The degree of response was correlated with both the physical and mental constitution of the candidates. "It is suggested that there is an intrinsic sensitivity in anxiety responses to psychological stress that has an important association with physique."

Moore, T.: "Stress in normal childhood." *Hum. Relat.* **22** No. 3: 235-250 (1969).

E67,152/69

Effect of psychologic stressors upon the mentality of children, including neonates.

Bridges, P. K., Jones, M. T., Leak, D.: "A taxonomic study of physiological responses to a psychological stress." *J. Neurol. Neurosurg. Psychiatry* **33**: 180-187 (1970).

J11,245/70

Taxonomic studies were performed in students to establish the relationship between the stressor effect of examinations (plasma cortisol, catecholamine excretion, blood pressure, and so on) and constitutional factors (body build, personality types).

Hodges, W. F., Felling, J. P.: "Types of stressful situations and their relation to trait anxiety and sex." *J. Cons. Clin. Psychol.* **34**: 333-337 (1970).

J20,483/70

+**Restraint.** Mikhail, A. A.: "Relationship of conditioned anxiety to stomach ulceration and acidity in rats." *J. Comp. Physiol. Psychol.* **68**: 623-626 (1969). G68,624/69

In rats, conditioned anxiety did not aggravate the production of stress ulcers by restraint.

Caul, W. F., Buchanan, D. C., Hays, R. C.: "Effects of unpredictability of shock on incidence of gastric lesions and heart rate in immobilized rats." *Physiol. Behav.* **8**: 669-672 (1972). G91,264/72

In restraint-conditioned rats, unpredictable electric shocks produced a higher incidence of gastric ulcers than did predictable shocks.

+**Electroshock.** Taylor, R. H., Gross, M., Ruby, I. J.: "Nonconvulsive electrostimulation and the pituitary-adrenocortical system." *J. Nerv. Ment. Dis.* **114**: 377-383 (1951). J8,693/51

Both convulsive and nonconvulsive electrostimulation produced marked eosinopenia even in schizophrenic patients, although earlier investigators claimed that these usually failed to show such a response. Pentothal anesthesia did not prevent this eosinopenia, and it was therefore attributed not to stress but to a direct action of electric current on the hypothalamus. The literature on the effect of electroshock upon blood eosinophils is reviewed (17 refs.).

Vogel, J. R., Haubrich, D. R.: "Chronic administration of electroconvulsive shock effects on mouse-killing activity and brain monoamines in rats." *Physiol. Behav.* **11**: 725-728 (1973). J7,248/73

In rats, mouse-killing activity is blocked by chronic electroconvulsive shocks as well as by antidepressive drugs. At the same time, brain NEP concentrations rise (23 refs.).

+**Drugs, Hormones.** Steinberg, H.: "Effects of nitrous oxide on reactions to stress." *Bull. Br. Psychol. Soc.* **24**: 12 (1954).

J13,306/54

In men under the stress of being asked to solve insoluble problems, inhalation of small amounts of nitrous oxide (sufficient to cause euphoria) reduced stress. [The brief abstract gives no details about how this was measured (H.S.).]

Russell, R. W., Steinberg, H.: "Effects of nitrous oxide on reactions to 'stress'." *Q. J. Exp. Psychol.* **7**: 67-73 (1955).

D81,503/55

"The present investigation using insoluble and soluble problems has demonstrated that both nitrous oxide and exposure to stress impair learning; but that, when subjects are exposed to stress while under the influence of the drug, the effects of the stress on subsequent learning are abolished."

Frankenhaeuser, M., Post, B.: "Catecholamine excretion during mental work as modified by centrally acting drugs." *Acta Physiol. Scand.* **55**: 74-81 (1962). D35,589/62

In medical students the stress of various "intellectual tests" increased urinary EP excretion, and this change could be suppressed by methamphetamine and pentothenal. It appears that "urinary excretion of adrenaline provides a sensitive measure of reactions to mental stress, and that centrally acting drugs may influence adrenaline excretion during mental work."

Frankenhaeuser, M., Kareby, S.: "Effect of meprobamate on catecholamine excretion during mental stress." *Percept. Mot. Skills* **15**: 571-577 (1962). E30,225/62

In students, the psychogenic stress of problem solving (and, to a lesser extent, even the anticipation of it) caused an increase in EP and NEP excretion. After simultaneous administration of meprobamate, EP output rose but NEP decreased during stress. Thus "meprobamate in moderate doses counteracted the increase in the catecholamine response of normal individuals subjected to mental stress in a laboratory situation."

Baumann, R.: "Die Bedeutung des Stress für die Regulation des Kohlenhydratstoffwechsels und den Insulineffekt" (The importance of stress in regulating carbohydrate metabolism and the effects of insulin). *Zentralbl. Chir.* **92**: 1324-1334 (1967).

F91,158/67

In rats, psychogenic stress increases blood sugar and makes insulin hypoglycemia and the associated shock phenomena more intense and acute, although the latter are not

directly dependent upon the dose of insulin or the blood sugar level.

+Varia. Colehour, J. K., Graybiel, A.: "Excretion of 17-hydroxycorticosteroids, catechol amines, and uropepsin in the urine of normal persons and deaf subjects with bilateral vestibular defects following acrobatic flight stress." *Aerospace Med.* **35**: 370-373 (1964). G11,705/64

Deaf persons with *vestibular defects* who accompanied experienced pilots on acrobatic flights failed to show the usual increase in corticoids and catecholamines, presumably because their appropriate sensory organs in the inner ear were not functional.

Patton, G. W. R.: "Combined autonomic effects of concurrently-applied stressors." *Psychophysiology* **6**: 707-715 (1970).

H47,514/70

In U.S. soldiers, the stress effects (pulse rate, blood pressure, skin conductance) of solving anagrams and exposure to *cold* were greater than when each stressor was applied alone.

Public Speaking

Public speaking is extraordinarily stressful for many people and tends to cause a curious mixture of distress and eustress, depending largely upon the response of the audience. In this respect, success is often most exhilarating, whereas evidence of an adverse response (facial expressions of boredom, enmity and disagreement on the part of the audience, or the departure of many people before the end of the speech) usually causes considerable distress. But often both positive and negative responses elicit the characteristics of stress, such as evidence of enhanced adrenergic activity, acceleration of the heart rate (up to 180 per minute), a rise in blood pressure, increases in plasma NEP and FFA, excessive mental arousal and so on.

Most of these manifestations can be suppressed by β -adrenergic blocking agents (for example, oxprenolol) without noticeably interfering with the ability of the speaker to express his thoughts, although a certain amount of arousal is indispensable for optimal efficiency.

Every public speaker has experienced the fact that manifestations of approval by the public improve his performance, whereas the reverse is true if the speech is badly received. Under these conditions, many people, especially beginners, become virtually inarticulate. Experience usually improves the performance even of poor speakers, particularly during question and answer periods. Since, during delivery of many speeches, they have met most of the problems likely to arise, an appropriate statement becomes virtually a reflex response requiring no embarrassing delays and hesitations.

Public Speaking

Somerville, W.: "Emotions, catecholamines and coronary heart disease." *Adv. Cardiol.* **8**: 162-173 (1973). J16,987/73

A statistical study shows that "certain experienced motor-car drivers with a history of coronary heart disease when driving in busy traffic develop angina, sinus tachycardia, ectopic beats and various arrhythmias. Healthy racing drivers, stimulated by the emotions of competition and danger, develop high-grade sinus tachycardia, raised plasma catecholamines and free fatty acids immediately before and after a race. Public speaking induces in normal persons similar changes in heart rate and rhythm and elevations in plasma catecholamines and free fatty acids. In both drivers and public speakers, triglycerides show a peak elevation 1-2 h after the event. Oxprenolol inhibits the increase in heart rate, plasma catecholamines, free fatty acids and triglycerides."

MacLeod, R. D. M.: "Unaccustomed speakers." *Lancet* August 25, 1973, pp. 440-441. J19,608/73

Although β -adrenergic blockade by oxprenolol has been recommended to alleviate

the unpleasant symptoms, especially the cardiovascular manifestations in anxious public speakers. the author feels that a more realistic aim would be "to encourage adaptation to stress rather than attempting to shield individuals throughout their lives from the problems of living."

Taggart, P., Carruthers, M., Somerville, W.: "Electrocardiogram, plasma catecholamines and lipids, and their modification by oxprenolol when speaking before an audience." *Lancet* August 18, 1973, pp. 341-346.

H74,091/73

In normal subjects and patients with coronary heart disease, speaking before an audience caused tachycardia (up to 180 per minute) and increases in plasma catecholamine and FFA levels. Ectopic heart beats were noted in about 25 percent of the subjects. A single dose of the β -adrenergic blocker, oxprenolol, suppressed most of the cardiac anomalies in both the normal and the coronary subjects, although plasma NEP levels were not significantly affected. Presumably, "emotional challenges may produce conspicuous cardiovascular effects, especially in susceptible persons. It is suggested that β -blockade could be used to alleviate the unpleasant symptoms associated with speaking before an audience."

Vaisrub, S.: "Unaccustomed as I am to..." *J.A.M.A.* **226**: 1226-1227 (1973).

H78,576/73

Report on various stress indices (tachycardia, rise in plasma catecholamine and FFA concentrations) in people immediately after they address an audience. These responses can be prevented by prophylactic administration of β -adrenergic-blocking agents.

Sleep Deprivation

The unpleasant effects of sleep deprivation are so well known, especially to insomniacs, that they hardly require any detailed discussion here. Yet, on the basis of observations on four young men deprived of sleep for 120 hours, in whom neither corticoid nor catecholamine production appeared to be altered, it was "concluded that although sleep deprivation is stressful it does not operate through Selye's model." In a more extensive study on 600 subjects, 112 hours of sleep deprivation elicited characteristic EEG changes, irritability, loss of memory, hallucinations, and occasional symptoms resembling acute schizophrenia, not unlike those seen in sensory deprivation. However, blood sugar hemoglobin, white cell count and various indicators of corticoid production were barely affected. Perhaps sleep deprivation, isolation and

monotony are not potent stressors in that they make no great demands on any function and, though unpleasant, they act somewhat like leisure or TM.

In soldiers performing on a shooting range for seventy-five hours without sleep, catecholamine excretion was increased and the amplitudes of the circadian rhythm of EP excretion were accentuated, while NEP elimination curves became more irregular. However, in these studies, it is difficult to distinguish pure sleep deprivation from the associated psychomotor performance as a possible stressor.

In young men, lack of sleep for 120 hours deactivated the CNS, as indicated by EEG α -waves, but produced a mixed pattern of deactivation of the ANS with a gradual return to the predeprivation level toward the fifth day. This coincided with increased 17-OHCS excretion. Despite such a rise in corticoid elimination, it was concluded that prolonged sleep loss "did not produce a Selye-type generalized stress reaction."

Yet other studies on university students showed that sleep deprivation can initially raise pulse rate and GSR, with a secondary decline during a later phase. Recent investigations indicate that even moderate sleep loss increases plasma cortisol levels in man; indeed, 11-OHCS excretion has been claimed to be inversely correlated with the amount of sleep during an average night.

These apparently contradictory results show that the stressor effect of sleep deprivation is still far from clearly established. Perhaps further studies should give more attention to the all-important conditioning factors, especially to the type of activity performed during sleep deprivation. Furthermore, it may be worth examining the possibility that sleep deprivation (like the "pseudohypophysectomy" of prolonged undernutrition) could specifically interfere with the hypothalamus pituitary-adrenocortical axis, for example, by inhibiting the function of the neurotransmitter mechanisms.

Sleep Deprivation

(See also our earlier stress monographs, p. xiii)

Tyler, D. B., Marx, W., Goodman, J.: "Effect of prolonged wakefulness on the urinary excretion of 17-ketosteroids." *Proc. Soc. Exp. Biol. Med.* **62**: 38-40 (1946).

B1,301/46

In man, 112 hours of forced wakefulness failed to alter the urinary excretion of 17-KS (taken as an indicator of corticoid production). These observations on twenty-four-hour samples contradict earlier data based on comparatively short periods of stress.

Tyler, D. B.: "The 'fatigue' of prolonged wakefulness." *Fed. Proc.* **6**: 218 (1947).

B26,692/47

In six hundred subjects, sleep deprivation for up to 112 hours caused characteristic EEG changes, irritability, loss of memory, hallucinations and occasional symptoms resembling acute schizophrenia. The ability to maintain sustained effort and performance

was also diminished. However, "blood sugar, hemoglobin, red and white cell count, body weight, and body temperature show little variation from the normal. The excretion of 17-ketosteroids, total nitrogen and creatinine, and the level of adrenal-like substances in the blood are little affected."

Murawski, B. J., Crabbé, J.: "Effect of sleep deprivation on plasma 17-hydroxycorticosteroids." *J. Appl. Physiol.* **15**: 280-282 (1960). C83,739/60

Hasselman, M., Schaff, G., Metz, B.: "Influences respectives du travail, de la température ambiante et de la privation de sommeil sur l'excrétion urinaire de catécholamines chez l'homme normal" (Influence of work, ambient temperature and sleep deprivation on urinary catecholamine secretion in normal men). *C. R. Soc. Biol. (Paris)* **154**: 197 (1960). C88,413/60

In people performing multiple-choice psychomotor muscular work, catecholamine excretion rose; this effect was particularly

pronounced following periods of sleep deprivation.

Gifford, S., Murawski, B. J.: "Minimal sleep deprivation alone and in small groups: Effects on ego-functioning and 24-hour body temperature and adrenocortical patterns." *Symposium on the Medical Aspects of Stress in the Military Climate*, pp. 157-185. Washington, D.C., 1964 (43 refs.). B45,972/64

Mandell, A. J., Sabbot, I. M., Mandell, M. P., Kollar, E. J.: "The stress responsive indole substance in sleep deprivation." *Arch. Gen. Psychiatry* **10**: 299-305 (1964).

G2,556/64

In man, sleep deprivation and other stressors as well as ACTH and functioning adrenocortical tumors produce in the urine a "stress responsive indole substance (SRIS)" whose physical and chemical characteristics are described, although it could not be definitely identified.

Edholm, O. G., Bacharach, A. L. (eds.): *The Physiology of Human Survival*, p. 581. New York and London: Academic Press, 1965. E6,283/65

A monograph on human reactions to various stressors such as heat, cold, anoxia, high altitudes, compression and decompression, nutritional damage, sleep deprivation, monotony, fatigue, emotional arousal and muscular exercise. Each chapter is written by a specialist in the corresponding field, and numerous references indicate the difference between specific defense mechanisms and the stressor effect of the agents used.

Luce, G. G., Segal, J.: *Sleep*, p. 335. New York: Coward-McCann, 1966. E1,208/66

Semipopular monograph on sleep, with sections on the effect of stress upon insomnia. An extensive bibliography lists both technical and popularized references on sleep.

Kollar, E. J., Slater, G. R., Palmer, J. O., Docter, R. F., Mandell, A. J.: "Stress in subjects undergoing sleep deprivation." *Psychosom. Med.* **28**: 101-113 (1966).

G39,265/66

In four young men deprived of sleep for 120 hours, "corticoid and psycho-physiologic measurements did not reveal an adrenosympathetic activation. Both subjects and observers concluded that although sleep deprivation is stressful it does not operate through Selye's model." Neither personal observations nor the literature have convinced the authors

that loss of sleep could produce psychoses (36 refs.).

Cartwright, R. D., Monroe, L. J., Palmer, C.: "Individual differences in response to REM deprivation." *Arch. Gen. Psychiatry* **16**: 297-303 (1967). J22,691/67

Fiorica, V., Higgins, E. A., Iampietro, P. F., Lategola, M. T., Davis, A. W.: "Physiological responses of men during sleep deprivation." *J. Appl. Physiol.* **24**: 167-176 (1968). G55,182/68

Metabolic studies and resistance to cold in man after eighty-four to eighty-six hours of sleep deprivation showed no very constant and significant deviations from the norm. Plasma catecholamines were increased during cold in both experimental and control subjects.

Solomon, G. F.: "Stress and antibody response in rats." *Int. Arch. Allergy Appl. Immunol.* **35**: 97-104 (1969). G64,541/69

"Overcrowding stress, but not the stress of apprehension-electric shock, administered for a week prior to immunization with a potent bacterial antigen, flagellin, and continued during the course of observation significantly reduced both primary and secondary antibody response in inbred male rats. The stress of remaining on a small platform (with rapid eye-movement sleep deprivation) or medium sized platform (without REM deprivation) over a pan of water significantly reduced primary but not secondary response" (31 refs.).

Kuhn, E., Brodan, V., Brodanová, M., Rysánek, K.: "Metabolic reflection of sleep deprivation." *Activ. Nerv. Sup. (Praha)* **11**: 165-174 (1969). J23,076/69

Polis, B. D., Polis, E., DeCani, J., Schwarz, H. P., Dreisbach, L.: "Effect of physical and psychic stress on phosphatidyl glycerol and related phospholipids." *Biochem. Med.* **2**: 286-312 (1969). G65,013/69

In rats exposed to ionizing radiation or "acceleration stress," the plasma concentration of phosphatidylglycerol was consistently increased. "Extension of the studies to humans stressed by acceleration to grayout, sleep deprivation, schizophrenia, combat, etc., revealed that all stresses were accompanied by significant increments in plasma phosphatidyl glycerol." In rats, hypophysectomy prevented the increase in phosphatidylglycerol induced by acceleration stress, but a

rise in the brain level of this compound remained even in the absence of the pituitary.

Fröberg, J., Karlsson, C. G., Levi, L., Lidberg, L., Seeman, K.: "Conditions of work and their influence on psychological and endocrine stress reactions." *Rep. Lab. Clin. Stress Res.* (Stockh.) No. 8: 1-19 (1969).

G69,180/69

In Swedish officers deprived of sleep for seventy-five hours and performing on an electronic shooting range or engaged in military staff work, NEP and EP excretion was increased, as were the erythrocyte sedimentation rate and the amount of protein-bound iodine, whereas serum iron was decreased. Some subjects developed ECG anomalies, particularly ST-T depression, and it took several days of rest for the ECG patterns to return toward normal. Stressors imitating situations in civilian life produced essentially similar changes proportional to their severity.

Fröberg, J., Karlsson, C. G., Levi, L., Lidberg, L., Seeman, K.: "Circadian rhythms in catecholamine excretion, psychomotor performance and ratings of stress and fatigue during a 75-hour vigil." *Studia Laboris et Salutis* No. 4 (1969).

G87,093/69

Observations on thirty-one men of different ages who were deprived of sleep for seventy-five hours. Considerable fatigue and a decline in motor performance developed with a rise in EP excretion. The highest rates occurred during early afternoon, the lowest during the night and early morning hours. The amplitude of the circadian rhythm in EP excretion was increased by sleep deprivation. NEP elimination curves were much less regular.

Mark, J., Heiner, L., Godin, Y.: "Le stress au cours de la privation expérimentale du sommeil paradoxal" (Stress during experimental deprivation of paradoxical sleep). *J. Physiol. (Paris)* **62** Supp. 1: 185 (1970).

Naitoh, P., Pasnau, R. O., Kollar, E. J.: "Psychophysiological changes after prolonged

deprivation of sleep." *Biol. Psychiatry* **3**: 309-320 (1971).

H73,911/71

In young adult males, "sleep loss of up to 120 hr. deactivated the central nervous system (CNS) as judged by EEG alpha time, but it produced a mixed pattern of deactivation of the ANS. Around the 'fifth day' of sleep loss, a yet-undefined adaptive mechanism was actuated, allowing a slow shift of the oral temperature as well as EEG alpha time toward the predeprivation level, coincident with increased secretion of 17-hydroxycorticosteroid. A simple notion of generalized activation and deactivation could not account for a complex bodily mechanism during sleep loss, and the vigil did not produce a Selye-type generalized stress reaction." Despite increased corticoid excretion, it is concluded that prolonged wakefulness cannot be regarded as a generalized Selye-type stressor: "it introduced a profound change in the subjects by actuating an adaptive mechanism which was only slowly stopped after more than three nights of recovery sleep."

Utting, J. E., Whitford, J. H. W.: "Assessment of premedicant drugs using measurements of plasma cortisol." *Br. J. Anaesth.* **44**: 43-46 (1972).

G88,755/72

Even moderate sleep deprivation increases plasma cortisol in man. Hence, normalization of plasma cortisol in preoperative patients may be due to the soporific rather than to the anxiolytic effect of drugs used for premedication.

Review on the stressor effects of shift work and sleep deprivation.

Kapen, S., Boyar, R. M., Finkelstein, J. W., Hellman, L., Weitzman, E. D.: "Effect of sleep-wake cycle reversal on luteinizing hormone secretory pattern in puberty." *J. Clin. Endocrinol. Metab.* **39**: 293-299 (1974).

H89,310/74

In pubertal children, plasma LH levels

rose during sleep at night or during the daytime. Plasma LH concentrations remained elevated during nocturnal waking but not during daytime waking, showing that sleep-wake reversal does not prevent increased LH secretion at night. "Therefore, it is unlikely that the stress associated with sleep deprivation or reversal of the sleep-wake patterns was responsible for the elevated nocturnal waking secretion of LH found in this study" (35 refs.).

Inoue, S., Nagasaki, H., Iriki, M.: "Total sleep deprivation and weight increases of the reproductive organs in male rats." *Endocrinol. Jap.* **21**: 283-286 (1974).

H92,991/74

Rats exposed to long-term sleep loss in a cage where they were forced to move continuously in order to avoid electric shocks experienced hypertrophy of the adrenals, testes, ventral prostates and seminal vesicles. "It is supposed that either the sleep deprivation *per se* or stressful conditions accompanied with the treatment caused a hypersecretion of hypophyseal and testicular hormones." [It is unusual for chronic stress to produce hypertrophy of the sex organs, and these observations appear to be incompatible with the pituitary-shift theory (H.S.).]

Matussek, N., Ackenheil, M., Athen, D., Beckmann, H., Benkert, O., Dittmer, T., Hippius, H., Loosen, P., Rüther, E., Scheller, M.: "Catecholamine metabolism under sleep deprivation therapy of improved and not improved depressed patients." *Pharmakopsychiatrie* **7**: 108-114 (1974). J12,520/74

Sleep deprivation is often but not invariably effective as a transitory treatment in certain types of depressed patients. Only in those showing definite improvement is NEP and VMA elimination increased.

Mendelson, W., Guthrie, R. D., Guynn, R., Harris, R. L., Wyatt, R. J.: "Rapid eye movement (REM) sleep deprivation, stress and intermediary metabolism." *J. Neurochem.* **22**: 1157-1159 (1974). J14,449/74

Rats divided into four groups show "a range of values for lactate, pyruvate and malate. With the baseline at the low end, the two stress control groups in the middle, and the REM sleep deprived group at the upper end, only the difference between the two extremes reaches statistical significance. One possible implication is that the changes in these three metabolites may be related to

both the 'stress' of the experimental condition and REM sleep deprivation, perhaps in a cumulative manner."

Fröberg, J. E.: "Circadian rhythms in catecholamine excretion, performance and selfratings." *Rep. Lab. Clin. Stress Res.* (Stockh.) **36**: 1-22 (1974). J17,328/74

Observations on man "have shown that adrenaline excretion, performance and subjective arousal are low during the night and high during the day even under conditions of sleep deprivation and regularly spaced meals and other activities. Both the physiological and the psychological arousal rhythms had crests in the small hours."

Palmlad, J., Cantell, K., Strander, H.,

Fröberg, J., Karlsson, C. G., Levi, L.: "Stressor exposure and human interferon production." *Rep. Lab. Clin. Stress Res.* (Stockh.) **35**: 1-8 (1974). J17,329/74

In women exposed to a seventy-seven-hour vigil and showing hormonal changes characteristic of stress, the ability of the blood cells to produce interferon following addition of Sendai virus to blood samples rose considerably.

Motivation

The stressor effect of motivation does not lend itself well to strict scientific analysis because of the innumerable conditioning factors that influence it and the many specific actions of the tasks selected as tests.

In an extensive study on 185 preparatory school boys, predominantly achievement-oriented and affiliation-oriented subjects were separated, and further subdivided into successful and unsuccessful individuals. Stress was appraised by autonomic reactions, including pulse rate, blood pressure, and GSR. Successful subjects were more easily aroused by minimally threatening conditions and less disturbed by severe stressors. Intrinsic motivation, the type of task, and the subject's past history of success and failure also influenced reactivity, but broad generalizations could not be made from this or similar studies.

The same difficulty arises in the interpretation of an investigation on a U.S. Navy underwater demolition team, in which a positive correlation was found between serum uric acid levels and subjective estimates of motivation. The serum cholesterol concentrations demonstrated a negative correlation with the intensity of motivation and pleasure in doing the work. The reverse was true for those who found the task unpleasant, and thus serum cholesterol values could not be said to correlate very consistently with these indicators of motivation.

Motivation

J11,126/56

Extensive review on ego involvement in psychogenic stress (173 refs.).

Vogel, W., Raymond, S., Lazarus, R. S.: "Intrinsic motivation and psychological stress." *J. Abnorm. Soc. Psychol.* 58: 225-233 (1959). J4,021/59

One hundred and eighty-five preparatory school boys were grouped on the basis of different tests as predominantly achievement-oriented or affiliation-oriented, each group being subdivided into successful and unsuccessful subjects. Stress was appraised by autonomic reactions including pulse rate, blood pressure and GSR. The induction of stress depended upon the relationship between the motive pattern and the type of stressor used. "The relative effect of stress on a sensory-motor task was facilitative, while on a conceptual task it produced impairment. Successful subjects were more easily aroused by minimally threatening conditions than unsuccessful subjects, and less disturbed by more severe stressor conditions." Intrinsic motivation, the type of task and the subject's history of success or failure are basic components in psychogenic stress.

Rahe, R. H., Rubin, R. T., Gunderson, E. K. E.: "Measures of subjects' motivation and affect correlated with their serum uric acid, cholesterol, and cortisol." *Arch. Gen. Psychiatry* 26: 357-359 (1972).

G90,674/72

Among trainees of a U.S. Navy underwater demolition team, "predominantly positive correlations were seen between the subjects' serum uric acid levels and their estimates of their own motivation. Their serum cholesterol concentrations demonstrated consistently negative correlations with their motivational and pleasant affect scores. Highest correlations were positive ones found between the subjects' serum cholesterol levels and their unpleasant affect scores. Serum cortisol correlations with the three psychological criteria demonstrated wide variability around a zero correlation baseline."

Cognition

Most of the evidence on the relationship between stress and cognition is discussed with other functional changes induced by stressors, under the special headings of Performance and Learning Ability. However, learning itself can act as a stressor.

Although the literature on the subject is very limited, it suggests that there is a positive relationship between pituitary-adrenocortical activity and facilitated avoidance learning, which appears to be a function of age. Furthermore, cardiac rhythm and urinary catecholamine excretion increase in men under the influence of intense mental work, while even mere calculating may suffice to produce eosinopenia in women. The performance of arithmetic tasks has also been shown to cause elevated levels of plasma corticoids, FFA, and blood pressure, as well as changes in blood electrolytes, proteins and cholesterol.

Cognition

Haggard, E. A.: "Experimental studies in affective processes: I. Some effects of cognitive structure and active participation on certain autonomic reactions during and following experimentally induced stress." *J. Exp. Psychol.* **33**: 257-284 (1943).

B33,896/43

Experiments on man using a test consisting of three periods. "I, the conditioning or stressful session, during which the S's were asked to give chained associations to each of 42 stimulus words. They were always (and only) shocked between 10 and 12 sec. after the stimulus word *sword*, which recurred five times during the list; II, the therapy session, in which one of three experimental procedures was employed to alleviate the general disturbance and extinguish the specific reactions initiated during the first session; and finally, III, a test period to measure the relative effectiveness of the therapies." A strong electric shock was employed as the stressor, and GSR was used as the principal indicator of autonomic activity. "In general, those individuals who knew most about the conditions involved in the situation and who took an active attitude or role in facing this experience consistently showed less disturbance on all measures of autonomic reactivity during the stressful and therapy sessions" (87 refs.).

Ulrych, M.: "Changes of general haemodynamics during stressful mental arithmetic and non-stressing quiet conversation and modification of the latter by beta-adrenergic blockade." *Clin. Sci.* **36**: 453-461 (1969).

G67,814/69

Hemodynamic studies on forty-seven subjects showed that "both stressful mental arithmetic and quiet speaking resulted in similar increases in mean arterial pressure (12.7% and 13.8%) and cardiac output (22.6% and 23.6%) and therefore in similar changes in total peripheral vascular resistance. In the case of stressful mental arithmetic the increased cardiac output was exclusively due to an increase in heart rate (28.8%) but during quiet conversation both heart rate (14.4%) and stroke volume (8.3%) contributed to this rise." The considerable hemodynamic changes caused even by quiet conversation are apparently due to activation, since they can be prevented by β -adrenergic blockade.

J11,624/74

"Older animals acquired the conditioned avoidance response (CAR) faster and required a longer time to extinguish, than the younger animals. The enhanced CAR performance of the older animals could not be attributed to an altered pain threshold but was correlated with a significantly higher plasma corticosterone response to ether-stress. The data are interpreted as being consistent with the notion of a positive relationship between pituitary-adrenal activity and facilitated avoidance learning."

Friedman, M., Byers, S. O., Diamant, J., Rosenman, R. H.: "Plasma catecholamine response of coronary-prone subjects (Type A) to a specific challenge." *Metabolism* **24**: 205-210 (1975).

H98,918/75

In a nonphysical competitive struggle (puzzle solving), the plasma NEP content of type A persons rises 30 percent above that of type B individuals, whereas plasma EP remains essentially unchanged in both groups.

Fighting, Anger, Hate

Actual fighting, anger, aggressiveness and hate occur so often in association that it would be practically impossible to isolate each of them in a stress reaction. Many pertinent data in relation to the special case of military activities will be found in the section, Combat. Most of the relevant publications deal with the psychologic consequences of aggressive behavior, but there is considerable evidence to show that combativeness also elicits other manifestations of the classic stress syndrome. For example, voles kept in a cage viciously attack any stranger of the same species introduced among them. This leads to adrenal enlargement, thymic atrophy and other characteristic manifestations of the alarm reaction. Curiously, instead of the usual splenic atrophy in these animals, the spleen enlarges after fighting, perhaps because of secondary infections.

In rats, fighting causes adrenal enlargement and other characteristic signs of stress. In isolated male mice exposed to trained fighters several times a day, adrenal hypertrophy is associated with a rise in plasma corticosterone, whereas the seminal vesicles decrease in size, indicating diminished testicular function. Adrenal hyperactivity is particularly pronounced in mice that have previously experienced defeat, presumably because they are more frightened than are usually victorious animals.

The rate of brain catecholamine synthesis is lower in isolated than in grouped mice, but fighting rapidly accelerates the synthesis of both catecholamines and 5-HT in the brain. Deposition of cortisol crystals into the ME of rats did not influence electro-shock-induced fighting behavior. Yet, immediately after the last fight, the plasma corticosterone levels and adrenal weight indicated complete suppression of ACTH activity in the animals.

Much research has also been done on human aggression, particularly in the socio-political context. Among aggressive stressor agents, special attention has been given to anti-Semitism and other types of common race hatred, destructive student protests, anger towards traditionally, though irrationally, selected targets (scapegoats), and various movements to change society by violence.

Fighting, Anger, Hate

(See also our earlier stress monographs, p. xiii)

Clarke, J. R.: "The effect of fighting on the adrenals, thymus and spleen of the vole (*Microtus agrestis*)."*J. Endocrinol.* 9: 114-126 (1953). B77,639/53

Voles (*Microtus agrestis*) kept in a cage viciously attack any strangers of the same species introduced among them. The fighting results in adrenal enlargement and thymic atrophy characteristic of the alarm reaction, but instead of the usual splenic atrophy there is hypertrophy—perhaps due to secondary infection.

Funkenstein, D. H., King, S. H., Drolette, M.: "The direction of anger during a labora-

tory stress-inducing situation."*Psychosom. Med.* 16: 404-413 (1954).

C1,759/54

When exposed to stress-inducing "problem situations" in which failure is rudely criticized, some individuals react with anger, others with anxiety. Each of these response types is associated with different effects upon blood pressure and ballistocardiographic measures.

Barnett, S. A.: "Physiological effects of 'social stress' in wild rats—I. The adrenal cortex."*J. Psychosom. Res.* 3: 1-11 (1958).

J11,151/58

In wild male rats kept in groups, fighting produces enlargement of the adrenal, and there is occasional sudden death unrelated to wounds. "It may have resulted from dis-

turbed carbohydrate metabolism or from 'vagal syncope'."

Lemonde, P.: "Influence of fighting on leukemia in mice." *Proc. Soc. Exp. Biol. Med.* **102**: 292-295 (1959). C77,947/59

In leukemic strains of mice, fighting among males tends to delay the development of the disease, probably through the stress-induced discharge of ACTH and corticosterone.

Bronson, F. H., Eleftheriou, B. E.: "Chronic physiological effects of fighting in mice." *Gen. Comp. Endocrinol.* **4**: 9-14 (1964). F7,501/64

When isolated male mice were exposed to trained fighters several times a day, the adrenal weight and plasma corticosterone levels rose, whereas seminal vesicle weight decreased. Adrenal corticosterone concentrations paralleled the increase in adrenal weight.

Bronson, F. H., Eleftheriou, B. E.: "Adrenal response to fighting in mice: separation of physical and psychological causes." *Science* **147**: 627-628 (1965). F31,060/65

The plasma concentration of free corticosterone in mice exposed to the presence of a trained fighter is much greater if they have previously experienced defeat under similar conditions. The change is of essentially the same magnitude as in actual defeat. Apparently, the psychologic stress is more important than the physical damage of bites.

Thorne, F. C.: "Differing reactions of friendly and fear-biting dogs to severe stress." *J. Clin. Psychol.* **24**: 181-184 (1968). J23,708/68

Sigg, E. B.: "Relationship of aggressive behaviour to adrenal and gonadal function in male mice." In: Garattini, S. and Sigg, E. B., *Aggressive Behaviour*, pp. 143-149. Amsterdam: Excerpta Medica Foundation, 1969.

J10,865/69

The aggressive behavior of isolated mice was studied by extirpation of various endocrine glands and treatment with diverse hormones. It is concluded that "the male gonadal hormones are critically involved in this response whereas other endocrine changes (adreno-cortical, adreno-medullary and thyroid) may be contributory and consequential."

Fischer, D., Rule, B. G.: "Anti-Semitism, stress, and anchor effects on interpersonal

judgements." In: Presse, A. W. and Zubeck, J. P., *Readings in General Psychology: Canadian Contributions*, pp. 343-346. Toronto: McClelland and Stewart, 1970. E8,858/70

Purely psychologic studies on the effect of stress upon interpersonal judgments in subjects with varying degrees of anti-Semitism.

Parker, R. S.: "Anger, identification, and irrational target selection." In: Parker, R. S., *The Emotional Stress of War, Violence, and Peace*, pp. 12-70. Pittsburgh, Pa.: Stanwix House, 1972. E10,441/72

Hostility is regarded as a defensive adaptive response accompanied by anger and often expressed toward irrationally selected targets. The term stress is used in its broadest sense only.

Riscalla, L. M.: "The violence of non-violence. A barrier to enlightenment." In: Parker, R. S., *The Emotional Stress of War, Violence, and Peace*, pp. 128-132. Pittsburgh, Pa.: Stanwix House, 1972. E10,443/72

General discussion of demonstrations, student protests and other efforts to change society. The term stress is used essentially as a synonym for difficulty, and not in its medical connotation.

Hucklebridge, F. H., Nowell, N. W., Dilks, R. A.: "Plasma catecholamine response to fighting in the male albino mouse." *Behav. Biol.* **8**: 785-800 (1973). H92,272/73

"Mice which fought victories showed no evidence of an increase in plasma catecholamines, whereas plasma epinephrine, and to a lesser extent, norepinephrine were elevated in defeated mice and this response tended to be greater in mice which fought back when attacked. Attack by a trained fighter mouse was found to be a particularly effective stimulus for the release of epinephrine from the adrenal medulla."

Modigh, K.: "Effects of isolation and fighting in mice on the rate of synthesis of noradrenaline, dopamine and 5-hydroxytryptamine in the brain." *Psychopharmacologia* **33**: 1-17 (1973). J7,891/73

The rate of brain catecholamine synthesis is lower in isolated than in grouped mice and intense fighting rapidly accelerates the synthesis of both catecholamines and 5-HT in the brain.

Erskine, M. S., Levine, S.: "Suppression of pituitary-adrenal activity and shock-induced fighting in rats." *Physiol. Behav.* **11**: 787-790 (1973). J8,675/73

Deposition of cortisol acetate crystals into the ME of the hypothalamus did not influence the shock-induced fighting behavior of rats. Yet, immediately following the last fighting session, plasma corticosterone levels and adrenal weight showed complete suppression of pituitary-adrenal activity in the implanted group. Apparently, aggressive behavior is not mediated through ACTH and corticoids. The previously reported suppression by cortisol of muricidal behavior in rats could have been due to inhibition of ACTH secretion.

Allikmets, L. H.: "Cholinergic mechanisms in aggressive behaviour." *Med. Biol.* **52**: 19-30 (1974). J14,512/74

A review on brain 5-HT and catecholaminergic systems in aggressive behavior. It is suggested that the cholinergic trigger mechanism of aggressive behavior depends

on brain 5-HT and catecholaminergic processes (75 refs.).

Hucklebridge, F. H., Nowell, N. W.: "Plasma catecholamine response to physical and psychological aspects of fighting in mice." *Physiol. Behav.* **13**: 35-40 (1974).

J14,548/74

Plasma EP and, to a lesser degree, NEP levels were elevated in mice attacked daily by a trained fighter. The mere presence of the attacker caused no such change, but plasma corticosterone levels were raised. "It is suggested that, unlike adrenal corticosterone release which is induced by a relatively non specific state of hyperalertness or arousal, adrenomedullary epinephrine release is stimulated only under specific circumstances which, for the mice in the present experiment, were not met by a 'psychological' stimulus" (32 refs.).

Sensory Deprivation, Boredom, Monotony

The study of sensory deprivation illustrates the difficulties encountered in any attempt to interpret the stress concept correctly, that is, in accordance with its contemporary definition as the nonspecific reaction of the body to any demand: At first sight, it would appear that complete rest in the virtual absence of any external stimulus, psychic or somatic, would represent the state closest to total freedom from stress. This view is definitely incorrect.

Many experiments have shown that maximal sensory deprivation--when the subject lies quietly in a most comfortably cushioned bed, every effort being made to protect him against sound, temperature variations, air pollutants, physical or mental work, and all other stimuli that may make a "demand" upon his adaptive mechanisms--hardly provides protection against stress. Actually, under such conditions, the subject experiences "an intense desire for extrinsic sensory stimuli and bodily motion, increased suggestibility, impairment of organized thinking, oppression and depression, and, in extreme cases, hallucinations, delusions and confusion." Living beings are constructed for work, and if they have no outlet for their pent-up energy they must make extreme efforts at adaptation to this unphysiologic state of inactivity which has been named "deprivation stress" and which has been incorporated into the G.A.S. concept by Galdston.

Normal function of the brain depends on constant arousal generated in the reticular formation by continuous sensory input. Thus, hallucinations, which may cause accidents, have been noted in pilots, astronauts and long-distance truck drivers, the monotony of whose work presumably acts as a form of sensory deprivation.

Several excellent chambers have been described for sensory deprivation experiments, and the psychic manifestations of more or less prolonged residence in them have been carefully recorded; however, up to now, little is known about the associated somatic indicators, such as hormonal responses.

Although virtually complete sensory deprivation for prolonged periods is rare in daily life, a decrease in sensory input below the normal level is a common cause of boredom. It will undoubtedly represent a major pathogen, not only in astronauts on long voyages, but in all those whose work becomes increasingly monotonous as mass-production techniques develop.

Separation of infants from their mothers, and all types of relocation of people into strange environments which leave few possibilities for interpersonal contacts, are very common forms of sensory deprivation; they may become major factors in psychosomatic disease.

In infant rhesus monkeys, catecholamine synthesis is stimulated by mother-infant separation, and this process is neurally mediated.

Studies on female undergraduates showed that even ninety minutes of total isolation is stressful, as indicated by the rise in GSR. In children, prolonged emotional deprivation caused a kind of "hypopituitarism" with diminished ACTH and STH secretion, which was abolished by return to a normal environment. Undoubtedly, growth is inhibited, but according to another investigation, fasting serum STH is usually increased in emotionally deprived children, while the STH and ACTH responses to hypoglycemia are diminished.

In policemen, both understimulation and overstimulation enhanced NEP release. Subjects excreting more EP performed better during understimulation, whereas those with less EP output were more efficient during overstimulation.

1062-1063 (1955). C9,602/55

In healthy male volunteers, long periods of perceptual deprivation failed to cause any significant increase in 11-OHCS excretion. "As far as our data go, it appears that under these circumstances the adrenal cortex is not activated to a greater degree than it is by the minor exigencies of everyday life."

Heron, W.: "The pathology of boredom." *Sci. Am.* 196: 52-56 (1957). B28,802/57

Semipopular description of the experiments of D. O. Hebb and his group on sensory deprivation in specially constructed chambers. Subjects developed various types of hallucinations and became unable to concentrate on any particular topic. "The most striking finding was that when subjects emerged after several days of isolation, the whole room appeared to be in motion. In addition there was a tendency for surfaces to appear curved, and for objects to appear to be changing their size and shape. Asked to match a disk that was handed to them to one in a row of disks of various sizes 12 feet away, the subjects consistently chose a larger disk than did control subjects." Recent studies indicate that normal function

of the brain requires constant arousal generated in the reticular formation which in turn depends upon continuous sensory input. Hallucinations are also common among pilots, astronauts and long-distance truck drivers, and may predispose to accidents.

Solomon, P., Leiderman, P. H., Mendelson, J., Wexler, D.: "Sensory deprivation, a review." *Am. J. Psychiatry* **114**: 357-363 (1957). B29,588/57

Review on the effects of sensory deprivation in man showed that the most evident results are an "intense desire for extrinsic sensory stimuli and bodily motion, increased suggestibility, impairment of organized thinking, oppression and depression, and, in extreme cases, hallucinations, delusions, and confusion" (28 refs.).

Wexler, D., Mendelson, J., Leiderman, P. H., Solomon, P.: "Sensory deprivation. A technique for studying psychiatric aspects of stress." *Arch. Neurol. Psychiatry* **79**: 225-233 (1958). B69,786/58

Sensory deprivation is considered to be a suitable technique for studying the psychiatric aspects of stress. Men placed in a tank-type respirator for periods of up to thirty-six hours experienced perceptual and sensory deprivation which led to an impaired ability to concentrate, distortions in time judgment and anxiety. Several subjects had pseudosomatic delusions, illusions or hallucinations. Correlation of these findings with the pertinent literature led to the conclusion that the most common manifestations are: "(1) the inability of most subjects to tolerate or adapt to the stress of sensory isolation; (2) the subjects' increasing need for and attempts to obtain extrinsic physical and social stimuli; (3) the progressive failure, in certain subjects, of reality contact with the emergence of pathological thought processes and behavior."

Kraft, J. A.: "Measurement of stress and fatigue in flight crews during confinement." *J. Aviat. Med.* **30**: 424 (1959). C70,483/59

Description of an elaborate facility for the automatic registration of various stress indices (skin temperature, heart rate, respiratory cycle, muscular tension, skin conductance, and so on) under the influence of stressors to which flight crews and astronauts are likely to be exposed (for example, gravity forces, loneliness, confinement, isolation, sensory deprivation, and so on).

Zuckerman, M., Albright, R. J., Marks, C. S., Miller, G. L.: "Stress and hallucinatory effects of perceptual isolation and confinement." *Psychol. Monogr.* **76** No. 30: 1-15 (1962). J3,941/62

Observations on student nurses subjected to perceptual isolation through various techniques. The resulting loss of orientation, difficulties in directed thinking, anxiety from personal thoughts and increasing somatic discomfort led to a mounting stress reaction in most subjects. Hallucinations were also common.

Burns, N. M., Kimura, D.: "Isolation and sensory deprivation." In: Burns, N. M., Chambers, R. M. et al., *Unusual Environments and Human Behavior*, pp. 167-192. Glencoe, Ill.: Free Press, 1963.

E10,429/63

Brief review on isolation, loneliness and sensory deprivation in relation to prolonged space flights.

Winters, W. D.: "Various hormone changes during simulated space stresses in the monkey." *J. Appl. Physiol.* **18**: 1167-1170 (1963). E35,060/63

In *Macacca nemestrina* monkeys, diuresis and urinary excretion of 17-KGS and catecholamines were examined under simulated space stressor conditions, namely, centrifugation, vibration and isolation with restraint. The results varied with the type of stressor used, but reduction in urine volume was obvious in all instances. "A fall in steroid and slight elevation in catecholamine excretion were observed following vibration and centrifugation. The centrifugation appeared to be slightly more stressful. Isolation with restraint appears to be a severe stress to the animals as demonstrated by a marked elevation of amine and a marked reduction in both urine output and steroid excretion."

Zuckerman, M.: "Perceptual isolation as a stress situation." *Arch. Gen. Psychiatry* **11**: 255-276 (1964). G19,879/64

Careful evaluation of the literature (68 refs.) on biochemical and physiologic responses to isolation produced by various techniques in normal and abnormal individuals. "Sensory deprivation" (darkness and quiet) is compared with "perceptual deprivation" (unpatterned light and constant "white noise").

Zuckerman, M., Levine, S., Biase, D. V.: "Stress response in total and partial perceptual isolation." *Psychosom. Med.* **26**: 250-260 (1964). J7,193/64

In studies on female undergraduates, the GSR (recorded by the Tissue Resistance Monitor) showed that a ninety-minute period of "total isolation is more stressful than partial isolation. Verbal indices indicate that all types of isolation are equally stressful. The results indicate that a social set theory is not sufficient to explain the stressful effects of perceptual restriction."

Dohrenwend, B. S., Dohrenwend, B. P.: "Stress situations, birth order, and psychological symptoms." *J. Abnorm. Psychol.* **71**: 215-223 (1966). J8,713/66

Studies on college students suggest that—in confirmation of earlier observations—the stress of sensory deprivation is modified by birth order. "First borns show high levels of symptoms when their situation is such that, faced with an anxiety-arousing condition, they have difficulty finding others with whom to share the experience. Later borns show high levels of symptoms when, in the face of anxiety, they are forced into intense interaction with others."

Zubek, J. P., Schutte, W.: "Urinary excre-

tion of adrenaline and noradrenaline during prolonged perceptual deprivation." *J. Abnorm. Psychol.* **71**: 328-334 (1966).

J24,049/66

In young men who successfully completed a week of perceptual isolation, there was no significant change in urinary EP or NEP excretion. However, "quitters" had a significantly lower baseline of EP even months after the isolation experiment, but exhibited an increased excretion during isolation. "These results seem to suggest that isolation quitters may be biochemically or 'constitutionally' different from volunteers who can successfully complete a prolonged period of perceptual isolation."

Pleasure

There is surprisingly little scientific literature on objectively demonstrable indices of stress elicited by pleasure. It is of course common knowledge that sudden joy—like pain or grief—can produce increased adrenergic activity with acceleration of the pulse, a rise in blood pressure and excessive mental arousal. In fact, it was this type of observation that led to the creation of the "eustress" concept, according to which gratifying or health-promoting demands upon the body represent stress just as distress does.

That there is a lack of positive laboratory data supporting this view is probably due primarily to the difficulty encountered in producing chronic states of extreme pleasure for experimental purposes. However, some pertinent observations have been

made quite independently of the research on stress in human beings during sexual intercourse, and several publications make reference to the possibility of sudden death in predisposed people as a consequence of extreme unexpected joy.

Pleasure

(See also our earlier stress monographs, p. xiii)

Engel, G. L.: "Sudden and rapid death during psychological stress. Folklore or folk wisdom?" *Ann. Intern. Med.* **74**: 771-782 (1971). G83.212/71

Excellent and detailed review of the sociologic-demographic literature shows that the causes of sudden death in man may be classified into eight categories: "1) on the impact of the collapse or death of a close person; 2) during acute grief; 3) on threat

of loss of a close person; 4) during mourning or on an anniversary; 5) on loss of status or self-esteem; 6) personal danger or threat of injury; 7) after the danger is over; 8) reunion, triumph, or happy ending" (89 refs.).

Tejmar, J.: "Berlin wall and sudden death." *Ann. Intern. Med.* **78**: 620 (1973).

J19,555/73

Sudden death during joyful meetings after long years of separation has been described, but undoubtedly it is a very rare occurrence.

Handling and Gentling

(See also Age—Perinatal)

Handling and gentling of young animals may influence their subsequent stress resistance, but the underlying mechanism of this phenomenon is not yet clear. First, it must be realized that handling can be experienced as an attack or a friendly gesture, depending upon the individual's reaction to the situation. Surely, handling of fish or other animals that are unaccustomed to it will be experienced by them as an aggression, whereas newborn babies like to be taken up and handled by their mothers.

In animals, especially rats (in which most of the corresponding experiments were performed) it is difficult to judge their associated mental reactions, but in any event, it has been claimed that taking the young away from the mother and placing them in a cage for handling may act as a stressor merely by reducing their surrounding temperature.

Handling and Gentling

Excellent and extensive review, with special reference to the stressor effect of climate (90 refs.).

Pollution

In view of the increasing importance of air and water pollution there exists an enormous literature on this subject. But although chemical agents, microbes, sound, and in a broader sense, "social pollution" by overcrowding of our cities represent potent stressors, comparatively few data are available on their truly nonspecific, measurable stressor effects as such. Most of the relevant publications deal with the psychologic effects of life in polluted, overcrowded, urbanized areas and in concentration camps; in the special sections of this chapter, the reader will find data on the typical stressor effects of these and many other environmental agents.

Pollution

(See also our earlier stress monographs, p. xiii)

Blumer, W.: "Nervöse Störungen durch Autoabgase" (Nervous disturbances caused by automobile exhaust gases). *Praxis* **59**: 1809-1816 (1970). H35,115/70

Automobile exhaust gases are considered to produce stress in man as judged by the resulting symptoms, although elimination of

lead furnishes a rather specific therapeutic measure.

Lindvall, T., Radford, E. P.: "Measurement of annoyance due to exposure to environmental factors." *Environ. Res.* **6**: 1-36 (1973). J15,317/73

Review on various environmental factors, especially sound, pollution, crowding and stressful interpersonal relations, on objective indicators of somatic stress (about 150 refs.).

tion, exercise, and heat stress." *Arch. Environ. Health* **28**: 177-181 (1974).

J11,428/74

Studies on the effects of air pollution (particularly of carbon monoxide and peroxyacetyl nitrate) upon work tolerance at various temperatures, with special reference to the Los Angeles area (20 refs.).

Social, Cultural, Family

Social and cultural stressors are difficult to separate from related agents with which they often overlap. For example, it would be impossible to dissociate the social from the cultural influences which may act as stressors in the life of a particular primitive tribe, or to distinguish these from genetic factors, climate, diet, prevalent diseases, overcrowding, isolation and innumerable other elements to which the social group is exposed.

The stressor effects of epidemics, wars and economic changes are met very differently by people of distinct cultural and ethnic backgrounds. The term "situational stress" has been used to designate the behavior of people acting in groups, but here it is employed in its broadest sense, essentially as a synonym of "difficulty," which is quite unjustified.

The fact that, in Japan, arteriosclerotic CHD is uncommon in comparison with its incidence among the North American white population has led to some speculation about the roles of social and cultural elements in the pathogenesis of this rather typical disease of adaptation to stress. However, the striking differences in nutrition as well as genetic predisposition must also be considered.

Special attention has been given to what is termed "culture stress" or "cross-cultural stress" in relation to the G.A.S. These studies are mainly concerned with the stressors encountered by migrants, "guest workers" and others who are often regarded as undesirable intruders by host populations. These people may suffer from the lack of friendly social contact in addition to being obliged to follow customs, diets and a general philosophy which is foreign to them.

Most of the investigators in this field have limited their assessment of these stressor conditions to questionnaires or the frequency of typical "diseases of adaptation," such as hypertension, gastric ulcers, mental illness. Only a few somewhat inconclusive data are available with respect to the secretion of stress hormones, that is, corticoids or catecholamines.

A rise in plasma FFA is said to be a very sensitive indicator of interpersonal stress.

A special index of culture stress was constructed by comparing traditions and social habits in thirty-seven totally dissimilar societies and races. It was concluded that protest suicide, defiant homicide, drunken brawling, and witchcraft attribution are suitable tentative indicators of this type of stress.

Extensive studies on "the theory of leadership in interpersonal behavior under stress" led to the conclusion that moderate stress tends to improve, whereas severe stress disorganizes, performance.

In any event, there appears to be a consensus that severe social and cultural stress

predisposes to a number of maladies, not only to typical psychosomatic diseases but even to infections, by decreasing resistance.

Even birth order may act as a social stress. In one study, college students faced with anxiety-arousing conditions manifested more distress and had more difficulty in finding others with whom to share their experiences than did their siblings. Of course, conflicts in the family and with coworkers are particularly common social stressors.

Allegedly, chronic alcoholics drink most when stress and socialization periods coincide.

A comparative study in high and low stress areas of Detroit revealed that social and economic factors predispose to hypertension, especially among blacks.

Much attention has also been given to social stress in animals. The well-known "pecking order" is a common source of stress in chickens, and dominance, especially among males, often causes conflict in various mammals.

In chickens subjected to various social groupings, resistance to different infections may be increased or decreased depending upon circumstances; this has been ascribed to nonspecific cross-resistance phenomena characteristic of the G.A.S. Allegedly, the resistance of poultry to certain infections coincides with a rise in blood corticoid levels.

In adult *Tupaia belangeri* (tree shrews), the confrontation of two males immediately results in fighting associated with loss of body weight, liver glycogen, blood hemoglobin and kidney weight, eventually resulting in fatal uremia. This allegedly shows "the great significance which social stress may have in the origin of renal disease—possibly in man as well as in animals." When a male *Tupaia* is defeated by a trained fighter, and separated from him by wire mesh to be protected from further attack, the conquered *Tupaia* exhibits adrenal enlargement with increased ascorbic acid concentrations. Plasma corticoid levels initially drop and then rise above normal. The defeated shrew dies after about twenty days of such "psychosocial stress." Curiously, *Tupaias* exposed to various other stressors also exhibit increased adrenal ascorbic acid, in contrast to most other species.

Studies on colonized squirrel monkeys indicated an elevation of 17-OHCS but unchanged catecholamine and 17-KS excretion. Dominant animals had the highest 17-OHCS and the lowest catecholamine levels, whereas their subordinates showed decreased 17-OHCS and increased catecholamine concentrations. 17-KS levels were related to dominance rank. It was concluded that high adrenocortical activity is perhaps necessary for the maintenance of dominance.

Caudill, W.: "Cultural perspectives on stress." *Symposium on Stress*, pp. 194-208. Washington, D.C.: Army Medical Service Graduate School, 1953. B89,530/53

The stressor effects of epidemics, wars, drastic technologic changes and economic or physiologic deprivation are very different in people of differing cultural and ethnic backgrounds.

Gerard, D. L., Phillips, L.: "Relation of social attainment to psychological and adrenocortical reactions to stress." *Arch. Neurol. Psychiatry* 69: 350-354 (1953).

G85,802/53

A pinball-like device, the Rotter aspiration board, was manipulated by an experimenter so that the subject became inept after a period of successful performance. Subjects with high social attainment showed better adaptive responses and less pronounced increases in corticoid excretion than others because they shifted their goals more realistically after failure.

Lanzetta, J. T.: "Group behavior under stress." *Hum. Relat.* 8: 29-52 (1955).

J10,234/55

An extensive study on the effects of situational stress on the behavior of individuals acting in small groups. [The significance of the term stress as used here is not defined but appears to be equated with the need to overcome difficulties (H.S.).]

Ames, M. M.: "Reaction to stress: a comparative study of nativism." *J. Anthropol.* 3: 17-30 (1957). J2,333/57

Studies on four cultures, Manus (Mead, 1956), Klamath, Modoc and Paviotso (Nash, 1937), and their responses to the stress of culture contact which took various forms of nativistic reactions. An attempt was made "to show the importance of the cultural variable in an analysis of stress and its consequences, and to present an analytic scheme by which nativistic movements can be compared and classified."

Caudill, W.: "Effects of Social and Cultural Systems in Reactions to Stress." *Preventive Medicine and Social Research* (pamphlet), p. 34. New York, 1958. J10,111/58

Review on the roles of stress factors in "developing areas of research of mutual in-

terest to social scientists and specialists in the fields of public health and preventive medicine," prepared under the auspices of the Committee on Preventive Medicine and Social Science Research. The author examines the responses of people living under the most diverse social and cultural conditions throughout the world. "The basic idea in this paper is that stress can manifest itself in one or more of a number of linked open systems, and that the strain on one system can be transmitted to others so that several become involved in the process of adaptation and defense" (51 refs.).

Hill, R.: "Social stresses on the family. I. Generic features of families under stress." *Social Casework* 39: 139-150 (1958).

J3,942/58

Interdisciplinary conference (jointly sponsored by the Family Service Association of America and the Elizabeth McCormick Memorial Fund) on the behavior of families under stress. Analysis of the respective roles of stressor agents, hereditary predisposition and interpersonal relationships that may affect adjustment to crises. Special emphasis is placed upon advice to social agencies regarding policies and practice.

Naroll, R.: "A tentative index of culture-stress." *Int. J. Soc. Psychiatry* 5: 107-116 (1959).

J11,585/59

A tentative index of culture stress in thirty-seven totally dissimilar societies and races, based upon comparison of four symptoms: protest suicide, defiant homicide, drunken brawling and witchcraft attribution. This report reviews the theoretical grounds for supposing each indicator to be a symptom of culture stress, and offers a formal set of definitions, rules and corollaries to delineate each. "The construction of the index is described and its validity and reliability discussed."

Scotch, N. A.: "A preliminary report on the relation of sociocultural factors to hypertension among the Zulu." *Ann. N.Y. Acad. Sci.* 84: 1000-1009 (1960). B42,444/60

Studies on the influence of urbanization upon the incidence of hypertension in Zulus of two African communities.

Barnett, S. A., Eaton, J. C., McCallum, H. M.: "Physiological effects of 'social stress' in wild rats. II. Liver glycogen and blood glucose." *J. Psychosom. Res.* 4: 251-260 (1960). C93,978/60

Torrance, E. P.: "A theory of leadership and interpersonal behavior under stress." In: Petrullo, L. and Bass, B. M., *Leadership and Interpersonal Behavior*, pp. 100-117. New York: Holt, Rinehart and Winston, 1961.

J10,652/61

A theory of the relationship between the G.A.S., leadership and interpersonal behavior is developed and summarized in the following table:

cultural Study of Culture Stress, p. 198. Glencoe, Ill.: Free Press, 1962.

E10,632/62

A monograph on culture stress with reference to the G.A.S. Special attention is given to witchcraft attribution as a symptom of culture stress, and an extensive bibliography on this topic is provided. There is also an index of culture stress, based upon this phenomenon and such others as drunken brawling, defiant homicide, and protest suicide among numerous peoples of different racial and ethnic backgrounds.

Fishman, J. R., Hamburg, D. A., Handlon, J. H., Mason, J. W., Sachar, E.: "Emotional

Stressors	Mediating Variables	Consequences
Failure of group mission or objectives; unrealistic goals		Panic, disorganization, lack of group-task efficiency
Attack by hostile individuals or groups		Apathy, lack of effort, loss of will-to-live
Difficult tasks; frequent repetition of events	DURATION	Excessive hostility, defiance, destructiveness, lawlessness
Sudden emergencies		Exhaustion, collapse, dissolution of group
Deprivation of physical, social, emotional, cognitive, and/or esthetic needs		Overcompensation, all-out effort, victory over superior forces
Discomfort from cold, heat, fatigue, lack of sleep	INTENSITY	Increased speed and group-task efficiency
Lack of group-task structure		Control of panic, maintenance of will-to-live (continue adaptation)
Rigid group-task structure		Excessive disharmony, interpersonal strife, "survival of fittest"
Presence of an incompetent, competitive, hostile, erratic, unpredictable, disloyal, or other deviate member	LEADERSHIP AND INTERPERSONAL BEHAVIOR	Lack of trust, mutiny
History of internal strife		Planning, good group decisions, cooperation
Inadequate training for individual and group tasks		Mutual support and self-sacrifice of members
Loss of a group member		Inventiveness and creativity

Reproduced from *Leadership and Interpersonal Behavior*, Fig. 1, p. 103, 1961, with permission of E. P. Torrance.

[Moderate stress tends to produce performance increments, whereas severe stress results in disorganized performance.]

Kahn, R. L., Wolfe, D. M., Quinn, R. P., Snoek, J. D.: *Organizational Stress: Studies*

in Role Conflict and Ambiguity

, p. 470. New York, London and Sydney: John Wiley & Sons, 1964.

E10,438/64

A monograph on organizational stress, particularly in social and industrial groups. There are some highly interesting data on the roles of conflict and ambiguity as they affect various personalities, but the word stress is used essentially as synonymous with difficulties and not in its now generally accepted medical meaning (about 125 refs.).

Back, K. W., Bogdonoff, M. D.: "Plasma lipid responses to leadership, conformity, and deviation." In: Leiderman, P. H. and Shapiro, D., *Psychobiological Approaches to Social Behavior*, pp. 24-42. Stanford, Cal.: Stanford University Press, 1964.

J11,130/64

Detailed review on plasma FFA as an objective indicator of stress in man, particularly in social interrelations. Plasma FFA levels are very sensitive to changes in autonomic nervous activity, and are especially useful in assessing situational demands and group interactions.

Barnett, S. A.: "Social stress. The concept of stress." In: Carthy, J. D. and Duddington, C. L., *Viewpoints in Biology*, Vol. 3, pp. 170-218. London: Butterworths, 1964.

J15,351/64

Kissel, S.: "Stress-reducing properties of social stimuli." *J. Pers. Soc. Psychol.* **2**: 378-384 (1965).

J8,704/65

Psychogenic stress, measured primarily by GSR, was induced by having subjects solve problems in a laboratory setting. Such situations were less stressful in the presence of a friend than before a stranger. However, "the hypothesis that individuals with strong affiliative motives will show a greater reduction in stress responses than will individuals with weak affiliative motives in the presence of another person was not confirmed."

Gross, W. B., Siegel, H. S.: "The effect of social stress on resistance to infection with *Escherichia coli* or *Mycoplasma gallisepticum*." *Poult. Sci.* **44**: 998-1001 (1965).

J11,921/65

Social stress was induced in chickens by moving males into cages with other birds according to a schedule which kept contact with previously encountered birds to a minimum. After two weeks their resistance to *E. coli* inoculation was increased, but their sensitivity to *Mycoplasma gallisepticum* remained unchanged.

Siegel, H. S., Gross, W. B.: "Social grouping, stress and resistance to coliform infection in cockerels." *Poult. Sci.* 44: 1530-1536 (1965). G37,829/65

In cockerels subjected to various types of social grouping "evidences of mild stress such as lower total leucocytes, increased adrenal weight, reduced bursa weight and/or reduced adrenal cholesterol concentrations were discernible." *E. coli* infection caused more severe leukopenia and raised plasma corticosterone, but under certain conditions there was also evidence of "cross" or 'nonspecific' resistance as suggested by Selye."

Reuck, A. de, Knight, J.: *Conflict in Society*, p. 467. London: J and A Churchill, 1966. E7,234/66

Symposium on conflict in animal and human societies. Stress, in the medical sense, is only occasionally touched upon.

Loudon, J. B.: "Private stress and public ritual." *J. Psychosom. Res.* 10: 101-108 (1966). G39,736/66

Speculations on stress in relation to public ritual, especially in developing countries. Contrary to the belief that people instinctively resist change, it was found that many natives welcome it as long as it does not disrupt their personal lives. The authors present several examples of rituals which presumably began as means of combatting stress.

Kasanen, A., Forsström, J.: "Social stress and living habits in the etiology of peptic ulcer." *Ann. Med. Intern. Fenn.* 55: 13-22 (1966). G39,590/66

Statistical studies on one hundred male patients with peptic ulcers of the stomach or duodenum showed that most of them were self-employed or working on temporary jobs. They were more frequently worried about their economic status, although they were no more in debt than were control patients. "The type of work was assessed to be the same in both groups. The peptic ulcer patients often neglected to take an annual holiday because of their work.... The way of life and character of peptic ulcer patients bear a great resemblance to the ways and nature of patients with coronary disease. Persons who feel that life is hectic and tension-producing and who consume stimulants on a liberal scale run a greater risk of contracting these diseases."

Dohrenwend, B. S., Dohrenwend, B. P.: "Stress situations, birth order, and psycho-

logical symptoms." *J. Abnorm. Psychol.* 71: 215-223 (1966). J8,713/66

Studies on college students suggest—in confirmation of earlier observations—that the stress of sensory deprivation is modified by birth order. "First borns show high levels of symptoms when their situation is such that, faced with an anxiety-arousing condition, they have difficulty finding others with whom to share the experience. Later borns show high levels of symptoms when, in the face of anxiety, they are forced into intense interaction with others."

Syme, S. L., Borhani, N. O., Buechley, R. W.: "Cultural mobility and coronary heart disease in an urban area." *Am. J. Epidemiol.* 82: 334-346 (1966). J8,893/66

The terms social and cultural mobility are used to designate the tendency of certain people to move frequently from one social setting or occupation to another. A study on a rural population showed that some factors associated with residential or sociocultural mobility are especially conducive to CHD. The relevant literature on urbanization, industrialization and so on is discussed (24 refs.).

Lazarus, R. S., Tomita, M., Opton, E. Jr., Kodama, M.: "A cross-cultural study of stress-reaction patterns in Japan." *J. Pers. Soc. Psychol.* 4: 622-633 (1966).

J15,487/66

Comparative studies on the responses of Japanese students and middle-aged adults to stressful motion picture films. "The pattern of mood and the degree and timing of reported distress were similar, and the defensive orientations reduced stress reaction for both subjective and physiological measures. However, the hypothesized interaction between MMPI-scaled personality disposition and defensive orientations was not observed. Unlike Americans, Japanese Ss' skin conductance was almost as high during the benign film as during the stressful film, and their conductance during the stressful film was poorly correlated to the specific stressful scenes."

"Society, stress, and disease." *WHO Chron.* **25**: 168-178 (1971). G85,103/71

Brief review on a meeting of the WHO. Special attention is given to psychosomatic derangements due to social changes.

Corson, S. A.: "The lack of feedback in today's societies. A psychosocial stressor." In: Levi, L., *Society, Stress and Disease*. Vol. 1. *The Psychosocial Environment and Psychosomatic Diseases*, pp. 181-189. London, New York and Toronto: Oxford University Press, 1971. E9,311/71

Predominantly philosophic considerations on the importance of feedback systems in combating psychosocial stressors in today's society.

Naumenko, E. V., Popova, N. K., Starygin, A. G.: "Pituitary-adrenal system of animals in groups and in isolation." *Zh. Obshch. Biol.* **32**: 731-739 (1971) (Russian).

J21,443/71

"The reaction of the pituitary-suprarenal system to seasonal influences in the isolated rats differed markedly from that in the rats kept in groups; in the former the level of corticosterone in May sharply increased as compared with that in winter, while in the latter it decreased." It is concluded that reactivity to stressors is weakened during the summer. In rats with the highest index of dominance, plasma corticosterone levels were particularly low during the winter.

Fine, R.: "The stress of peace." In: Parker, R. S., *The Emotional Stress of War, Violence, and Peace*, pp. 92-100. Pittsburgh, Pa.: Stanwix House, 1972.

E10,442/72

Discussion of the forces in peacetime which lead to periodic outbreaks of war and usually have their roots in frustration. The term stress is used essentially as a synonym for nervous tension, and not in its accepted medical sense.

Allen, H. M.: "Gastrointestinal erosions in wild rats subjected to 'social stress'." *Life Sci. [I]* **11**: 351-356 (1972). G90,995/72

Leshner, A. I., Candland, D. K.: "Endocrine effects of grouping and dominance rank in squirrel monkeys." *Physiol. Behav.* **8**: 441-445 (1972). G90,599/72

17-OHCS, 17-KS and total catecholamine excretions were used as indices of social stress in colonized and isolated squirrel monkeys. "Compared to the isolated animals, the colonized monkeys showed elevated 17-OHCS but unchanged catecholamine and 17-KS levels. In the colonized group the dominant animals had the highest 17-OHCS levels and the lowest catecholamine levels, while the subordinate animals showed lower 17-OHCS levels and elevated catecholamine levels. 17-KS levels were related to dominance rank by a J-shaped function." Presumably, high adrenocortical output is necessary for the maintenance of dominance. These results on primates differ from most studies on rodents, which use other methods to determine dominance.

Holst, D. von: "Renal failure as the cause of death in *Tupaia belangeri* exposed to persistent social stress." *J. Comp. Physiol.* **78**: 236-273 (1972). G93,301/72

When two adult male tree shrews are introduced, they immediately begin to fight. Subsequently, merely seeing the victor induces stress manifestations in the defeated *Tupaia*. This is associated with a constant decline in body weight, liver glycogen, blood hemoglobin and kidney weight, eventually resulting in fatal uremia. "The

evidence from natural populations, when examined along with the findings from tree-shrews, show the great significance which social stress may have in the origin of renal disease—possibly in man as well as in animals."

Holst, D. von: "Die Funktion der Nebennieren männlicher Tupaia belangeri. Nebennierengewicht, Ascorbinsäure und Glucocorticoide im Blut bei kurzem und andauerndem soziopsychischem Stress" (The function of the adrenals in male Tupaia belangeri. Adrenal weight, ascorbic acid and glucocorticoids in the blood after acute and prolonged psychosocial stress). *J. Comp. Physiol.* **78**: 289–306 (1972). G93,303/72

Male *Tupaias*, after being defeated by a trained fighter, were separated from him by a wire mesh so that they could continually see the victor without being attacked. The fight was repeated every one to two days. Under these conditions, the defeated *Tupaias* died in less than twenty days owing to the "psychosocial stress" associated with adrenal enlargement and increased ascorbic acid concentrations. Plasma glucocorticoid levels initially dropped and then rose above normal. An elevation of adrenal ascorbic acid also occurred in *Tupaias* exposed to various other stressors, in contrast to the characteristic depletion in most other species.

Allman, L. R., Taylor, H. A., Nathan, P. E.: "Group drinking during stress: effects on drinking behavior, affect, and psychopathology." *Am. J. Psychiatry* **129**: 669–678 (1972). G96,807/72

A group of three chronic alcoholics "drank most when stress and socialization periods coincided; they drank least when stress and periods of isolation occurred together."

Levi, L. (ed.): *Stress and Distress in Response to Psychosocial Stimuli* (Foreword by Hans Selye), p. 166. Oxford, New York, Toronto, Sydney and Braunschweig: Pergamon Press, 1972. H53,062/72

Very thoughtful analysis of the literature and of the author's personal observations on the G.A.S. in relation to psychosocial stimuli. Detailed description of methodology, including hormone determinations. Special emphasis is placed upon pleasant and unpleasant psychosocial stimuli, stress reactions to sexual stimulation and the relationship between psychologic and physiologic reactions during acute and chronic exposure to stressors in man

Levi, L.: "A synopsis of ecology and psychiatry: some theoretical psychosomatic considerations, review of some studies and discussion of preventive aspects." *Lab. Clin. Stress Res.* (Stockholm) Rep. No. 30: 1–17 (1972). J4,975/72

Theoretic considerations on the role of social and ecologic factors in the development of stress in human society.

Grotjahn, M., Mensen, H.: "Was ist Stress?" (What is stress?). *Hippokrates* **44**: 355–367 (1973). J17,047/73

Crowding

A great many observations on animals and man show that at least under certain circumstances crowding may act as a powerful stressor and produce typical manifestations of the G.A.S., such as adrenal enlargement and hyperactivity, thymicolympathic and gonadal involution with decreased fertility, a special tendency toward the formation of peptic ulcers and sensitivity to infections. Allegedly, crowding can help to maintain normal population density.

In mice and rats, crowding at an early age may even cause lasting changes in the offspring of surviving females, perhaps as a result of deficient lactation.

The direct effects of crowding may be complicated by social rank within a community. For example, among wild mice, low-ranking subjects have the largest adrenals, possibly because they are subjected to more physical and psychologic stress than their "social superiors." Likewise, it has been maintained that grouping of previously isolated mice resulted in the greatest adrenal hypertrophy among the subordinate individuals, and that this change could not be related to the extent of injury caused by fighting.

In chickens, overcrowding definitely diminishes egg production and concurrently produces adrenal hypertrophy, although the two do not run strictly parallel. In any event, this factor is of practical importance in raising poultry.

Especially instructive observations have been made on wild rabbits showing that population growth is significantly inhibited in overcrowded colonies. Similar findings have been reported for a large number of other rodents as well as for dogs, guinea pigs, monkeys, woodchucks, deer and man.

The fact that, in rats, under certain conditions, production of gastric ulcers by restraint was inhibited by crowding may have been related to the rise in ambient temperature of animals kept close together.

The curious phenomenon of "group toxicity" has been described in crowded colonies of mice. It is characterized by emotional paroxysms and high mortality, with myocardial necrosis following treatment with catecholamine precursors and MAO inhibitors. This phenomenon could be prevented by reserpine or chlorpromazine. Allegedly, crowding is a more effective stressor for male than for female mice.

A population study on human behavior under crowded conditions suggested that men become more competitive, somewhat more severe, and like each other less, whereas women tend to be more cooperative and lenient and like each other more. On the other hand, a study on young Swedish soldiers, confined to a small shelter for fifty-two hours, revealed no significant adverse effects upon their social compatibility or psychomotor performance (as judged by pistol shooting skill).

An especially interesting study has been done among hunter-gatherers in Botswana and South-West Africa. The !Kung Bushmen live under crowded conditions by choice; the population density in the total area is 1 person per 10 square miles, and yet they form camps in which they occupy only about 188 square feet per person. Typically, their huts are so near that people sitting at different hearths can hand items back and forth without getting up. Yet their blood pressure is low, even at an advanced age, and their serum cholesterol levels are among the lowest in the world. Apparently, "residential crowding alone does not produce symptoms of psychological stress;" in fact, it seems that interpersonal contact "is supportive rather than stressful" as long as the people know they have the space to get away from each other whenever they so desire. Of course, interpretation of this study is extremely difficult since the tribesmen do not suffer from air pollution, competitive strife, noise and the many other stressors associated with urbanization in Western society.

Crowding

(See also our earlier stress monographs, p. xiii)

Christian, J. J.: "The adreno-pituitary system and population cycles in mammals." *J. Mammal.* 31: 247-259 (1950).

B51,490/50

Review on population cycles in various mammals. These can be largely explained by "exhaustion of the adreno-pituitary system subsequent to the stresses inherent in a high population level, severe climatic conditions, and the demands of the spring breeding season."

Bullough, W. S.: "Stress and epidermal mitotic activity. I. The effects of the adrenal hormones." *J. Endocrinol.* 8: 265-274 (1952). B72,094/52

In rats, the stress of overcrowding causes a more pronounced increase in the size of the adrenal medulla than of the cortex. Simultaneously, the epidermal mitotic rate decreases by 60 percent. "It is suggested that the antimitotic effects of stress may be due to a high rate of secretion of either, or both, of these adrenal [cortical and medullary] hormones." All the reactions are regarded as manifestations of the G.A.S.

Christian, J. J.: "Effect of population size on the adrenal glands and reproductive organs of male mice in populations of fixed size." *Am. J. Physiol.* 182: 292-300 (1955).

C8,490/55

In male mice kept under crowded conditions, adrenal enlargement with involution of the thymus, testes, preputial glands and seminal vesicles is attributed to "density-dependent stress."

Tobach, E., Bloch, H.: "Effect of stress by crowding prior to and following tuberculous infection." *Am. J. Physiol.* 187: 399-402 (1956). J5,559/56

Exposure of mice to the stressor effect of crowding can enhance resistance to subsequent tuberculous infection.

Christian, J. J.: "Reserpine suppression of density-dependent adrenal hypertrophy and reproductive hypoendocrinism in populations of male mice." *Am. J. Physiol.* 187: 353-356 (1956). C27,420/56

Davis, D. E., Christian, J. J.: "Relation of adrenal weight to social rank of mice." *Proc. Soc. Exp. Biol. Med.* 94: 728-731 (1957). C32,828/57

In male "wild-strain mice" kept in groups, there is a significant relationship between adrenal weight and social rank. High-ranking mice have smaller adrenals than low-ranking ones, presumably because the latter group is "subjected to more physical and psychological stressing stimuli."

Christian, J. J.: "A review of the endocrine responses in rats and mice to increasing population size including delayed effects on offspring." *Naval Med. Res. Inst.* August 6, 1957, pp. 443-462. C53,409/57

Rats and mice living under crowded conditions show many manifestations of stress, including a decrease in fertility which may

act as a regulator of population density to maintain an optimal level. Crowding can also cause lasting changes in the offspring of surviving females, probably due to lactational deficiencies.

Christian, J. J., Lemunyan, C. D.: "Adverse effects of crowding on lactation and reproduction of mice and two generations of their progeny." *Endocrinology* 63: 517-529 (1958). C59,942/58

Christian, J. J.: "Lack of correlation between adrenal weight and injury in grouped male albino mice." *Proc. Soc. Exp. Biol. Med.* 101: 166-168 (1959). C68,931/59

Grouping previously isolated mice caused adrenal hypertrophy which was least marked in dominant and most prominent in subordinate animals. Yet the amount of scarring and adrenal weight after such grouping showed no correlation that could be attributed to the degree of injury caused by fighting.

Siegel, H. S.: "The relation between crowding and weight of adrenal glands in chickens." *Ecology* 40: 495-498 (1959). J10,863/59

In laying chickens, crowding increases the adrenal weight, although pituitary and thyroid weights remain unaffected.

Siegel, H. S.: "Egg production characteristics and adrenal function in White Leghorns confined at different floor space levels." *Poult. Sci.* 38: 893-898 (1959). J10,896/59

Crowding definitely diminished egg production in chickens. This was usually accompanied by adrenal hypertrophy, although the two changes did not strictly parallel each other. Presumably, both changes were due to stress.

Griffiths, M. E., Calaby, J. H., McIntosh, D. L.: "The stress syndrome in the rabbit." *C. S. I. R. O. Wildl. Res.* 5: 134-148 (1960). D12,295/60

A review of the literature and observations on wild rabbits indicate that overcrowding of rodents in confined colonies can inhibit population growth—possibly through a stress response, although other factors must be considered. [Curiously, the extensive studies of Kracht on acute hyperthyroidism in stressed rabbits are not even mentioned (H.S.).]

Christian, J. J.: *Naval Med. Res. Inst. Lect. Rev. Ser.* 60/2: 1-49 (1960). J12,691/60

Christian, J. J.: "Phenomena associated

with population density." *Proc. Natl. Acad. Sci. U.S.A.* **47**: 428-449 (1961).

D79,921/61

Crowding produces typical manifestations of the G.A.S. in a variety of species, including *Mus*, *Rattus*, *Microtus*, *Clethrionomys*, *Marmota*, *Oryctolagus*, *Lepus*, *Sylvilagus*, *Cervus*, *Myocastor*, dog, guinea pig, monkey and man. The diminution in gonadotropic hormone production that is associated with increased ACTH secretion characteristic of stress, is an important factor in regulating population density (73 refs.).

Welch, B. L.: "Psychophysiological response to the mean level of environmental stimulation: A theory of environmental integration." *Symposium on the Medical Aspects of Stress in the Military Climate*, pp. 39-99. Washington, D.C.: GPO, 1965. G41,327/65

Review on the relationship between stress and Mean Level of Environmental Stimulation (MLES). Detailed survey of the literature and personal observations on the effects of isolation with sensory deprivation or crowding upon nonspecific responsiveness. Particular attention is given to the influence of the Ascending Reticular Activating System (ARAS) upon the hypothalamus and through it upon ACTH, glucocorticoid and catecholamine discharges. The numerous feedbacks in several mechanisms involved in arousal and relaxation are critically analyzed (205 refs.).

Robert, A., Phillips, J. P., Nezamis, J. E.: "Production, by restraint, of gastric ulcers and of hydrothorax in the rat." *Gastroenterology* **51**: 75-81 (1966). G40,473/66

In rats, restraint produced gastric ulcers and hydrothorax within four to six hours. Overnight fasting prevented the hydrothorax and reduced the gastric ulcerations (contrary to previous reports). Restraint ulcers and

hydrothorax "were also inhibited by crowding of the animals, a rise in ambient temperature, or administration of prednisolone."

Zalis, E. G., Kaplan, G.: "The effect of aggregation on amphetamine toxicity in the dog." *Arch. Int. Pharmacodyn. Ther.* **159**: 196-199 (1966). F62,080/66

Chernov, H. I., Furness, P., Partyka, A. D., Plummer, A. J.: "Age, confinement and aggregation as factors in amphetamine group toxicity in mice." *J. Pharmacol. Exp. Ther.* **154**: 346-349 (1966). F73,732/66

Sethy, V. H., Sheth, U. K.: "Factors affecting amphetamine toxicity in aggregated mice." *Indian J. Med. Sci.* **22**: 364-379 (1968). G60,792/68

Halpern, B., Drudi-Baracco, C., Bessirard, D., Martineau, F.: "Brain monoamines and thyroid hormones on the emotional stress induced by sympathomimetic agents in aggregated animals." In: Jasmin, G., *Endocrine Aspects of Disease Processes*, pp. 47-73. St. Louis, Mo.: Warren H Green, 1968.

E7,616/68

In mice, crowding elicited the syndrome of "group toxicity," characterized by emotional paroxysms and high mortality with myocardial necrosis, following administration of certain catecholamine precursors and MAO inhibitors. Reserpine and chlorpromazine inhibited this phenomenon, whereas thyroid hormones increased sensitivity to it.

Bronson, F. H., Chapman, V. M.: "Adrenal-oestrous relationships in grouped or isolated female mice." *Nature* **218**: 483-484 (1968). F98,042/68

When grouped together in a room with no males, female mice exhibit suppression of estrous cycle, increase of adrenal weights and no change in plasma corticosterone concentrations. "It can be concluded that social stressors do not provide a basis for explaining the suppression of oestrus found in groups of females." The literature suggests that crowding acts as a stressor in males, but this has not been definitely established for females.

Bliss, E. L., Ailion, J.: "Response of neurogenic amines to aggregation and strangers." *J. Pharmacol. Exp. Ther.* **168**: 258-263 (1969). H15,845/69

Aggregation of mice unaccustomed to each other caused a decrease in brain NEP and an acceleration of its catabolism. 5-HT levels remained unchanged, although 5-HIAA con-

centrations in the brain rose, indicating an increased catabolism of 5-HT. "Dopamine levels in brain and its catabolism were unaffected. At the same time no changes in norepinephrine metabolism could be detected in the adrenal, heart or spleen. The intermingling of strangers without aggregation also decreased brain norepinephrine. A more severe stress of footshock to rats not only diminished brain norepinephrine but also radically reduced catecholamine levels in the adrenal and spleen. These observations suggest that emotional disturbances activate the norepinephrine and serotonin systems in brain."

Lidberg, L., Seeman, K.: "Psychomotor performance before and after confinement in a shelter." *Lab. Clin. Stress Res.* (Stockholm) Rep. No. 9: 1-7 (1969). G74,277/69

In young Swedish infantrymen, confinement to a shelter for fifty-two hours did not consistently or markedly influence psychomotor performance as judged by pistol shooting skill.

Fröberg, J., Karlsson, C. G., Levi, L., Lidberg, L., Seeman, K.: "Behaviour and social interaction in an experimental shelter." *Lab. Clin. Stress Res.* (Stockholm) Rep. No. 11: 1-16 (1969). G74,276/69

Young soldiers of the Swedish infantry were confined to a shelter for a fifty-two hour period. "Absence of individual role or sub-group differentiation, subdued activity, and generally positive and bland interpersonal perceptions were noted. Adverse reactions were minor and infrequent."

Fröberg, J., Karlsson, C. G., Lidberg, L., Seeman, K.: "Effects of confinement in an experimental shelter on behaviour, social interaction and psychomotor performance." *Försvarsmed.* **6**: 254-262 (1970).

G85,149/70

In healthy young Swedish soldiers confined to a shelter for fifty-two hours under crowded conditions, objective evidence of stress was minimal.

Friedman, S. B., Glasgow, L. A., Ader, R.: "Differential susceptibility to a viral agent in mice housed alone or in groups." *Psychosom. Med.* **32**: 285-299 (1970).

G76,988/70

"In two strains of mice, individually housed animals were more susceptible to encephalomyocarditis (EMC) virus than those housed in groups." Interferon and antibody levels following virus inoculation did

not explain the differences in resistance. Corticosterone levels at the peak of the circadian rhythm were higher in individually housed mice.

Naumenko, E. V., Popova, N. K., Starygin, A. G.: "Pituitary-adrenal system of animals in groups and in isolation." *Zh. Obshch. Biol.* **32**: 731-739 (1971) (Russian).

J21,443/71

"The reaction of the pituitary-suprarenal system to seasonal influences in the isolated rats differed markedly from that in the rats kept in groups; in the former the level of corticosterone in May sharply increased as compared with that in winter, while in the latter it decreased." It is concluded that reactivity to stressors is weakened during the summer. In rats with the highest index of dominance, plasma corticosterone levels were particularly low during the winter.

Ehrlich, P., Freedman, J.: "Population, crowding and human behaviour." *New Scientist Sci. J.* **50**: 10-14 (1971).

J13,725/71

Studies in urban areas led to the conclusion that "under crowded conditions, men become more competitive, somewhat more severe, and like each other less, whereas women become more cooperative and lenient and like each other more."

Leshner, A. I., Candland, D. K.: "Endocrine effects of grouping and dominance rank in squirrel monkeys." *Physiol. Behav.* **8**: 441-445 (1972).

G90,599/72

17-OHCS, 17-KS and total catecholamine excretions were used as indices of social stress in colonized and isolated squirrel monkeys. "Compared to the isolated animals, the colonized monkeys showed elevated 17-OHCS but unchanged catecholamine and 17-KS levels. In the colonized group the dominant animals had the highest 17-OHCS levels and the lowest catecholamine levels, while the subordinate animals showed lower 17-OHCS levels and elevated catecholamine levels. 17-KS levels were related to dominance rank by a J-shaped function." Presum-

ably, high adrenocortical output is necessary for the maintenance of dominance. These results on primates differ from most studies on rodents, which use other methods to determine dominance.

Draper, P.: "Crowding among hunter-gatherers: The !Kung Bushmen." *Science* **182**: 301-303 (1973).

H76,199/73

"Highly crowded living conditions exist among the !Kung Bushmen, hunter-gatherers who live on the edges of the Kalahari Desert in Botswana and South-West Africa. The !Kung appear to be crowded by choice, and biological indicators of stress are absent. Data indicate that residential crowding alone does not produce symptoms of pathological stress." The population density is approximately one person per 10 square miles, and hence among the lowest in the world. Yet they form camps in which they occupy only about 188 square feet per person. Typically, their huts are so close that people sitting at different hearths can hand items back and forth without getting up. They are hypotensive and their blood pressures do not rise with age; serum cholesterol levels are among the lowest in the world. "The !Kung are unfazed by the press and are able to maintain a multi-sensory, diffuse contact with each other that is supportive rather than stressful."

Gärtner, K., Reznik-Schüller, H., Reznik, G.: "The influence of overcrowding on spermatogenesis, size of Leydig-cell nuclei (histometrical investigation), and the adrenal corticosterone contents in mice." *Acta Endocrinol. (Kbh.)* **74**: 783-791 (1973).

H80,017/73

In mice kept alone or under different conditions of crowding, the adrenal corticosterone levels increased twofold with increasing population, whereas spermatogenesis and Leydig cell size decreased.

DeFeudis, F. V., Marks, J. H.: "Studies on the time course of entry and subcellular distribution of radioactivity of (³H) d-ampheta-

mine in the brains of differentially-housed mice." *Experientia* **29**: 1518-1520 (1973).

H81,970/73

In mice, the accumulation of radio-marked d-amphetamine in synaptic particles of the brain increased after prolonged isolation. [The authors do not specifically relate this to stress (H.S.).]

Hull, E. M., Langan, C. J., Rosselli, L.: "Population density and social, territorial, and physiological measures in the gerbil (*Meriones unguiculatus*)."*J. Comp. Physiol. Psychol.* **84**: 414-422 (1973). J5,208/73

Mongolian gerbils possess a ventral sebaceous gland that they rub against low objects in their environment to mark territorial claims. "Crowding depressed several social interaction measures as well as body, ventral gland, and testis weights. In the mixed-sex groups, paired males and females had heaviest adrenal glands, ventral glands, and marking scores, as well as the highest reproductive rate. Mixed-sex crowding did not depress either social or physiological measures as much as did same-sex crowding."

Svare, B. B., Leshner, A. I.: "Behavioral correlates of intermale aggression and grouping in mice."*J. Comp. Physiol. Psychol.* **85**: 203-210 (1973). J6,969/73

Studies on isolated and group-housed mice "suggest that fear is inversely related to, and reactivity directly related to, aggressiveness. It was speculated that differences in fearfulness and reactivity might contribute to the determination of an animal's particular level of aggressiveness and that certain hormonal manipulations might affect aggressiveness through their effects on these related behaviors."

Lindvall, T., Radford, E. P.: "Measurement of annoyance due to exposure to environmental factors."*Environ. Res.* **6**: 1-36 (1973). J15,317/73

Review on various annoyance-producing environmental factors, especially sound, pollution, crowding and stressful interpersonal relations, as objective indicators of somatic stress (about 150 refs.).

Hull, E. M., Chapin, E., Kastaniotis, C.: "Effects of crowding and intermittent isolation on gerbils (*Meriones unguiculatus*)."*Physiol. Behav.* **13**: 723-727 (1974). J19,281/74

In gerbils, crowding depressed all social and reproductive activities but did not stimulate cortisol production. Intermittent isola-

tion actually aggravated the effects of crowding and caused more fighting, but also failed to elicit any marked adrenocortical stimulation.

Levi, L., Andersson, L.: *Population, Environment and Quality of Life*, p. 142. Stockholm: Goteborgs Offsettryckeri AB, 1974.

E10,629/74

Effect of social factors, crowding, pollution and urbanization upon stress-induced diseases (several hundred refs.).

Welch, B. L., Brown, D. G., Welch, A. S., Lin, D. C.: "Isolation, restrictive confinement or crowding of rats for one year. I. Weight, nucleic acids and protein of brain regions."*Brain Res.* **75**: 71-84 (1974). J14,176/74

Rats living for one year under stressful conditions of isolation or crowding have a diminished DNA content in their telencephalon. The authors suggest the tentative working hypothesis that "stress or high levels of environmental stimulation may accelerate the natural aging-associated loss of neurons from the brain."

Prinz, A. F.: "Alt werden wie Methusalem. Modelldenken und Bedenken für die Menschen von morgen" (To be as old as Methuselah. Model-thinking and reflection for the man of tomorrow). *Eur. Med. Mag.* **14**: 22-26 (1974). J14,317/74

Critical analysis of !Kung bushmen from Botswana in whom crowding fails to cause distress, possibly because, unlike urban existence, it is voluntary and has no negative effect upon the quality of life as they see it.

Hamburgh, M., Mendoza, L. A., Rader, M., Lang, A., Silverstein, H., Hoffman, K.: "Malformations induced in offspring of crowded and parabiotically stressed mice."*Teratology* **10**: 31-37 (1974). J15,934/74

Malformations were induced in fetuses of mice kept under crowded conditions or parabiotically joined during pregnancy. "The abnormalities included amputation of peripheral limb structures, open neural folds, exencephaly, blisters, head, face, and tail malformation, and generalized growth retardation. The hypothesis that the teratogenic and other effects were consequences of prolonged prenatal stress induced by the experimental conditions is supported by the observation that both procedures led in a short time to significant increases in mean maternal adrenal weight."

Isolation

(See also Sensory Deprivation, Crowding, Aerospace Medicine, Captivity, and other sections in which agents are discussed in relation to isolation)

In recent years, special attention has been given to isolation and loneliness in connection with the problems encountered by pilots and astronauts during prolonged flights, but these have already been discussed in their corresponding sections, jointly with the techniques and apparatus recommended for such investigations.

In prisoners who volunteered for solitary confinement, it was found that social isolation may produce a change in subjective feelings, but does not in itself cause considerable mental or psychomotor deterioration. Other studies suggest that there exists a definite difference between the stressor effects of perceptual isolation and those of social isolation. In comparisons of the performance of people working alone or in small groups, it was noticed that task motivation, emotional composure and social compatibility are the main determinant factors; in groups, leadership requires a balance between social distance and ability to mix with people.

In rats, isolation allegedly increases the voluntary consumption of ethanol when drinking water is available as an alternative choice.

In confined puppies, the presence of another puppy decreases the level of emotional distress and helps to maintain homeostasis.

Most of the pertinent studies have been performed on mice, among which certain strains tend to become extremely aggressive during isolation. When male mice are isolated they develop eosinopenia, and brain NEP is significantly lower in groups of twenty than in isolated controls. Allegedly, this may have some influence upon the development of aggressiveness. "Isolation stress" may also be associated with increased metabolic and adrenal activity. Gland extirpation studies have suggested that testoid hormones are probably involved in this response, but corticoids, catecholamines and thyroid hormones also play a role. Adrenalectomy and ACTH injections reduce fighting in isolated mice, whereas dexamethasone increases it.

The production of gastric ulcers in fasting mice is facilitated by isolation.

Increases in adrenal weight and plasma corticosterone with pronounced thymus involution were observed in isolated nonfighters as compared with isolated fighter or paired nonfighter mice. Paired fighters were not used for comparison to exclude the complications of fighting itself. However, isolated fighters had significantly higher adrenal catecholamine levels than did isolated nonfighters. Presumably, isolation-induced aggression in the female mice used in these experiments was directly related to increased sympathetic-adrenal activity but not to corticoid secretion.

In three strains of mice, brain NEP and 5-HT determinations during acquisition of shuttle box avoidance and the development of aggressiveness revealed genetic differences. However, in this series of experiments, no clearcut relationship was found between learning ability, aggressiveness and biogenic amine turnover.

In mice, aggressiveness induced by isolation diminished after adrenalectomy but was restored by dexamethasone though not by testosterone. ACTH decreased aggressiveness in both intact and steroid-treated mice.

The rate of catecholamine synthesis is lower in isolated than in grouped mice, and

intense fighting accelerates the synthesis of both catecholamines and 5-HT in the brain.

In isolated people, circadian rhythms of catecholamines and corticoids are disturbed but become normalized soon after synchronization with the usual social stimuli.

Acad. Sci. (Paris)* **274**: 2263-2267 (1972). J20,220/72

In isolated mice, benzopyrene produces pulmonary tumors more rapidly than in those kept in groups of ten.

Ely, D. L., Henry, J. P.: "Effects of prolonged social deprivation on murine behavior patterns, blood pressure, and adrenal weight." *J. Comp. Physiol. Psychol.* **87**: 733-740 (1974). J17,421/74

→**Hormones.** Welch, B. L., Welch, A. S.: "Effect of grouping on the level of brain nor-epinephrine in white Swiss mice." *Life Sci.* **4**: 1011-1018 (1965). J8,692/65

Mice housed for one week in a group of twenty had significantly lower levels of brain NEP than controls isolated for the same period. These differences may explain isolation-induced aggression and excitability.

Weltman, A. S., Sachler, A. M., Sparber, S. B.: "Endocrine, metabolic and behavioral aspects of isolation stress on female albino mice." *Aerosp. Med.* **37**: 804-810 (1966). G36,883/66

In mice isolated for sixteen weeks, there was increased irritability, viciousness, heightened activity and head-twitching. The results

suggest that in the third to eleventh weeks isolation stress was associated with enhanced metabolic and adrenal activity with suggestions of hypothyroidal trends during the terminal period of the study. Possible relationships between these changes and the pathogenesis of psychoses were noted.

Sigg, E. B.: "Relationship of aggressive behaviour to adrenal and gonadal function in male mice." In: Garattini, S. and Sigg, E. B., *Aggressive Behaviour*, pp. 143-149. New York: Wiley-Interscience, 1969.

J10,865/69

The aggressive behavior of isolated mice was studied by extirpation of various endocrine glands and treatment with diverse hormones. It was concluded that "the male gonadal hormones are critically involved in this response whereas other endocrine changes (adreno-cortical, adreno-medullary and thyroid) may be contributory and consequential."

Gilbert, F. F., Bailey, E. D.: "Visual isolation and stress in female ranch mink particularly during the reproductive season." *Can. J. Zool.* **47**: 209-212 (1969). J20,525/69

"Visual isolation is apparently more stressful to female mink during the anoestrous period but reduces stress during oestrus and pregnancy. The increased adrenal steroid output of control mink as part of the stress syndrome during the critical reproductive period might be responsible for increased *in utero* losses. But increased adrenocortical output associated with the stress of long term visual isolation might result in insufficient gonadal stimulation resulting in fewer pregnancies."

Brain, P. F., Nowell, N. W., Wouters, A.: "Some relationships between adrenal function and the effectiveness of a period of isolation in inducing intermale aggression in albino mice." *Physiol. Behav.* **6**: 27-29 (1971). J10,867/71

In male mice, isolation causes aggressiveness (fighting) which is reduced by adrenalectomy and ACTH injection but enhanced by dexamethasone (17 refs.).

Kriebel, J.: "Exogenous modifications of circadian rhythms of adrenal hormones in man." *J. Interdiscipl. Cycle Res.* **3**: 233-241 (1972). G93,758/72

In a healthy young man, circadian rhythms of EP, NEP, corticoids, 17-KS and other metabolic parameters were examined (1)

under normal conditions, (2) during complete isolation without indication of time and (3) after subsequent return to synchronization with the usual social stimuli. Apparently, such stimuli are important in determining the shape of circadian rhythms owing to "(1) the relative late maxima of the catecholamines in synchronization; (2) the increased amplitude during social activity; (3) the abrupt increase in the level of urinary catecholamine excretion at the conclusion of isolation."

Lovely, R. H., Pagano, R. R., Paolino, R. M.: "Shuttle-box-avoidance performance and basal corticosterone levels as a function of duration of individual housing in rats." *J. Comp. Physiol. Psychol.* **81**: 331-335 (1972).

H79,737/72

In rats, isolation increased plasma corticosterone levels and facilitated both the acquisition and the extinction of shuttle-box avoidance responses. "These findings, together with the recent literature implicating the pituitary-adrenal axis in the control of responding in appetitively motivated tasks, suggest that the condition of housing may be a major parameter affecting performance in a variety of learning paradigms."

Leshner, A. I., Walker, W. A., Johnson, A. E., Kelling, J. S., Kreisler, S. J., Svare, B. B.: "Pituitary adrenocortical activity and intermale aggressiveness in isolated mice." *Physiol. Behav.* **11**: 705-711 (1973).

J7,247/73

In mice, the aggressiveness induced by isolation was diminished following adrenalectomy and was restored by dexamethasone but not by testosterone. ACTH decreased aggressiveness in both intact mice and those with controlled levels of corticosterone and/or testosterone. Presumably, ACTH rather than glucocorticoid levels are the critical parameters in the control of aggressiveness by hormones of the pituitary adrenocortical axis: "ACTH affects aggressiveness independently of its effects on either adrenocortical or gonadal activity."

Modigh, K.: "Effects of isolation and fighting in mice on the rate of synthesis of noradrenaline, dopamine and 5-hydroxytryptamine in the brain." *Psychopharmacologia* **33**: 1-17 (1973).

J7,891/73

The rate of brain catecholamine synthesis is lower in isolated than in grouped mice, and intense fighting rapidly accelerates the synthesis of both catecholamines and 5-HT in the brain.

Goldberg, M. E., Insalaco, J. R., Hefner, M. A., Salama, A. I.: "Effect of prolonged isolation on learning, biogenic amine turnover and aggressive behaviour in three strains of mice." *Neuropharmacology* **12**: 1049-1058 (1973). J8,664/73

In three strains of mice, brain NEP and 5-HT levels were measured during acquisition of shuttle-box avoidance and the development of aggressiveness following isolation of some of the mice. "It is concluded that no clearcut relationship exists among learning ability, aggressive behaviour and biogenic amine turnover rates in isolated or aggregated mice."

Hull, E. M., Chapin, E., Kastaniotis, C.: "Effects of crowding and intermittent isolation on gerbils (*Meriones unguiculatus*)."
Physiol. Behav. **13**: 723-727 (1974).

J19,281/74

In gerbils, crowding depressed all social and reproductive activities but did not stimulate cortisol production. Intermittent isolation actually aggravated the effects of crowding and caused more fighting, but also failed to elicit any marked adrenocortical stimulation.

Schwartz, R., Sackler, A. M., Weltman, A. S.: "Adrenal relationships to aggressiveness in isolated female mice." *Experientia* **30**: 199-200 (1974). H85,604/74

Good review of the literature on the effects of isolation on aggressiveness and adrenal activity in female mice. The present observations revealed an increase in adrenal weight and plasma corticosterone with pronounced thymus involution in isolated nonfighter mice as compared to isolated fighter or paired non-fighter mice (paired fighters were not studied to exclude complications caused by the fighting itself). On the other hand, isolated fighters had significantly higher adrenal catecholamine levels than did isolated nonfighters. From these and other investigations, it was concluded "that isolation-induced aggression in female mice was directly related to increased sympathetic-adrenal activity. Conversely, no direct relationship was noted between adrenocortical activity and aggressiveness" (25 refs.).

Holley, D. C., Evans, J. W.: "Effect of confinement on ovine glucose and immunoreactive insulin circadian rhythms." *Am. J. Physiol.* **226**: 1457-1461 (1974).

H88,015/74

In rams "the plasma glucose rhythm

peaked at 0000, reached a low value at 1600, and was not affected by cage restraint. During cage restraint, the time of maximum plasma insulin concentration was shifted 4 h from 0000 to 0400, and the daily mean concentration was increased 160%, suggesting an increased sensitivity of pancreatic β -cells to glucose."

Hutchins, D. A., Pearson, J. D. M., Sharman, D. F.: "An altered metabolism of dopamine in the striatal tissue of mice made aggressive by isolation." *Br. J. Pharmacol.* **51**: 115-116 (1974). H89,221/74

Stolk, J. M., Conner, R. L., Barchas, J. D.: "Social environment and brain biogenic amine metabolism in rats." *J. Comp. Physiol. Psychol.* **87**: 203-207 (1974). J15,239/74

In rats, isolation caused increased NEP turnover in the brain whereas brain 5-HT metabolism showed minimal changes.

Wise, D. A.: "Aggression in the female golden hamster: effects of reproductive state and social isolation." *Horm. Behav.* **5**: 235-250 (1974). J16,161/74

In female hamsters (which are notoriously more aggressive than males, even under ordinary conditions), isolation enhances aggressive behavior. "Considering social isolation as stressful, increases in prolactin levels could be responsible for high aggression following prolonged isolation, since in rats, stress has been reported to increase prolactin secretion."

Modigh, K.: "Effects of social stress on the turnover of brain catecholamines and

5-hydroxytryptamine in mice." *Acta Pharmacol. Toxicol. (Kbh.)* **34**: 97-105 (1974).

J16,345/74

Male mice that were at first isolated and then brought together immediately started to fight, and exhibited characteristic changes in the turnover of brain catecholamines and 5-HT.

→Metabolites. Sabbot, I. M., McNew, J. J., Hoshizaki, T., Sedgwick, C. J., Adey, W. R.: "Effect of a 30 day isolation stress on calcium, phosphorus and other excretory products in an unrestrained chimpanzee." *Aerosp. Med.* **43**: 142-148 (1972).

H73,921/72

Observations on chimpanzees kept in isolation for thirty days suggest that "the calcium to phosphorus excretion ratio might serve as a physiological stress indicator of Selye's adaptation syndrome (period of resistance)."

Hattingh, J., van Pletzen, A. J. J.: "The influence of capture and transportation on some blood parameters of fresh water fish." *Comp. Biochem. Physiol. [A]* **49**: 607-609 (1974). H93,884/74

Welch, B. L., Brown, D. G., Welch, A. S., Lin, D. C.: "Isolation, restrictive confinement or crowding of rats for one year. I. Weight, nucleic acids and protein of brain regions." *Brain Res.* **75**: 71-84 (1974).

J14,176/74

Rats living for one year under stressful conditions of isolation or crowding have a diminished DNA content in their telencephalon. The authors suggest the tentative working hypothesis that "stress or high levels of environmental stimulation may accelerate the natural aging-associated loss of neurons from the brain."

Captivity

(See also Anxiety, Climate)

Death may be caused by the so-called "shock disease" that develops in some captive wild animals after exposure to minor stressors, such as transfer to new quarters or repairs to an adjacent cage. In these animals, the lymphoid tissues are hyperplastic, the adrenal glands and heart small, liver glycogen stores depleted, and death usually occurs in hypoglycemia. The syndrome has been compared to the exhaustion phase of the G.A.S., but the supportive evidence is not entirely conclusive.

Captive wild Norway rats have comparatively large adrenals and atrophic thymus

glands with other typical manifestations of the G.A.S. in comparison with domesticated controls; this has been ascribed to the more sheltered existence of the latter.

In certain strains of hares kept confined in the presence of a hunting dog, testicular atrophy results as a consequence of fear, but of course, in studying the effects of captivity upon any animal it is difficult to estimate the role of anxiety.

Numerous publications deal with the effects of captivity upon various species, including fish, shrews, ground squirrels, mongooses, dolphins and squirrel monkeys. In general, fertility decreases and the changes noted correspond to those of the stress reaction, but for details the reader must be referred to the abstract section.

Captivity

(See also our earlier stress monographs, p. xiii)

Richter, C. P.: "Domestication of the Norway rat and its implications for the problem of stress." In: Wolff, H. G., Wolf, S. G. Jr. et al., *Life Stress and Bodily Disease*, pp. 19-47. Baltimore: Williams & Wilkins, 1950.

B51,893/50

In wild Norway rats, organ weights (large adrenals, small thymus and so on) as well as many functional characteristics resemble those typical of the G.A.S. In this respect they differ from those of domesticated rats. Presumably, this can be ascribed to the more sheltered existence of the laboratory animals.

Christian, J. J., Ratcliffe, H. L.: "Shock disease in captive wild mammals." *Am. J. Pathol.* **28**: 725-737 (1952).

B74,160/52

In various captive wild animals, shock disease and death occurred after minor stress, such as transfer to new quarters or disturbance by repairs to adjacent cages. In these animals the lymphoid tissues were hyperplastic, the adrenal glands and hearts small, the liver glycogen stores depleted, and the immediate cause of death was hypoglycemia. "Shock disease, therefore, corresponds to the exhaustion phase of Selye's syndrome of general adaptation." [Lymphatic atrophy is not usually associated with the exhaustion phase of the G.A.S. (H.S.).]

Hediger, H.: *Studies of the Psychology and Behaviour of Captive Animals in Zoos and Circuses*, p. 166. London: Butterworths, 1955.

E3,952/55

Extensive monograph on the behavior of wild animals in captivity and during training. [The G.A.S. is not discussed, but many pertinent facts can be deduced from the innumerable observations described (H.S.).]

Milin, R.: "The effects of fright on morphology of testes." *Med. Pregl.* **19**: 453-458 (1966) (Serbo-Croatian).

G60,378/66

In hares kept in captivity in the presence of a hunting dog, testicular atrophy occurs as a consequence of fear.

Hane, S., Robertson, O. H., Wexler, B. C., Krupp, M. A.: "Adrenocortical response to stress and ACTH in Pacific salmon (*Oncorhynchus tshawytscha*) and steelhead trout (*Salmo gairdnerii*) at successive stages in the sexual cycle." *Endocrinology* **78**: 791-800 (1966).

F63,818/66

In the Pacific salmon, plasma 17-OHCS concentrations rose at various phases of migration upstream during the spawning season, as well as after bleeding, confinement in a tank or treatment with ACTH. Spawning steelhead trout showed an even greater increase in plasma corticoids than did spawning salmon after ACTH injection.

Sorenson, M. W., Conaway, C. H.: "Observations on the social behavior of tree shrews in captivity." *Folia Primatol.* (Basel) **4**: 124-145 (1966).

J11,006/66

General review and personal observations on the effects of captivity upon behavior—particularly stress manifestations—in various tree shrews.

Schmidt, J. P., Rehkemper, J. A.: "Myocardial lesions: spontaneous development in captive ground squirrels." *Proc. Soc. Exp. Biol. Med.* **125**: 213-215 (1967).

F80,175/67

In Arctic ground squirrels (*Citellus undulatus*), numerous areas of focal myocardial necrosis developed during captivity. "The etiology of these degenerative changes may be associated with the stress of captivity, but remains to be determined."

Harrison, R. J., Boice, R. C., Brownell, R. L. Jr.: "Reproduction in wild and captive dolphins." *Nature* **222**: 1143-1147 (1969).

H13,797/69

Among various types of dolphins, ulceration of the forestomach occurred during captivity, while the number of pregnancies decreased considerably.

Stemmermann, G. N., Hayashi, T.: "A survey of the normal and morbid anatomy of the Hawaiian feral mongoose." *Am. J. Pathol.* **55**: 67a-68a (1969). H13,927/69

Among Hawaiian feral mongooses, acute stress ulcers are common, and are probably related to the method of capture. Yet the presence of healing ulcers demonstrates that these lesions also occur in the wild.

Vlodaver, Z., Medalie, J., Neufeld, H. N.: "Coronary arteries in young monkeys." *Isr. J. Med. Sci.* **5**: 639-643 (1969). H16,811/69

In young rhesus or vervet monkeys, intimal changes develop in the coronary arteries during captivity, especially if the animals are restricted to small cages and have little exercise. "The possible relation between stress and physical activity and the development of

intimal changes in the captive young monkey are emphasized."

Brown, G. M., Grotta, L. J., Penney, D. P., Reichlin, S.: "Adrenal regulation in the wild captive squirrel monkey: a model of chronic stress." *Can. Psychiatr. Assoc. J.* **15**: 425-431 (1970). G78,935/70

Brown, G. M., Schalch, D. S., Reichlin, S.: "Patterns of growth hormone and cortisol responses to psychological stress in the squirrel monkey." *Endocrinology* **88**: 956-963 (1971). H37,353/71

In squirrel monkeys, various stressors (capture, chair restraint, intense sound and aversive conditioning) increase plasma STH and cortisol levels, but the two responses are not parallel and are presumably regulated by diverse mechanisms. In the case of chair restraint, STH values fall to resting levels whereas cortisol continues to rise.

Hattingh, J., van Pletzen, A. J. J.: "The influence of capture and transportation on some blood parameters of fresh water fish." *Comp. Biochem. Physiol. [A]* **49**: 607-609 (1974). H93,884/74

Concentration Camps, POWs

(See also Isolation)

A very large number of publications deal with the problems of concentration camp inmates and with the "concentration camp survivor syndrome" which may develop long after liberation.

Principal emphasis has been placed upon the psychologic problems related to coping behavior, but of course, it is difficult to distinguish the relative roles played by loss of freedom, poor nutrition, bad treatment, fear and generally deficient hygiene. In these studies, considerable attention has been given not only to the psychologic defense reactions which enabled the prisoners to endure the hardships but also to the actions of their masters who had come to terms with their own entirely inhuman behavior by shifting responsibility to those who gave the orders.

Internees in diverse concentration and labor camps developed remarkably similar symptoms. In general, an initial reactive depression was followed by varying degrees of adaptation, and new cases of psychoneuroses rarely occurred until after liberation.

Many of the survivors developed depression with irrational guilt feelings about the fact that they continued to live, while so many of their fellow inmates died. Several investigators mention that the damage was particularly marked in those imprisoned at an early age and in those who suffered not only psychic injury but perhaps also physical trauma, malnutrition and/or illness.

A fairly constant phenomenon resulted from conflicts at an unconscious level between the wish to get well after liberation and the need to suffer for purposes of

revenge and expiation of the "guilt of survival." These observations show that it is incorrect to ascribe the late symptoms to a "constitutional inadequacy" and to reject compensation claims because the disturbances developed only after liberation.

In both male and female concentration camp survivors, libido and fertility were often diminished owing to deficiencies in sperm formation and amenorrhea. Psychosomatic skin disorders were also common.

Due to the unending process of mourning and the emotionally depleted state of the inmates, life in a concentration camp even affected the second generation at times. Parents were often so handicapped that they regarded their children's normal robust activity as an interference with the mourning process or as an extra burden on their already taxed resources. Consequently, the children became anxious and more disruptive.

In POWs repatriated after captivity in China or North Korea, the "prisoner-of-war syndrome" was described as being mainly characterized by apathy and withdrawal as defensive adjustments.

Concentration Camps, POWs

(See also our earlier stress monographs, p. xiii and cf. Isolation)

Bondy, C.: "Problems of internment camps." *J. Abnorm. Soc. Psychol.* 38: 453-475 (1943). B27,407/43

The effects and after-effects of life in a Nazi concentration camp were analyzed while World War II was still in progress. Principal emphasis was placed upon psychosocial problems.

Bettelheim, B.: "Individual and mass behavior in extreme situations." *J. Abnorm. Soc. Psychol.* 38: 417-452 (1943).

B27,881/43

Detailed review of life in a Nazi concentration camp presented by a former inmate. Major emphasis is placed upon psychologic reactions.

Lipscomb, F. M.: "Medical aspects of Belsen Concentration Camp." *Lancet* September 8, 1945, pp. 313-315. B45,379/45

Uehlinger, E.: "Die pathologische Anatomie der Hungerkrankheit und des Hungerödems" (The pathologic anatomy of famine and nutritional edema). *Helv. Med. Acta* 14: 584-601 (1947). B24,304/47

Study of inmates who died in Nazi concentration camps.

Kral, V. A.: "Psychiatric observations under severe chronic stress." *Am. J. Psychiatry* 108: 185-192 (1951). G85,150/51

Internees in the Theresienstadt concentration camp exhibited remarkably similar psychologic responses—an initial reactive de-

pression followed by varying degrees of adaptation. No new cases of psychoneuroses developed; in fact, "old and long-lasting conditions of that kind improved to such an extent that the patients could be considered as practically cured. After the liberation, however, neurotic reactions could be observed in some of the former internees" (22 refs.).

Cohen, E. A.: *Human Behavior in the Concentration Camp*, p. 295. New York: Universal Library, 1953. E10,422/53

An extensive and very objective report of life in a German concentration camp written by a Dutch-Jewish physician who was a prisoner in Auschwitz for three years. It presents a remarkable description of the adaptive reactions of prisoners under extreme circumstances of ill-treatment, malnutrition, cruel experiments and constant fear of death, and attempts to explain the psychologic defense reactions which enabled many of them to endure these hardships. The author suggests that strict discipline helped their masters come to terms with an entirely inhuman behavior by shifting responsibility to those who gave the orders which were blindly accepted as being justified. According to the *London Times* "it is a human document that is one of the most moving and at the same time scientifically most distinguished books to have come out of the postwar period" (157 refs.).

Cohen, B. M., Cooper, M. Z.: *A Follow-up Study of World War II Prisoners of War*, p. 81. Washington, D.C.: Veterans Administration Medical Monograph, 1954.

E10,273/54

A very extensive compilation of data by the U.S. Army on white male survivors of imprisonment by the Japanese and Germans during World War II, with special emphasis on after-effects (morbidity, mortality). Statistical analysis suggests lasting unfavorable after-effects, but evaluation of the role of stress as such, or of more specific factors (malnutrition, infection, trauma), is difficult.

Strassman, H. D., Thaler, M. B., Schein, E. H.: "A prisoner of war syndrome: Apathy as a reaction to severe stress." *Am. J. Psychiatry* **112**: 998-1003 (1956).

C17,232/56

Psychiatric interviews were conducted with American POWs repatriated by the Chinese and North Koreans to examine the psychologic aspects of the "prisoner of war syndrome," which is characterized mainly by apathy and withdrawal as a defensive adjustment.

Oury, P., Day, J.: "Les troubles digestifs chez les déportés" (Gastrointestinal disturbances in concentration camp inmates). *Presse Méd.* **65**: 2078-2081 (1957).

J11,138/57

Chodoff, P.: "Effects of extreme coercive and oppressive forces: brainwashing and concentration camps." *Am. Handb. Psychiatry* **3**: 384-405 (1959).

G73,927/59

Description of the "concentration camp syndrome" among inmates of Nazi and Chinese camps. Special emphasis is placed upon brain-washing and the development of depression with guilt feelings (78 refs.).

Chodoff, P.: "Late effects of the concentration camp syndrome." *Arch. Gen. Psychiatry* **8**: 323-333 (1963).

G73,925/63

Neurotic symptoms are typical late effects that appear in Nazi concentration camp survivors after liberation. "This stress supplies the necessary and essential conditions responsible for the initial development of the traumatic neurosis which occurs to a greater or lesser extent in all individuals who have been subjected to any considerable degree of the stress." The damage is particularly pronounced in those exposed to stress at an early age, suffering not only psychic injury but perhaps physical trauma, malnutrition or illness. A curious but fairly constant phenomenon results from "conflicts, at an unconscious level between the wish to get well, and the need to suffer for purposes of revenge and

expiation, expressed at the symptomatic level in feelings of guilt over survival."

Lyon, E.: "Das peptische Geschwür, eine Stresskrankheit der Verfolgten. (Neue Gesichtspunkte für die Begutachtung)" (Peptic ulcer as a stress disease of the persecuted. [New viewpoints on testimony]). *Med. Klin.* **58**: 1514-1517 (1963). E27,706/63

In concentration camp survivors, stress ulcers are particularly common, and this has been recognized even in legal testimony.

Cleave, T. L.: "A new approach to peptic ulcer." *Am. J. Proctol.* **15**: 297-307 (1964).

F16,659/64

The common occurrence of peptic ulcers in POWs and concentration camp inmates is not due exclusively to stress but also to a lack of dietary protein and the unappetizing nature of the food received. During stress, gastric emptying-time is prolonged and hence the action of acid upon the mucosa is intensified.

Copelman, L. S.: "Etudes et recherches sur les facteurs endocriniens et psychologiques dans la pathogénie et le traitement de la stérilité" (Studies and research on endocrine and psychologic factors in the pathogenesis and treatment of sterility). *Thérapie* **20**: 459-465 (1965). G30,661/65

In both male and female concentration camp survivors, libido and fertility are often diminished. Sperm formation tends to be abnormal and amenorrhea is common as a consequence of stress, as was shown in the original experiments on the G.A.S.

Hocking, F.: "Human reactions to extreme environmental stress." *Med. J. Aust.* **2**: 477-483 (1965). G34,377/65

Review on stress reactions in men exposed to extreme conditions, particularly starvation, natural disasters and life in concentration camps. It is important to remember that in concentration camp survivors, symptoms often appear late, after liberation. "In the past, their claims for compensation have often been dismissed on the grounds that the persistence of their symptoms indicates that they are 'constitutionally inadequate'."

Venzlaff, U.: "Akute und chronische psychiatrische Syndrome nach Extrembelastungen" (Acute and chronic psychiatric syndromes following extreme stress). *Med. Klin.* **62**: 701-706 (1967). F81,248/67

Observations on inmates of Nazi concen-

tration camps and on very badly treated POWs (39 refs.).

Kral, V. A., Pazder, L. H., Wigdor, B. T.: "Long-term effects of a prolonged stress experience." *Can. Psychiatr. Assoc. J.* **12**: 175-181 (1967). G46,466/67

In a group of twenty ex-Hong Kong POWs it was found that "the accumulation of severe stresses endured over a period of three-and-a-half years led to significant impairment in various areas of nervous and psychological functioning which is still easily detectable twenty years after liberation."

"The survivor syndrome: concentration camp effects." *Sciences* **8**: 32-37 (1968).

F94,111/68

Review of the "survivor syndrome" based on observations by various physicians who examined a large number of former concentration camp inmates. Both the acute and delayed manifestations are described as regards somatic and psychic damage. An important pathogenic factor, "survivor guilt, persists long after relatives have died because the survivor unconsciously identifies with the aggressor."

Chodoff, P.: "The Nazi concentration camp and the American poverty ghetto. A comparison." *J. Contemp. Psychother.* **1**: 27-36 (1968). G73,926/68

Krystal, H.: "Review of the findings and implications of this symposium." *Int. Psychiatry Clin.* 8: 217-229 (1971). J20,186/71

Review of a symposium on "Psychic Traumatization. Aftereffects in Individuals and Communities." Major emphasis is laid upon concentration camp survivors and victims of wars, tornados, floods and other types of disaster.

Nemeth, M. C.: "Psychosis in a concentration camp survivor. A case presentation." *Int. Psychiatry Clin.* 8: 135-146 (1971).

J20,183/71

Sigal, J. J.: "Second-generation effects of massive psychic trauma." *Int. Psychiatry Clin.* 8: 55-65 (1971). J19,883/71

Sigal, J. J., Rakoff, V.: "Concentration camp survival. A pilot study of effects on the second generation." *Can. Psychiatr. Assoc. J.* 16: 393-397 (1971). G86,390/71

Concentration camp survivors manifested great difficulties in self-control and in their ability to handle their children. "The most significant effects appeared to be attributable to the insurmountable process of mourning

and the emotionally depleted state of the parents."

Sigal, J. J., Silver, D., Ellin, B.: "Some Second-generation Effects of Survivors of Nazi Persecution," p. 15. Paper presented at the International Congress of Psychiatry, Mexico City, 1971 (mimeographed).

G87,038/71

Even the children of Nazi concentration camp survivors show behavioral anomalies because of their contact with parents "preoccupied with the unending mourning of the loss of their parents, siblings, etc., and with the various psychological and physical illnesses that have beset them since the war. Because they are so preoccupied, they respond to their children's normal robust activity and need for control as an interference with this mourning process or as an extra burden imposed on their already taxed resources. As a result, the children become anxious and more disruptive."

Straker, M.: "The survivor syndrome: theoretical and therapeutic dilemmas." *Laval Méd.* 42: 37-41 (1971). H34,052/71

Description of the late psychologic consequences characteristic of the "survivor syndrome" in former inmates of Nazi concentration camps.

Neiderland, W. G.: "Clinical observations on the survivor syndrome." In: Parker, R. S., *The Emotional Stress of War, Violence, and Peace*, pp. 284-288. Pittsburgh, Pa.: Stanwix House, 1972. E10,446/72

The "concentration camp survivor syndrome" is discussed and compared to the after-effects of other types of catastrophes. Many interesting observations are reported but are not connected with the stress syndrome as it is known in medicine.

Cohen, S., Taylor, L.: *Psychological Survival. The Experience of Long-term Imprisonment*, p. 217. New York: Pantheon Books, 1972. E10,656/72

Monograph on the effects of captivity, especially long-term imprisonment. Particular attention is given to psychologic changes and to studies on stress and sensory deprivation (only a few key refs.).

Spaulding, R. C., Ford, C. V.: "The Pueblo incident: psychological reactions to the stresses of imprisonment and repatriation." *Am. J. Psychiatry* 129: 17-26 (1972).

"Secondary aging refers to changes resulting from stress, trauma, and infection (all factors in combat and internment)." The life expectancy of POWs after release may be normal or increased, depending upon circumstances during internment.

Relocation and Travel

(See also Circadian Variations, Diseases of Adaptation in Animals—shipping fever; Aerospace, and other sections dealing with stressors likely to be encountered during relocation and travel)

Considerable literature exists on the stressor effect of relocation from a familiar to an unfamiliar environment. Most of this work is concerned with voluntary or en-

forced transfers of entire populations, often into an environment totally differing in climate, culture and ethnic characteristics. Various studies have analyzed the problems of nomads, migrant workers and explorers of Arctic or tropical regions, as well as the effects of long-distance travel. Other experiments have indicated the difficulties of becoming accustomed to prolonged life in hospitals, homes for the aged or schools far removed from home. However, most of these studies have been limited to psychosocial observations with only occasional references to somatic manifestations of the G.A.S.

In psychiatric patients, increased corticoid excretion was noted following their journey to the hospital.

In men on an Antarctic expedition, 17-OHCS elimination as well as blood cholesterol and phospholipid levels were enhanced during the first month of the winter. But most of the pertinent studies have been performed on small groups in which it was virtually impossible to separate the effects of relocation itself from those of numerous incidental associated factors, such as desynchronization of the circadian cycle, variations in temperature, atmospheric pressure and the psychosocial elements that induce people to change their environments.

The classic indicators of stress subject to quantitative measurements have received more attention in animal experiments. Thus, in rats, a slight environmental change caused by transfer from one room to another may be associated with an enormous increase in plasma free corticoid concentrations. In squirrel monkeys captured in Colombia, serum cholesterol rose significantly during transportation to North Carolina. However, most of the changes characteristic of stress in captive wild animals have already been considered in a preceding section.

Relocation, Travel

Simpson, H. W.: "Field studies of human stress in polar regions." *Br. Med. J.* March 4, 1967, pp. 530-533. F78,155/67

In men at a British Antarctic sledging base, eosinopenia was especially marked in the evening after a full day of travel. Similarly, in a party skiing 400 miles across Greenland, 17-OHCS excretion was high during the forty days of crossing from coast to coast. No adaptation to stress occurred.

Novick, L. J.: "Easing the stress of moving day." *Hospitals* **41**: 64-74 (1967).

J24,294/67

Friedman, S. B., Ader, R.: "Adrenocortical response to novelty and noxious stimulation." *Neuroendocrinology* **2**: 209-212 (1967).

F90,171/67

In rats placed in a new experimental cage, plasma corticosterone levels rose almost equally regardless of whether they were exposed to electric shocks. Apparently, "exposure to a new environment, or novelty, may contribute significantly to the adrenocortical response often attributed entirely to the effects of noxious or painful stimulation."

St. Clair, R. W., MacNinch, J. E., Middleton, C. C., Clarkson, T. B., Lofland, H. B.: "Changes in serum cholesterol levels of squirrel monkeys during importation and acclimation." *Lab. Invest.* **16**: 828-832 (1967).

H1,895/67

In squirrel monkeys (*Saimiri sciureus*) captured in Colombia, serum cholesterol rose significantly after transportation to North Carolina. This response was much less obvious in animals kept in a semisecluded environment than in those caged in laboratories with relatively high noise levels and frequent contact with men. The cholesterol changes could be completely accounted for by a similar fluctuation in β -lipoprotein cholesterol without any alteration in α -lipoprotein cholesterol. "It is suggested that the observed changes in serum cholesterol may reflect the squirrel monkeys' reaction to 'stress' resulting from changes in environment." However, the relative importance of relocation, captivity, noise and contact with men is difficult to appraise.

Kral, V. A., Grad, B., Berenson, J.: "Stress reactions resulting from the relocation of an aged population." *Can. Psychiatr. Assoc. J.* **13**: 201-209 (1968). G58,342/68

In subjects relocated to homes for the aged, plasma corticoid levels increased, especially among men who developed organic signs of disease. Of the normal men, 25 percent died within the first six months of relocation, while all normal women survived. More psychotics died than normal subjects.

Tobin, S. S., Etigson, E.: "Effect of stress on earliest memory." *Arch. Gen. Psychiatry* **19**: 435-444 (1968). G61,195/68

With elderly people for whom institutionalization was a severe stressor, reconstruction of their earliest memories was often considerably impaired.

Parker, S., Kleiner, R. J., Needelman, B.: "Migration and mental illness. Some reconsiderations and suggestions for further analysis." *Soc. Sci. Med.* **3**: 1-9 (1969). J22,108/69

Report on migratory groups which provides "little support for 'culture shock' as an explanatory concept. Such variables as goal-striving stress, reference group orientation, and self-esteem are found to be useful, particularly when the presence or absence of certain pathology-linked characteristics in the same individual is considered."

Markus, E., Blenkner, M., Bloom, M., Downs, T.: "Relocation stress and the aged."

In: Blumenthal, H. T., *The Regulatory Role of the Nervous System in Aging*, pp. 60-71. Basel, München and New York: S Karger, 1970. E8,832/70

Relocation of aged persons from an accustomed to an unknown environment increases morbidity and mortality because it "generates stress and discomfort which call forth coping responses from the relocated person beyond those required by familiar routines." Relocation is particularly damaging to males, especially those with severe mental dysfunctions.

Hashmi, F.: "Immigrants and emotional stress." *Proc. R. Soc. Med.* **63**: 631-632 (1970). H26,830/70

"Immigration causes considerable stress, and in dealing with the problems arising from it and the consequent struggle there are bound to be casualties in the form of psychological or even physical breakdown." Classic biochemical indicators of stress are not mentioned.

Olinescu, A., Olinescu, E., Istrate, N., Oprisan, R., Potorac, E.: "Modificari ale raspunsului imun la soareciile de laborator supusi aciunii factorului stress-ant de transport" (Changes in the immune response of laboratory mice undergoing transport stress). *Microbiol. (Bucur.)* **16**: 417-422 (1971) (Roumanian). J19,887/71

In mice, "transport stress" decreases the titer of antibodies and increases mortality following inoculation with pathogenic organisms.

Carlson, E. T., Noel, P. S.: "Stress and behavior in the founding Pilgrims." *Bull. N.Y. Acad. Med.* **47**: 147-160 (1971). G88,713/71

Hansburg, H. G.: "Separation problems of displaced children." In: Parker, R. S., *The Emotional Stress of War, Violence, and Peace*, pp. 241-262. Pittsburgh, Pa.: Stanwix House, 1972. E10,444/72

A paper on the problems of displaced children separated from their families. Various tests show that there are characteristic patterns of response to separation which are useful in personality evaluation as well as in therapy. The term stress is used very loosely.

"Emotional stress in immigrant workers." *Lancet* June 10, 1972, p. 1276.

H56,204/72
Report on emotional stress problems in

immigrant workers, especially those who came to Belgian mines from various parts of the world. They suffered from a sense of isolation, homesickness and difficulties of adaptation to strange customs, particularly the feeling of being unwelcome by the natives. Symptoms included complaints about living conditions, absenteeism, fatigue and increased general morbidity.

Kecmanović, D., Marković, B., Cerić, I.: "Mental disorders in economic emigrants." *Acta Med. Jugosl.* **26**: 319-327 (1972) (Serbo-Croatian). H60,878/72

Mental disorders and even psychoses are comparatively common among emigrants and are attributed to culture-deprivation stress, although no data are reported on classic biochemical stress indices.

Khomulo, P. S., Popov, A. A., Dmitrieva, N. A.: "The changes in the lipid metabolism and excretion of 17-oxy corticosteroids in the urine in members of polar expeditions during the period of adaptation in the Antarctic." *Kardiologiya* **12** No. 9: 48-52 (1972) (Russian). H80,108/72

In men on an Antarctic expedition, 17-OHCS excretion and blood levels of cholesterol and phospholipids were increased during the first month of wintering, presumably as a consequence of enhanced adrenal cortical activity. Subsequently, some of these values tended to return to normal.

Lumsden, D. P.: "The Volta River Project: village resettlement and attempted rural animation." *Can. J. Afr. Stud.* **7**: 115-132 (1973). J15,924/73

Discussion of the stressor effect of Ghana's Volta River Hydroelectric and Resettlement Project upon the local population.

Données étiopathogéniques et cliniques" (The psychopathology of immigrant workers in the Toulouse region. Etio-pathogenic and clinical data). *Bordeaux Méd.* **7**: 633-640 (1974). H85,680/74

Review on the emotional stressor effect of relocation upon immigrants (9 refs.).

Baldwin, D. M., Colombo, J. A., Sawyer, C. H.: "Plasma prolactin, LH, and corticosterone in rats exposed to a novel environment." *Am. J. Physiol.* **226**: 1366-1369 (1974). H88,007/74

In rats exposed to a novel environment, plasma corticosterone levels rose, but the changes in prolactin secretion were greatly dependent upon the presence of other gonadotropic or ovarian hormones.

Lasry, J. C., Sigal, J. J.: "Stress et santé mentale chez un groupe d'immigrants montréalais" (Stress and mental health in a group of Montreal immigrants). *Ann. ACFAS* **41**: 202 (1974). H88,199/74

Walton, J. R.: "Indirect consequences of low-level use of antimicrobial agents in animal feeds." *Fed. Proc.* **34**: 205-208 (1975). H98,529/75

In mammals treated with antimicrobial agents, "one form of stress may be defined in terms of a disturbance of intestinal flora brought on by relocation, group mixing, change of diet, or travel."

Urbanization

(See also Climate, Environment—social, cultural, pollution)

The literature on the stressor effect of urbanization is concerned mainly with problems of town planning, and the avoidance of noise, pollution and psychosocial complications resulting from life in a modern city. However—as in many of the preceding sections on environmental problems—it is difficult to distinguish the stressor effect of urbanization as such from that of its individual components.

In connection with our main topic, it is of interest that in a Zulu population, the stress of urbanization apparently increased the incidence of hypertension, and statistical data suggest that citification predisposes to CHD. In Bedouins and other nomadic Arabs, ulcerative colitis has been noted after settlement in Kuwait City, presumably as a consequence of urbanization. The high incidence of neuroses in certain housing estates has been similarly interpreted.

American blacks of both sexes have higher blood pressure and mortality from heart disease and strokes than do corresponding whites. Pertinent studies in different areas of Detroit suggested that "blood pressure levels were significantly correlated with different patterns of life stress for the essentially working class persons in the high stress area and for the middle class persons in the low stress area."

Urbanization

(See also our earlier stress monographs, p. xiii)

Martin, F. M., Brotherston, J. H. F., Chave, S. P. W.: "Incidence of neurosis in a new housing estate." *Br. J. Prev. Soc. Med.* **11**: 196-202 (1957). J11,592/57

The high incidence of stress-induced neuroses in the population of new housing estates is attributed to adaptive difficulties created by relocation.

Scotch, N. A.: "Sociocultural factors in the epidemiology of Zulu hypertension." *Am. J. Public Health* **53**: 1205-1213 (1963).

J10,864/63

Mean blood pressure was significantly higher in urban than in rural Zulu populations. "There was a relationship between variables observed to be stressful and hypertension."

Selye, H.: "Stress and urban development." *A.I.A. Journal* September, 1969, pp. 74-75. Also in: *Arkitektur* **70**: 41-42 (1970). G60,081/69

Brief summary of a lecture on stress in relation to urbanism.

Harburg, E., Schull, W. J., Erfurt, J. C., Schork, M. A.: "A family set method for estimating heredity and stress. I. A pilot survey of blood pressure among Negroes in high and low stress areas, Detroit, 1966-1967." *J. Chron. Dis.* **23**: 69-81 (1970). G78,153/70

American blacks of both sexes have higher blood pressure and mortality from heart disease and strokes than do corresponding whites. A pilot study of blacks in low and high stress areas of Detroit suggested that "blood pressure levels were significantly correlated with different patterns of life stress for the essentially working class persons in

the high stress area, and for the middle class persons in the low stress area. Briefly, working class persons in the high stress area with higher blood pressure levels (adjusted for sex, age and weight) reported greater economic frustration and more satisfaction (sic) with their marital life and their neighborhood than did their normotensive counterparts in the same tract. In contrast, middle class persons with higher blood pressure levels had higher occupational achievements and aspired to even more than did their normotensive neighbors."

P., *Stressful Life Events: Their Nature and Effects*, pp. 259-273. New York, London and Sydney: John Wiley & Sons, 1974. E10,794/74

Catastrophe, Accidents

(See also Anxiety)

The psychologic responses to catastrophes and disasters of various kinds—particularly those brought about by bombings, earthquakes, floods, combat, tornadoes, or extreme emotional traumas—have certain elements in common which may be ascribed

to their stressor effect. These have been described as apprehensive avoidance, stunned immobility, apathy, depression, docile dependency, aggressive irritability. The literature contains interesting descriptions of behavior during catastrophes as well as suggestions on protective measures against irrational behavior during disasters, but little is said about the purely medical, especially biochemical, aspects of the associated stress responses.

Catastrophe, Accidents

Selye, H., MacLean, A.: "Prevention of gastric ulcer formation during the alarm reaction." *Am. J. Dig. Dis.* **11**: 319-322 (1944). A75,010/44

Brief review of the literature on the frequent occurrence of perforating gastric ulcers among the population of heavily bombed areas during the war, as well as in sailors and soldiers exposed to continual physical and mental strain.

Janis, I. L.: *Air War and Emotional Stress. Psychological Studies of Bombing and Civilian Defense*, p. 280. New York, Toronto and London: McGraw-Hill, 1951. E4,323/51

Monograph on the psychologic consequences of bombing in Hiroshima and Nagasaki, air war in general, and civil defense. [No reference is made to the stress concept in the medical sense, and such terms as adrenal, adrenaline, corticoids, hypothalamus or adaptation syndrome are not even mentioned in the index. The word stress appears to be used as synonymous with mental upset but is nowhere defined, although it is in the title of the book (H.S.).]

Janis, I. L.: "Problems of theory in the analysis of stress behavior." *J. Soc. Issues* **10**: 12-25 (1954). B26,918/54

General discussion of psychologic reactions to catastrophes, particularly tornadoes, bombings, earthquakes, floods and combat. The typical emotional responses to danger are discussed under the following headings: apprehensive avoidance, stunned immobility, apathy and depression, docile dependency and aggressive irritability (15 refs.).

Wallace, A. F. C.: *Human Behavior in Extreme Situations: A Survey of the Literature and Suggestions for Further Research*, p. 35. National Academy of Science, National Research Council Publ. No. 390 (pamphlet). Washington, D.C., 1956. J6,763/56

Susser, M., Stein, Z.: "Civilisation and peptic ulcer." *Lancet* January 20, 1962, pp. 115-119. D46,685/62

"The immediate effects of war are evident in the rise in perforations and deaths from peptic ulcer which followed air-raids and the stress of war." Statistical studies suggest that "because of the sharp rise in morbidity and mortality during this century, peptic ulcer, particularly of the duodenum, has earned a place as one of the 'diseases of civilisation'."

Baker, G. W., Chapman, D. W.: *Man and Society in Disaster*, p. 442. New York: Basic Books, 1962. E10,447/62

Symposium on the roots and consequences of various catastrophes in war and peace. Somatic stress reactions have been considered only by some contributors, but the book does contain interesting observations on the behavior of individuals and groups during disasters.

Latané, B., Wheeler, L.: "Emotionality and reactions to disaster." *J. Exp. Soc. Psychol. Supp.* 1: 95-102 (1966). J17,242/66

Men who observed death and dismemberment in commercial airplane accidents, and who were "independently designated as emotionally nonresponsive, increased communicative behaviors as a function of stress, while emotionally responsive men decreased communication."

Barton, A. H.: *Communities in Disaster. A Sociological Analysis of Collective Stress Situations*, p. 352. Garden City, N. Y.: Doubleday, 1969. E8,320/69

A detailed sociologic study of behavior at times of catastrophe in war and peace. The author speaks of "collective stress" in referring to extreme disaster situations in entire communities, but the purely medical, especially biochemical, aspects of stress reactions are not considered. The volume is of greater value to sociologists than to physicians.

Abram, H. S. (ed.): *Psychological Aspects*

of Stress, p. 98. Springfield, Ill.: Charles C Thomas, 1970. E9,826/70

Proceedings of a symposium sponsored by the University of Virginia School of Medicine and Medical Education for National Defense (MEND). Seven specialists in different aspects of stress discuss psychologic and physiologic reactions to extremely stressful situations such as disasters, life-threatening illness, combat or life in concentration camps and outer space.

Haas, J. E., Drabek, T. E.: "Community disaster and system stress: a sociological perspective." In: McGrath, J. E., *Social and Psychological Factors in Stress*, pp. 264-286. New York, Chicago and San Francisco: Holt, Rinehart and Winston, 1970. E10,327/70

Sociologic studies on stress, especially in connection with group reactions to extreme situations such as community disasters.

Luchterhand, E. G.: "Sociological approaches to massive stress in natural and man-made disasters." *Int. Psychiatry Clin.* 8: 29-53 (1971). J20,180/71

Psychosocial studies on victims of floods, hurricanes, wars and genocide.

Parker, R. S.: *The Emotional Stress of War, Violence, and Peace*, p. 292. Pittsburgh, Pa.: Stanwix House, 1972. E10,440/72

An anthology of papers presented at the symposiums sponsored by the Brooklyn Psychological Association in November 1968 at which representatives of various countries, particularly the U.S.A., spoke about the stressor effects of violence, especially war. Mainly social and psychologic problems are discussed, and the term stress is used rather loosely as a synonym for tension.

Milburn, T. W.: "A comparison of the effects of crises and disasters on values." In: Parker, R. S., *The Emotional Stress of War Violence, and Peace*, pp. 270-283. Pittsburgh, Pa.: Stanwix House, 1972. E10,445/72

Various crises and disasters are considered as "social stressors," and mechanisms of adjustment to them are discussed. The term stressor is used essentially to refer to a state of tension, without being related to medical indices of the stress syndrome.

Luff, K., Karger, J. von: "Zur Frage der Verhaltenskontrolle von Kraftfahrern nach Verkehrsunfällen unter Berücksichtigung des Schuldmasses" (Behavioral self-control of drivers following road accidents with reference to the degree of guilt). *Beitr. Gerichtl. Med.* 31: 18-21 (1973). J17,717/73

The stressor effect of an automobile accident may lead to an immediate disturbance of decision making, conducive to flight from the scene of the accident. The legal implications in German courts are described.

Ziv, A., Israeli, R.: "Effects of bombardment on the manifest anxiety level of children living in kibbutzim." *J. Cons. Clin. Psychol.* 40: 287-291 (1973). J20,147/73

A Hebrew version of the Children's Manifest Anxiety Scale was administered to children in frequently shelled kibbutzim and in others where life was peaceful. Contrary to expectations, there was no great difference in the anxiety level of the two groups.

BIORHYTHMS

(See also Characteristic Manifestations of Stress—sexual cycle)

Stress in relation to such biorhythms as circadian, lunar and seasonal variations, menstrual cycles and so on, has attracted much attention, but comparatively few investigators have described quantitative alterations in parameters indubitably related to nonspecific, that is, stressor effects.

Circadian

Among all biorhythms, circadian variations have probably received the greatest attention, especially in connection with desynchronization as a result of ever more com-

mon travel from one time zone to another. Of course, prolonged space or submarine voyages, and life in subterranean caves or polar regions, where some of the diurnal changes in lighting, sunshine and social activities, including feeding times, deviate from the norm, as well as working in variable shifts during the day make this aspect of "chronobiology" especially timely. For rapid orientation the reader is advised to consult some of the excellent general *review* articles mentioned below. The topics most immediately concerned with the stressor effect of circadian variations are: changes in CRF, corticoids, ACTH, catecholamines, insulin, 5-HT and histamines. Also, there are some data on fluctuations in blood count, stress ulcer formation, and particularly, data comparing the activity of diverse drugs given at different times of the day.

In man, the blood and urinary levels of *corticoids* and their metabolites are generally high between 06:00 and 08:00, and low between 20:00 and 22:00, but this may vary with the time people arise or go to sleep and is considerably deranged among shift workers with uncommon sleeping times. The usual pattern may be interrupted by sudden bursts of corticoid secretion at irregular times throughout the day. According to some investigators, the periodicity is not changed in night workers or blind people, whereas others maintain that the dark-light cycle is an important synchronizer of pituitary-adrenal activity.

Observations on people kept in underground chambers with artificial dark-light cycles, and later in complete darkness, led investigators to the conclusion that social cues are sufficient to maintain the human circadian rhythm in the absence of light. Yet it has been claimed that the dark-light cycle may be an important regulator of circadian pituitary-adrenal activity.

In mice, the circadian rhythm of blood corticosterone changes during various phases of the circannual cycle and differences in lighting are thought to play an important role here.

Perhaps many external signals can act alternately as cues regulating the circadian cycle, and if one pathway is blocked, another can replace it if it recurs regularly at twenty-four-hour periods. This may explain why, under certain circumstances, disturbance of the light-dark cycle or of social cues in daily activities does derange circadian fluctuations in hormone secretion, at least temporarily. The situation is somewhat comparable to that of a blind man who previously depended on his sight for orientation but who has since learned to a remarkable degree how to be guided by touch, sound and other stimuli. However, it appears to be well established, as we shall see later, that the "cue" must be external, since a total interruption of sensory input into the hypophysiotropic area of the hypothalamus definitely abolishes circadian cycles in hormone production. We must abandon the idea of finding "the" signal for circadian rhythms, because we now have definite evidence that many exogenous rhythms can act as time signals (the Germans call them *Zeitgeber*).

In patients with diabetes insipidus, the circadian variations in plasma cortisol are normal, which suggests that vasopressin is not an important neurohumoral regulator of ACTH secretion. One group of investigators claims that approximately half of man's daily cortisol production is achieved during early morning hours and sleep, when secretory episodes are temporally related to REM sleep. It is estimated that corticoids are synthesized during only six hours of the day.

In animals, the circadian cycles in corticoid production are essentially similar, al-

though on this point observations on various species have yielded dissimilar results. In monkeys, cortisol is secreted episodically, increasing in frequency and concentration during the latter part of the night and the early morning hours.

Many of the apparent contradictions in the literature are due to the fact that animals differ in their sleep-wake cycles. For example, rats—so commonly used for this type of experimentation—are essentially nocturnal animals that sleep during most of the day.

In rats, sectioning of the fornix abolishes the circadian variations in plasma corticosterone by raising the lowest and decreasing the highest daily values. The circadian rhythm is also prevented by total deafferentation or selective transection of the anterior pathways to the MBH, but not by transection of the lateral or dorsal and posterior connections to it; yet a basal ACTH secretion is maintained in the absence of neural input.

Allegedly, in rats the pituitary-adrenal response to ether or restraint is not markedly altered by circadian variations in plasma corticosterone levels, but injection of dexamethasone at noon suppresses it, without affecting a rise in corticoids during stress (ether, restraint, handling).

Much less attention has been given to circadian fluctuations in *ACTH* production. The few available data confirm that—as might be expected—it roughly parallels corticoid synthesis.

We also have evidence of circadian variations in *CRF* production. In rats, hypothalamic tissue obtained every three hours revealed an increase in CRF activity from early morning through the midafternoon, coincident with elevated levels of plasma corticosterone. The peak concentration of plasma corticosterone was reached approximately two hours prior to the onset of the dark period; concurrently, there was a precipitous drop in CRF activity, followed by a rapid return to a high level within three hours.

In the rat, CRF activity of the hypothalamus reached a peak at 18:00 and a minimum at 20:00, paralleling plasma corticosterone levels. This CRF rhythm is not significantly affected by adrenalectomy, and hence is presumably independent of a corticoid feedback mechanism.

In pigeons, plasma *STH* reaches a peak at 06:00 and a nadir at 18:00. This curve is correlated with corresponding changes in plasma FFA levels.

The circadian cycles of *catecholamine* production are much less clearcut and are readily influenced by desynchronization and numerous incidental stressors that may affect animals or man during the day.

Also, there is some evidence of diurnal variations in *STH*, *insulin*, *5-HT* and *histamine* production in mammals, but in all these respects the available data are insufficient to justify generalizations. Some results suggest that serotonergic neurons play a role in circadian fluctuations of pituitary-adrenal function, because the *5-HT* content of the hippocampus and amygdala exhibits a circadian rhythm which roughly parallels that of plasma corticosterone; this rhythm can be eliminated by p-chlorophenylalanine, which blocks *5-HT* synthesis. However, this drug has such strong stressor actions in itself that it reduces food intake and causes hypertrophy of the adrenals along with other signs of the alarm reaction, so that “the proposed relation between decreased brain 5-hydroxytryptamine content and pituitary-adrenal periodicity is questioned.”

In mice, eosinopenia is most pronounced at about 03:00 and least between 14:00 and 17:00. The reverse is true in man, but in both species strong light causes eosinopenia at all times, presumably owing to its stressor effect.

In rats, restraint-induced *stress ulcers* of the stomach develop more rapidly during the active night period than during the day. This is another indication of circadian variations in stress responses.

In general, various physiologic and psychologic indicators of desynchronization following flights from *east to west* are of shorter duration than after comparable trips in the opposite direction.

The circadian rhythms in *body temperature* are too well-known to deserve special discussion here, but they also are deranged during desynchronization.

Generalities

(See also our earlier stress monographs, p. xiii)

Sollberger, A.: *Biological Rhythm Research*, p. 461. Amsterdam, London, and New York: American Elsevier, 1965.

E6,390/65

Monograph on biologic rhythms (circadian, lunar, seasonal), with models and a mathematical-statistical analysis of cybernetic mechanisms in general. Their relationship to the G.A.S. is considered in many connections (several hundred refs.).

Luce, G. G.: *Body Time: Physiological Rhythms and Social Stress*, p. 394. New York: Pantheon, 1971. E10,777/71

Monograph on biorhythms, with special reference to their effect upon stress reactions (about 1,200 refs.).

Hatotani, N. (ed.): *Psychoneuroendocrinology*. (Workshop Conf. Int. Soc. Psycho-neuroendocrinology, Mieken, 1973), p. 312. Basel, München and Paris: S Karger, 1974. E10,797/74

Report on a symposium with the participation of numerous experts (predominantly Japanese). Special sections are devoted to "Stress and Biological Rhythm" and "Regulation of Hypothalamo-Pituitary Function."

Kawakami, M. (ed.): *Biological Rhythms in Neuroendocrine Activity*, p. 353. Tokyo: Igaku Shoin, 1974. E10,857/74

Valuable monograph summarizing data on the effect of various biorhythms in relation to hormones and nervous activity, and stress responses (several hundred refs.).

Halász, B., Slusher, M. A., Gorski, R. A.: "Adrenocorticotrophic hormone secretion in rats after partial or total deafferentation of the medial basal hypothalamus." *Neuroendocrinology* **2**: 43-55 (1967). F81,329/67

In rats, a few weeks after deafferentation of the MBH by means of the Halász knife, plasma and adrenal corticosterone levels were greatly increased except in the venous effluent. Unilateral adrenalectomy under ether further elevated the corticosterone levels, and the remaining adrenal underwent compensatory hypertrophy. The circadian rhythm was abolished either by total deafferentation or by selective transection of the anterior pathways to the MBH, but not by transection of the lateral, dorsal and posterior connections to it. Presumably, the anterior pathways convey afferent input for circadian variations. "It is concluded that ACTH secretion of the anterior pituitary is maintained by the MBH in the absence of neural input. For normal ACTH function, however, afferent impulses to the MBH are required."

Matsuyama, H., Ruhmann-Wennhold, A., Nelson, D. H.: "Radioimmunoassay of plasma ACTH in intact rats." *Endocrinology* **88**: 692-695 (1971). H36,540/71

In rats, the ACTH (radioimmunoassay) content of the plasma was higher between 18:00 and 03:00 than between 08:00 and 12:00. This is the opposite of the circadian pattern in man. Metyrapone increased plasma ACTH after two to eight hours. Five minutes after exposure to stress even more pronounced rises were observed.

→**Steroids.** Pincus, G.: "A diurnal rhythm in the excretion of urinary ketosteroids by young men." *J. Clin. Endocrinol. Metab.* **3**: 195-199 (1943). A57,653/43

In healthy young men, 17-KS excretion at night is regularly lower than during the day. Maximum values tend to occur in the morning. The rise may reflect "ordinary daily stresses."

Sandberg, A. A., Eik-Nes, K., Samuels, L. T., Tyler, F. H.: "The effects of surgery on the blood levels and metabolism of 17-hydroxycorticosteroids in man." *J. Clin. Invest.* **33**: 1509-1516 (1954). B99,413/54

Human blood 17-OHCS levels are highest at 08:00 and decline during the day.

Migeon, C. J., Tyler, F. H., Mahoney, J. P., Florentin, A. A., Castle, H., Bliss, E. L., Samuels, L. T.: "The diurnal variation of plasma levels and urinary excretion of 17-hydroxycorticosteroids in normal subjects, night workers and blind subjects." *J. Clin. Endocrinol. Metab.* **16**: 622-633 (1956).

C15,075/56
The circadian rhythm in plasma 17-OHCS levels reached a peak at about 06:00 and a nadir around midnight. It was followed about two hours later by a similar variation in 17-OHCS excretion. This periodicity was not changed in night workers or blind persons.

Nakadate, G. M., Groot, J. de: "Fornix transection and adrenocortical function in rats." *Anat. Rec.* **145**: 338 (1963).

J11,290/63

After complete bilateral transection of the fornix in rats, the circadian variations of corticosterone production disappeared.

Ulvedal, F., Roberts, J. J.: "Study of man during a 56-day exposure to an oxygen-helium atmosphere at 258 mm. Hg total pressure. VI. Excretion of steroids and catecholamines." *Aerosp. Med.* **37**: 572-578 (1966).

F93,442/66

Men kept in a double-walled space cabin simulator in an oxygen-helium atmosphere showed no significant disturbance in glucocorticoid or catecholamine output. A reversal of the corticoid excretion rhythm was noted in subjects who slept during the day and worked throughout the night (22 refs.).

Zimmermann, E., Critchlow, V.: "Effects of diurnal variation in plasma corticosterone levels on adrenocortical response to stress." *Proc. Soc. Exp. Biol. Med.* **125**: 658-663 (1967).

F86,246/67

In rats, the acute pituitary-adrenal response to ether or restraint is not markedly altered by circadian variations in plasma corticosterone levels.

Ader, R., Friedman, S. B., Grotta, L. J.: "'Emotionality' and adrenal cortical function: effects of strain, test, and the 24-hour corticosterone rhythm." *Anim. Behav.* **15**: 37-44 (1967).

G46,135/67

Etude expérimentale au cours de vols commerciaux long-courriers" (Biologic rhythm and time zone differences. Experimental study during long commercial flights). *Concours Méd.* **89**: 3731-3746; 3963-3976 (1967).

G47,151/67

In airline employees on flights from Paris to Anchorage, with eleven hours of time zone difference, there occurred a decrease in diuresis followed by a "rebound" and a disruption in the circadian rhythm of catecholamine and corticoid elimination.

Lafontaine, E., Lavernhe, J., Courillon, J., Medvedeff, M., Ghata, J.: "Influence of air travel east-west and vice-versa on circadian rhythms of urinary elimination of potassium and 17-hydroxycorticosteroids." *Aerosp. Med.* **38**: 944-947 (1967).

H3,611/67

Studies on transatlantic flight crews show that, among various metabolic parameters, 17-OHCS exhibits the clearest circadian variations. After a quick round trip with twenty hours of exposure to a negative time zone change of eleven hours, the circadian rhythm of potassium and 17-OHCS immediately re-establishes concordance with the preexisting reference rhythm. With five days of exposure to a similar time zone change, the circadian eliminatory rhythm of 17-OHCS begins to adapt itself to local time on the third day and becomes complete by the fifth day, by then being the antithesis of the pre-established reference rhythm.

Dixit, B. N., Buckley, J. P.: "Circadian changes in brain 5-hydroxytryptamine and plasma corticosterone in the rat." *Life Sci.* **6**: 755-758 (1967).

J12,743/67

Experiments on rats "do not indicate any specific time-relationship between changes in brain 5-HT and plasma corticosterone," although both show circadian rhythmicity.

Czakó, L., László, F. A., Kovács, K., Faredin, I., Tóth, I.: "Diurnal variations of the plasma cortisol level in diabetes insipidus." *Acta Med. Acad. Sci. Hung.* **26**: 197-201 (1969).

G67,342/69

In patients with diabetes insipidus, the circadian variations in plasma cortisol are normal. Thus "the results obtained do not support the view that under physiological conditions vasopressin would be the neurohumoral regulator of ACTH secretion."

Zimmermann, E., Critchlow, V.: "Negative feedback and pituitary-adrenal function in female rats." *Am. J. Physiol.* **216**: 148-155 (1969).

H6,475/69

In female rats, 100 µg. per kg. of dexamethasone injected subcutaneously at noon suppressed diurnal variations in plasma corticosterone but not its rise during stress (ether, restraint, handling). Apparently, "it is possible on the basis of sensitivity to negative feedback, to dissociate mechanisms underlying nonstress pituitary-adrenal function from those which support acute responses to the stresses used in these studies."

Orth, D. N., Island, D. P.: "Light synchronization of the circadian rhythm in plasma cortisol (17-OHCS) concentration in man." *J. Clin. Endocrinol. Metab.* **28**: 479-486 (1969).

H11,056/69

In man, the dark-light cycle may be an important synchronizer of the pituitary-adrenal circadian rhythms.

Ceresa, F., Angeli, A., Bocuzzi, G., Molino, G.: "Once-a-day neurally stimulated and basal ACTH secretion phases in man and their response to corticoid inhibition." *J. Clin. Endocrinol. Metab.* **29**: 1074-1082 (1969). H15,880/69

In man, submaximal infusion doses of 6-methylprednisolone or dexamethasone led to partial inhibition of nocturnal and early morning urinary 17-OHCS excretion, but no suppression occurred from 22:00 to midnight unless very massive doses of dexamethasone were administered. It is concluded that "the ACTH-secreting system has 2 daily activity phases with different control mechanisms. One in the nocturnal early morning hours is the result of neural activity directed to the hypothalamus, superimposed on the basal activity and responsible for the circadian rhythm. This once-a-day impulse would appear to be linked to the rapid eye movement sleep stages. Corticoid-induced inhibition in submaximal doses is possible only during this phase. The second phase is characterized by a steady basal activity lasting 24 hours. It is independent of the early morning hour impulse and is resistant to all but massive doses of corticoids."

Haus, E., Halberg, F.: "Circannual rhythm in level and timing of serum corticosterone in standardized inbred mature C-mice." *Environ. Res.* **3**: 81-106 (1970). G73,872/70

In mice, blood corticosterone levels are highest during the winter and lowest during the spring and summer. The circadian rhythm likewise varies during the phases of the circannual cycle. Lighting plays an important role in these changes, although the mechanism of its effect is not yet clear (95 refs.).

Conroy, R. T. W. L., Elliott, A. L., Mills, J. N.: "Circadian rhythms in plasma concentration of 11-hydroxycorticosteroids in men working on night shift and in permanent night workers." *Br. J. Ind. Med.* **27**: 170-174 (1970). H24,017/70

Comparative studies of plasma corticoids were made in newspaper printing shop employees who regularly worked at night and in engineering factory workers on monthly rotation shifts. Among the newspaper workers, maximal concentrations were noted around 14:00 when they awoke, whereas the pattern was much more irregular in the engineering shift employees. "It appears that the adrenal cortical rhythm can be adapted to night work in a community in which this is universal, ac-

cepted and lifelong, but that such adjustment is unusual in men on night shift work for limited periods, and whose associates are mainly following a usual nyctohemeral existence."

Hellman, L., Nakada, F., Curti, J., Weitzman, E. D., Kream, J., Roffwarg, H., Ellman, S., Fukushima, D. K., Gallagher, T. F.: "Cortisol is secreted episodically by normal man." *J. Clin. Endocrinol. Metab.* **30**: 411-422 (1970). H24,101/70

It was shown by various techniques that the circadian cycle of cortisol secretion in man is not a smooth curve when analyzed at short time intervals but represents a jagged line, even without periodic exposure to stressors. It has been demonstrated that "approximately half the day's cortisol production is achieved in the early morning hours during sleep and the secretory episodes are temporally related to rapid eye movement sleep although the relationship is not episode for episode. There was no evidence for steady-state conditions in cortisol level in any portion of the sleep-wake day. It was estimated that the adrenals were secreting at most only 6 hr in a day and were quiescent for the remaining 18 hr." This regulation may be programmed by the CNS.

Hamanaka, Y., Manabe, H., Tanaka, H., Monden, Y., Uozumi, T., Matsumoto, K.: "Effects of surgery on plasma levels of cortisol, corticosterone and nonprotein-bound-cortisol." *Acta Endocrinol. (Kbh.)* **64**: 439-451 (1970). H27,377/70

In preoperative patients, plasma cortisol levels reached a peak at 06:00 and a minimum at 22:00. Surgery caused a steep rise two to four hours after the end of the operation. Plasma corticosterone levels roughly paralleled these values. The percentage of nonprotein-bound plasma cortisol remained almost the same throughout the day but also increased after the operations.

Aschoff, J., Fatranská, M., Giedke, H.: "Human circadian rhythms in continuous darkness: entrainment by social cues." *Science* **171**: 213-215 (1971). H33,965/71

Earlier observations have shown that "cycles of illumination intensity and, to a lesser degree, cycles of environmental temperature are the most important *Zeitgebers* for animals. It has been suggested that in man also light is an important *Zeitgeber* or that it is, at least, responsible for the entrainment of some human rhythms." In the present experi-

ments, catecholamines, 17-OHCS and sodium excretion as well as rectal temperature were compared in people kept in underground chambers with artificial light-dark cycles and later in complete darkness. "Social cues are sufficient to entrain human circadian rhythms, and absence of light has no immediate effect on the functions measured."

Moberg, G. P., Scapagnini, U., Groot, J. de, Ganong, W. F.: "Effect of sectioning the fornix on diurnal fluctuation in plasma corticosterone levels in the rat." *Neuroendocrinology* **7**: 11-15 (1971). H36,762/71

In rats, sectioning of the fornix abolishes the circadian variations in plasma corticosterone by raising the lowest and decreasing the highest values during the day.

Singley, J. A., Chavin, W.: "Cortisol levels of normal goldfish, *Carassius auratus* L., and response to osmotic change." *Am. Zool.* **11**: 653 (1971). J12,378/71

In goldfish, blood cortisol levels show a clear-cut circadian rhythm and a particularly rapid increase following exposure to a variety of stressors.

Dunn, J., Scheving, L.: "Plasma corticosterone levels in rats killed sequentially at the 'trough' or 'peak' of the adrenocortical cycle." *J. Endocrinol.* **49**: 347-348 (1971). H37,824/71

Dunn, J., Scheving, L., Millet, P.: "Circadian variation in stress-evoked increases in plasma corticosterone." *Am. J. Physiol.* **223**: 402-406 (1972). H58,314/72

Broussard, G.: "Bioritmi e stress lavorativo" (Biorhythms and the stress of work). *Minerva Med.* **63**: 3919-3924 (1972). H64,707/72

Corticoid secretion is largely dependent upon circadian rhythms which in turn influence man's ability to perform various types of work.

Hale, H. B., Hartman, B. O., Harris, D. A., Williams, E. W., Miranda, R. E., Hosenfeld, J. M.: "Time zone entrainment and flight stressors as interactants." *Aerosp. Med.* **43**: 1089-1094 (1972). J2,017/72

In flight crews on fifty-four-hour bi- or tri-directional transmeridian missions, urinary corticoid and catecholamine excretion showed rhythmic variability which corresponded to the crews' home base even after several time zones had been crossed. Corticoid and catecholamine responses to flight stressors were least pronounced at 22:00 and

most marked at 06:00 Eastern Standard Time, which corresponded to home base. Essentially similar findings were obtained on fifty-hour missions.

Sobczyk, W., Markiewicz, L.: "Catecholamine excretion in urine during work with high emotional load." *Acta Physiol. Pol.* **23**: 59-65 (1972). J6,003/72

In control room employees at a heat and power station, three-shift work did not change the circadian rhythm of catecholamine and 17-OHCS excretion. The urinary catecholamine and steroid levels were comparatively low although EP elimination increased in proportion to physical activity.

Kawakami, M., Seto, K., Kimura, F.: "Influence of repeated immobilization stress upon the circadian rhythmicity of adrenocorticoid biosynthesis." *Neuroendocrinology* **9**: 207-214 (1972). H56,042/72

"A diurnal rhythm was observed in the activity of adrenocorticoid biosynthesis in non-stressed rabbits, with a maximum at 18:00 and a minimum at midnight. When the animals were exposed to 6 h of immobilization, the adrenocortical biosynthetic activity showed an 80% increase at 3 h and a 40% increase at 6 h; the normal rhythmicity was thus disturbed by exposure to this stressor. The lowest level was observed at 9:00 on the next morning, with a 9 h delay."

Begue, R. J., Gustafsson, J. Å., Gustafsson, S. A.: "Diurnal variations in excretion of corticosteroid metabolites in bile from male and female rats." *J. Steroid Biochem.* **4**: 393-400 (1973). J6,681/73

Roussel, A., Daniel, J. Y., Assenmacher, I.: "Les glucocorticostéroïdes circulants du Lapin, et leurs fluctuations nycthémérales" (Circulating glucocorticoids and circadian variations in rabbits). *C.R. Acad. Sci. (Paris)* **277**: 341-344 (1973). J6,395/73

In rabbits, most plasma corticosterone and cortisol undergo circadian variations, with a peak during the day and a drop at the end of the night. However, the two corticoids do not show complete parallelism.

Lengvari, I., Halász, B.: "Evidence for a diurnal fluctuation in plasma corticosterone levels after fornix transection in the rat." *Neuroendocrinology* **11**: 191-196 (1973). H68,128/73

In rats, the circadian variations in plasma corticosterone disappeared immediately after transection of the fornix, although they reap-

peared a few weeks after this operation. It is concluded that, "contrary to the assumption of other authors, the fornix is not the key structure in the mediation of extrahypothalamic influences to the medial basal hypothalamus that are essential for the diurnal rhythm in plasma corticosterone levels."

Asano, Y., Moroji, T.: "Effects of methamphetamine on daily rhythms of hypothalamic norepinephrine, serotonin and plasma corticosterone levels in the rat." *Life Sci.* **14**: 1463-1472 (1974). J13,478/74

Szafarczyk, A., Moretti, J. M., Boissin, J., Assenmacher, I.: "Effect of time of administration of an inflammatory agent on plasma corticosterone and haptoglobin levels in the rat." *Endocrinology* **94**: 284-287 (1974).

H80,857/74

Haptoglobin, a plasma glycoprotein, is synthesized in the liver of rats under the influence of corticosterone and represents a fairly accurate index of the intensity of inflammatory reactions. In rats injected with turpentine, the fastest and highest haptoglobin levels occurred concurrently with maximum corticosterone hypersecretion after injections at 09:00 while persistently low haptoglobin levels resulted from the phlogogen administration at the time of minimal circadian adrenal reactivity (03:00). "These data are consistent with the concept of an adrenocortical control of haptoglobin biosynthesis."

Ramaley, J. A.: "Correlation between fertility and the serum corticosterone rhythm in mice." *Fed. Proc.* **33**: 282 (1974).

H84,020/74

Ramaley, J. A.: "The changes in basal corticosterone secretion in rats blinded at birth." *Experientia* **30**: 827 (1974). H90,545/74

In rats blinded soon after birth, a circadian rhythm in plasma corticosterone still develops, although somewhat later than in controls.

Bruckdorfer, K. R., Kang, S. S., Khan, I. H., Bourne, A. R., Yudkin, J.: "Diurnal changes in the concentrations of plasma lipids, sugars, insulin and corticosterone in rats fed diets containing various carbohydrates." *Horm. Metab. Res.* **6**: 99-106 (1974).

H86,042/74

Daly, J. R., Evans, J. I.: "Daily rhythms of steroid and associated pituitary hormones in man and their relationship to sleep." *Adv. Steroid Biochem. Pharmacol.* **4**: 61-110 (1974). J15,152/74

Detailed review on the function of the hypothalamo-pituitary-adrenal axis during sleep, with a description of the methodology for EEG measurement of sleep and a periodic drawing of blood specimens using an intravenous catheter throughout the night. The plasma corticoids drop gradually from a zenith at 08:00 to a nadir at 00:00. The circadian rhythm of plasma testosterone has been less carefully studied but appears to run parallel to that of cortisol; however, unlike the latter it cannot be inhibited by dexamethasone. The circadian variations of FSH and LH likewise receive comparatively little attention, but sleep-related rises in LH secretion are regularly observed during adolescence. There are two phases of cortisol elimination, "basal" and "impulsive"; only the latter shows an early morning peak sensitive to corticoid inhibition (about 220 refs.).

Singley, J. A., Chavin, W.: "Serum cortisol in normal goldfish (*Carassius auratus L.*)."
Comp. Biochem. Physiol. [A] **50**: 77-82 (1975). H96,696/75

Data on the circadian rhythm of serum cortisol in normal and cold-stressed goldfish.

Carroll, B. J., Heath, B., Jarrett, D. B.: "Corticosteroids in brain tissue." *Endocrinology* (In press). J20,878/

"A clear circadian variation of brain corticosteroid values was found in mice, together with a rapid elevation of the tissue levels in response to stress. Reduction of both plasma and tissue concentrations was observed after adrenalectomy and in response to dexamethasone treatment of mice. Between 24 and 48 hours *post mortem* mouse brain corticosteroid values decreased greatly." Brain areas not concerned with adrenocortical regulation contain particularly large amounts of corticoids.

→**Catecholamines.** Kärki, N. T.: "The urinary excretion of noradrenaline and adrenaline in different age groups, its diurnal variation and the effect of muscular work on it." *Acta Physiol. Scand.* **39** Suppl. 132: 1-96 (1956). C26,120/56

Monograph on catecholamine excretion in man as influenced by circadian variations, age, muscular work, emotional stress and sex (160 refs.).

Fröberg, J., Karlsson, C. G., Levi, L., Lidberg, L., Seeman, K.: "Circadian rhythms in catecholamine excretion, psychomotor performance and ratings of stress and fatigue

during a 75-hour vigil." *Studia Laboris et Salutis* No. 4: 1-4 (1969). G87.093/69

Observations on thirty-one men of different ages who were deprived of sleep for seventy-five hours. Considerable fatigue and a decline in motor performance developed with an increase in EP excretion. The highest rates occurred during early afternoon, and the lowest throughout the night and early morning hours. The amplitude of the circadian rhythm in EP output was raised by sleep deprivation. The NEP elimination curves were much less regular.

Pátkai, P.: "Inter-individual differences in diurnal variations in alertness, performance, and adrenaline excretion." *Acta Physiol. Scand.* 81: 35-46 (1971).

G84,261/71

EP elimination was highest in the morning in habitual morning workers, decreasing gradually during the day, while evening workers showed nearly constant excretion values.

Kriebel, J.: "Exogenous modifications of circadian rhythms of adrenal hormones in man." *J. Interdiscipl. Cycle Res.* 3: 233-241 (1972). G93.758/72

In a healthy young man, circadian rhythms of EP, NEP, corticoids, 17-KS and other metabolic parameters were examined (1) under normal conditions, (2) during complete isolation without indication of time and (3) after subsequent return to synchronization with the usual social stimuli. Apparently, such stimuli are important in determining the shape of circadian rhythms owing to "(1) the relative late maxima of the catecholamines in synchronisation; (2) the increased amplitude during social activity; (3) abrupt increase in the level of urinary catecholamine excretion at the conclusion of isolation."

Asano, Y., Morozi, T.: "Effects of methamphetamine on daily rhythms of hypothalamic norepinephrine, serotonin and plasma corticosterone levels in the rat." *Life Sci.* 14: 1463-1472 (1974). J13,478/74

Fröberg, J. E.: "Circadian rhythms in catecholamine excretion, performance and selfratings." *Lab. Clin. Stress Res.* (Stockh.) Rev. No. 36: 1-22 (1974). J17,328/74

Observations on man "have shown that adrenaline excretion, performance and subjective arousal are low during the night and high during the day even under conditions of sleep deprivation and regularly spaced meals and other activities. Both the physiological and the psychological arousal rhythms had crests in the small hours."

→Insulin. Holley, D. C., Evans, J. W.: "Effect of confinement on ovine glucose and immunoreactive insulin circadian rhythms." *Am. J. Physiol.* 226: 1457-1461 (1974).

H88,015/74

In rams, "the plasma glucose rhythm peaked at 0000, reached a low value at 1600, and was not affected by cage restraint. During cage restraint, the time of maximum plasma insulin concentration was shifted 4 h from 0000 to 0400, and the daily mean concentration was increased 160% suggesting an increased sensitivity of pancreatic β-cells to glucose."

Bassett, J. M.: "Diurnal patterns of plasma insulin, growth hormone, corticosteroid and metabolite concentrations in fed and fasted sheep." *Aust. J. Biol. Sci.* 27: 167-181 (1974).

J13,836/74

→CRF. Hiroshige, T., Sakakura, M., Itoh, S.: "Diurnal variation of corticotropin-releasing activity in the rat hypothalamus." *Endocrinol. Jap.* 16: 465-467 (1969).

H20,407/69

In rats, there was a close temporal relationship between the CRF activity of the hypothalamus and plasma corticosterone levels, with a peak at 18:00 and a minimum between 04:00 and 08:00. The animals were placed in a lighted room between 06:00 and 19:00 and in darkness between 19:00 and 06:00.

David-Nelson, M. A., Brodish, A.: "Evidence for a diurnal rhythm of corticotrophin-releasing factor (CRF) in the hypothalamus." *Endocrinology* 85: 861-866 (1969).

H18,530/69

In rats, hypothalamic tissue was obtained every three hours and assayed on recipients which were either corticoid-treated or lesioned in the ventral hypothalamus. CRF activity was estimated by the resulting rise in plasma corticosterone. "A gradual increase in CRF activity was found from early morning through midafternoon coincident with increasing levels of plasma corticosterone. At the time of the peak concentration of plasma corticosterone, approximately 2 hr prior to the onset of the dark period, a precipitous drop in CRF activity was observed, followed by a rapid return of CRF activity at the next 3-hr interval."

Hiroshige, T., Sato, T.: "Postnatal development of circadian rhythm of corticotropin-releasing activity in the rat hypothalamus." *Endocrinol. Jap.* 17: 1-6 (1970).

H27,251/70

In rats, the circadian rhythm of plasma corticosterone (a peak in the evening and a nadir in the morning) as well as concurrent circadian variations in hypothalamic CRF content become detectable only when the animals are about three weeks of age.

Hiroshige, T., Sakakura, M.: "Circadian rhythm of corticotropin-releasing activity in the hypothalamus of normal and adrenalectomized rats." *Neuroendocrinology* 7: 25-36 (1971).

H36,764/71

In the rat, the CRF activity of the hypothalamus shows a definite circadian rhythm with a peak at 18:00 and a minimum at 08:00. This closely parallels plasma corticosterone levels. The CRF rhythm is not significantly affected by adrenalectomy and hence it is presumably of neural origin, independent of the negative corticoid feedback mechanism.

Seiden, G., Brodish, A.: "Persistence of a diurnal rhythm in hypothalamic corticotropin-releasing factor (CRF) in the absence of hormone feedback." *Endocrinology* 90: 1401-1403 (1972).

H54,781/72

Through use of an improved pituitary incubation method, "a diurnal rhythm of hypothalamic CRF activity in hypophysectomized rats was detected which parallels the rhythm found in intact rats. Absolute levels of hypothalamic CRF activity were higher in the hypophysectomized rats than in the intact rats at all times of the day tested." Although ACTH and/or corticoids influence the concentration of CRF, the diurnal rhythm of its activity is independent of hormonal feedback.

Hiroshige, T., Abe, K.: "Dynamics of activity of hypothalamic corticotropin releasing factor in the rat." *J. Physiol. Soc. Jap.* 34: 529-530 (1972). H79,788/72

In rats, the circadian rhythm in hypothalamic CRF content (with a peak in the afternoon and a nadir in the morning) develops after two to three weeks of postnatal life, whereas responses to stress occur as early as the seventh day. The circadian rhythm persists in the absence of circulating corticosterone and hence appears to be dependent only upon nervous regulation, not upon negative feedback.

Takebe, K., Sakakura, M.: "Circadian rhythm of CRF activity in the hypothalamus after stress." *Endocrinol. Jap.* 19: 567-570 (1972).

J17,033/72

In intact, adrenalectomized or hypophysectomized rats, the increment in the CRF content of the ME after ether stress was greatest at 08:00 and smallest at 18:30. The final poststress level was essentially the same, but the resting level was highest in the late afternoon. "Thus it is likely that the response of ACTH release to stimulus is not influenced by the diurnal rhythm of plasma corticoids or ACTH, but is related to other factors such as inherent neural sensitivity to stress."

Hiroshige, T.: "Circadian rhythm of corticotropin-releasing activity in the rat hypothalamus: an attempt at physiological validation." In: Kawakami, M., *Biological Rhythms in Neuroendocrine Activity*, pp. 267-280. Tokyo: Igaku Shoin, 1974.

J17,356/74

Correlation between the stress-induced increase and the circadian rhythm of CRF activity in the rat hypothalamus (72 refs.).

→ **Other Hormones.** Mandell, A. J.: "Some determinants of indole excretion in man." In: Wortis, J., *Recent Advances in Biological Psychiatry*, Vol. 5, pp. 237-256. New York: Plenum Press, 1963.

D68,081/63

Indole and corticoid excretion showed similar circadian variations and rises after ACTH treatment or exposure to stressors (70 refs.).

Scapagnini, U., Moberg, G. P., Loon, G. R., van Groot, J. de, Ganong, W. F.: "Relation of brain 5-hydroxytryptamine content to the diurnal variation in plasma corticosterone in

the rat." *Neuroendocrinology* 7: 90-96 (1971). H36,747/71

In rats, the 5-HT content of the hippocampus and amygdala exhibits a circadian rhythm which roughly parallels that of plasma corticosterone. p-Chlorophenylalanine (PCPA), which blocks 5-HT synthesis, increases the a.m. and decreases the p.m. plasma corticosterone levels so that the circadian variations are largely eliminated. "The results suggest that 'serotonergic' neurons play a role in the diurnal fluctuation in pituitary-adrenal function."

Vaisf'd, I. L., Il'icheva, R. F.: "Diurnal rhythm of the content of biogenous amines (histamine, serotonin) in human blood under normal conditions and during altered work-sleep cycles." *Kosm. Biol. Med.* 6 No. 5: 56-62 (1972) (English translation of Russian original). H79,765/72

The histamine-diaminoxidase system shows considerable circadian variations in healthy subjects. The blood 5-HT content tends to decrease at night. Changes in the work-sleep cycle cause fluctuations in these parameters "related not only to the stressor applied, but also to the initial state of the organism." These findings are especially important in space medicine.

Delft, A. M. L. van, Kaplanski, J., Smelik, P. G.: "Circadian periodicity of pituitary-adrenal function after p-chlorophenylalanine administration in the rat." *J. Endocrinol.* 59: 465-474 (1973). H80,867/73

Several investigators have suggested that the circadian periodicity of the pituitary-adrenal axis is regulated by 5-HT and abolished by p-chlorophenylalanine (PCPA). It has now been shown that in rats PCPA-induced changes in pituitary-adrenal periodicity coincide with reduced food intake and body growth, adrenal enlargement and other signs of stress. In view of these marked stressor actions of the drug, "the proposed relationship between decreased brain 5-hydroxytryptamine content and pituitary-adrenal periodicity is questioned."

Asano, Y., Moroji, T.: "Effects of methamphetamine on daily rhythms of hypothalamic norepinephrine, serotonin and plasma corticosterone levels in the rat." *Life Sci.* 14: 1463-1472 (1974). J13,478/74

→**Morphology.** Pincus, G.: "Studies of the role of the adrenal cortex in the stress of

human subjects." *Recent Prog. Horm. Res.* 1: 123-145 (1947). 98,426/47

Excellent review on the biochemical changes characteristic of the G.A.S. in man, with special reference to 17-KS excretion and blood count as influenced by circadian variations, the stresses of daily life, operating a Hoagland-Werthessen pursuit meter, flying and exposure to heat. The response of schizophrenics is abnormal in many respects, and the question is raised whether adrenal malfunction may play a pathogenic role in mental disease (20 refs.).

Louch, C., Meyer, R. K., Emlen, J. T.: "Effect of stress on diurnal fluctuations in eosinophils of the laboratory mouse." *Proc. Soc. Exp. Biol. Med.* 82: 668-671 (1953).

B82,222/53

In mice there are pronounced circadian variations in eosinophil counts showing peaks during the day and drops during the night, presumably owing to the characteristic nocturnal activity of this species. Exposure to cold decreases the eosinophil count but does not eliminate the circadian fluctuations. Presumably, nocturnal activity in these experiments acts as a secondary stress superimposed upon the sustained stress of exposure to cold, and the adrenal gland "is capable of responding further to the daily stress of nocturnal activity."

Hollwich, F., Tilgner, S.: "Reaktionen der Eosinophilen-Zahl auf okulare Lichtreize" (Changes in blood eosinophil count after ocular light stimulation). *Dtsch. Med. Wochenschr.* 89: 1430-1436 (1964). F17,971/64

The blood eosinophil count reaches a maximum in man and a minimum in mice at about 03:00. The reverse is true between 14:00 and 17:00. In both species, intense light causes eosinopenia at all times; this is ascribed to its stressor effect and the resulting alarm reaction.

Kreyberg, L., Evensen, A., Iversen, O. H.: "Influence of stress on the diurnal rhythm in the mitotic activity in the epidermis of hairless mice." *Acta Pathol. Microbiol. Scand.* 64: 176-184 (1965). G31,802/65

In hairless mice, epidermal mitotic counts show regular circadian variations due to the duration, not the rate, of mitoses. This is true even after the circadian rhythmicity has been markedly changed by "acoustic stress."

+**Varia.** Ader, R.: "Gastric erosions in the rat: effects of immobilization at different

points in the activity cycle." *Science* **145**: 406-407 (1964). F16,095/64

Ader, R.,: "Behavioral and physiological rhythms and the development of gastric erosions in the rat." *Psychosom. Med.* **29**: 345-353 (1967). H62,749/67

Rats develop stress ulcers of the stomach much more readily if they are *immobilized* during the active (18:00 to 03:00) period than during the inactive period of their diurnal cycle.

Chou, B. J., Besch, E. L.: "Feeding biorhythm alterations in *heat-stressed* rats." *Aerosp. Med.* **45**: 535-539 (1974).

J13,391/74

Fioretti, M. C., Riccardi, C., Menconi, E., Martini, L.: "Control of the circadian rhythm of the body temperature in the rat." *Life Sci.* **14**: 2111-2119 (1974).

J14,493/74

"The circadian rhythm of the rat body

temperature is abolished in rats kept either in constant dark or light or blinded. The suppressive effects act most likely via the retinas. The rhythm can be inverted by reversal of the *lighting* regimen and it is unaffected by pinealectomy. Most likely the circadian rhythm is not related to changes in patterns of motor activity" (15 refs.).

Davies, J. A., Navaratnam, V., Redfern, P. H.: "The effect of phase-shift on the passive avoidance response in rats and the modifying action of chlordiazepoxide." *Br. J. Pharmacol.* **51**: 447-451 (1974).

H92,485/74

"In rats trained to a 12 h light-12 h dark cycle, advancing the phase by 6 h produced a resynchronization of the 24 h variation in passive avoidance response (PAR) which was completed after 10 days." *Chlordiazepoxide* lessened the disruptive effect of phase-shift. The clinical implications of this work are discussed.

Seasonal Variations

In rats, tourniquet shock and traumatic injuries produce greater mortality in November than in June or July. The cause of this seasonal variation is unknown.

The plasma corticosterone and ascorbic acid levels of the rat do not appear to show any consistent seasonal changes. However, in mice, blood corticosterone levels are allegedly highest during the winter and lowest throughout the spring and summer. The circadian rhythms likewise differ during various phases of the circannual cycle; this may explain some contradictory observations on diurnal variations in the corticoid production of rodents.

Seasonal Variations

(See also our earlier stress monographs, p. xiii)

Ankier, S. I., Dawson, W., Karady, S., West, G. B.: "Seasonal variation in the resistance of rats." *J. Pharm. Pharmacol.* **17**: 187-188 (1965). G26,781/65

In the rat, traumatic shock (Noble-Collip drum) and tourniquet shock elicited greater mortality in November than in June or July. The cause of this seasonal variation in stress resistance could not be determined.

Sanchez, C., Miya, T. S., Bousquet, W. F.: "Effects of conditioning upon stress responses in the rat." *Proc. Soc. Exp. Biol. Med.* **123**: 615-618 (1966). F73,973/66

Pretreatment of rats with small amounts of intravenous sodium chloride for five days

inhibited the marked elevation of plasma corticosterone induced by saline in nonpretreated controls. Similar pretreatment offered no protection, however, against the more pronounced stressor effect of intravenous histamine. The resting plasma corticosterone and ascorbic acid levels did not show any consistent seasonal variation and there was no manifest relationship between the two values. This "suggests that caution be employed in relying upon adrenal ascorbic acid determinations as an index of adrenocortical activity or response to stressors."

Aschoff, J.: "Adaptive cycles: their significance for defining environmental hazards." *Int. J. Biometeorol.* **11**: 255-278 (1967).

J7,197/67

Review of various biorhythms (circadian,

lunar, seasonal) that clearly distinguishes the endogenous from those depending upon environmental factors, particularly stress. Among the seasonal rhythms, it is interesting that acts of violence and riots occur most frequently during the warm season, and that in six European countries monthly suicide rates invariably peak during the summer (about 60 refs.).

Fontaine, M.: "Les poissons migrateurs" (Migrating fish). *Atomes* **24**: 715-720 (1969). G81,184/69

Brief semipopular review on the stressor effect of seasonal migration in fish.

Haus, E., Halberg, F.: "Circannual rhythm in level and timing of serum corticosterone in standardized inbred mature C-mice." *Environ. Res.* **3**: 81-106 (1970).

G73,872/70

In mice, blood corticosterone levels are highest during the winter and lowest during the spring and summer. The circadian rhythm likewise varies during the phases of the circannual cycle. Lighting plays an important role in these changes, although the mechanism of its effect is not yet clear (95 refs.).

Naumenko, E. V., Popova, N. K., Starygin, A. G.: "Pituitary-adrenal system of animals in groups and in isolation." *Zh. Obshch. Biol.* **32**: 731-739 (1971) (Russian).

J21,443/71

"The reaction of the pituitary-suprarenal system to seasonal influences in the isolated

rats differed markedly from that in the rats kept in groups; in the former the level of corticosterone in May sharply increased as compared with that in winter, while in the latter it decreased." It is concluded that reactivity to stressors is weakened during the summer. In rats with the highest index of dominance, plasma corticosterone levels were particularly low during the winter.

Morimoto, T., Shiraki, K., Asayama, M.: "Seasonal difference in responses of body fluids to heat stress." *Jap. J. Physiol.* **24**: 249-262 (1974). J15,690/74

Simon, N., Reinboth, R.: "Adenohypophyse und Hypothalamus. Histophysiologische Untersuchungen bei Lepomis (Centrarchidae)" (Adenohypophysis and hypothalamus. Histophysiologic studies on the Lepomis [Centrarchidae]). *Advanc. Anat. Embryol. Cell Biol.* **48**: 1-82 (1974).

J15,761/74

Monograph on the hypothalamus-hypophyseal system of a teleost (*Centrarchidae*) with respect to its anatomy and function under normal conditions, and after various hormone treatments or surgical interventions. Special attention is given to the identification of nerve centers and anterior pituitary cells responsible for the selective secretion of diverse adenohypophyseal hormones, as well as to changes in the pituitary during the annual reproductive cycle and its responsiveness to prolongation of the daily light period (about 160 refs.).

Hibernation

The changes characteristic of hibernation in the hedgehog have been compared to those of the G.A.S. Corresponding studies have also been performed on hamsters, bats, ground squirrels and toads, as well as on guinea pigs during "artificial hibernation." Adrenal hyperactivity is usually most pronounced at arousal and least marked during profound sleep, at which time a significant decrease in brain NEP has also been interpreted as a reflection of hypofunction in the central and sympathetic systems. The turnover of labeled NEP is reduced in most tissues, but particularly in the brain, of hibernating ground squirrels.

Hibernation

(See also our earlier stress monographs, p. xiii)

Suomalainen, P.: "Further investigations

on the physiology of hibernation." *Proc. Finn. Acad. Sci.* 131-144 (1953).

C852/53

The changes characteristic of hibernation in the hedgehog are compared to those of the

G.A.S. Relationships between these two phenomena are discussed.

Raths, P., Schulze, W.: "Die Nebennieren des Goldhamsters im Winterschlaf und bei anderen Aktivitätszuständen" (The adrenals of the golden hamster during hibernation and other activities). *Z. Biol.* **109**: 233-243 (1957). C36,859/57

Detailed description of histologic changes in the adrenal medulla and cortex of the golden hamster during hibernation, awakening from hibernation and during anesthesia induced by cold.

Vašků, J.: "Die Beeinflussung der experimentellen diphtherischen Intoxikation durch den künstlichen Winterschlaf" (The influence of artificial hibernation on experimental diphtheria intoxication). *Z. Gesamte. Inn. Med.* **16**: 885-894 (1961). D80,395/61

Hibernation did not protect guinea pigs against the adrenal changes elicited by diphtheria toxins, but it did increase their sensitivity as indicated by a rise in mortality. The "artificial hibernation" (drugs plus cold) used in these experiments acted as a stressor.

Krutzsch, P. H., Hess, M.: "Studies on the ascorbic acid content of the adrenal of the bat (*Myotis lucifugus*)."*Endocrinology* **69**: 664-666 (1961). D10,630/61

In the bat, captivity *per se* did not influence the vitamin C content of the adrenals during hibernation. "The most marked depletion of the adrenal vitamin occurred in the non-captive hibernating bats stressed by arousal, a finding well correlated with the blood corticosterone content reported for the hamster, another hibernating species, after similar treatment." Less pronounced effects were shown by ACTH in hibernating and by EP in active animals. Thus the bat responds to stress essentially like most other species—at least with regard to the parameters examined.

Uuspää, V. J.: "The catecholamine content of the brain and heart of the hedgehog (*Erinaceus europaeus*) during hibernation and in an active state." *Ann. Med. Exp. Biol. Fenn.* **41**: 340-348 (1963). E36,407/63

In the hedgehog, the brain NEP concentration decreases markedly during hibernation, whereas EP and dopamine levels show comparatively little change. The drop in NEP is interpreted as reflecting a hypofunction of the central sympathetic system.

Draskóczy, P. R., Lyman, C. P.: "Turnover of catecholamines (CA) during hiberna-

tion" (abstracted). *Pharmacologist* **7**: 167 (1965). J8,151/65

In hibernating ground squirrels, the turnover rate of labeled NEP and EP was greatly reduced in most tissues, particularly within the brain.

Canguilhem, B., Bloch, R.: "Evolution saisonnière de l'élimination des hormones surréaliennes chez un hibernant, *Cricetus cricetus*" (Seasonal evolution of adrenal hormone excretion in the hibernating animal, *Cricetus cricetus*). *Arch. Sci. Physiol. (Paris)* **21**: 27-44 (1967). G46,415/67

In the hamster (*Cricetus cricetus*), no seasonal variations in catecholamine output are noted, although such excretion diminishes during adaptation to cold and may last four months even if the animals are placed into surroundings with normal room temperature (23°C). On the other hand, urinary glucocorticoid and aldosterone excretion is subject to definite seasonal changes that are independent of ambient temperature.

Mukherji, M.: "Adrenal cortex in stress and hibernation; a histochemical study in toad (*Bufo melanostictus*)."*Acta Histochem. (Jena)* **29**: 297-303 (1968). F98,729/68

Under ordinary conditions, various stressors (cold, acute dehydration) and ACTH caused depletion of adrenocortical lipids in the toad, but during hibernation the adrenal responded only to dehydration shock.

Romita, G., Montesano, R.: "Aspetti istochimici ed ultrastrutturali delle ghiandole surrenali di Chiropteri durante l'ibernazione, il risveglio ed il periodo estivo" (Histochemical and ultrastructural aspects of adrenal glands in Chiroptera during hibernation, awakening, and the summer period). *Ateneo Parmense [Acta Biomed.]* **43**: 211-235 (1972).

J1,213/72

Detailed description of the histochemical and EM changes in the adrenals of bats, especially with regard to the effects of hibernation. In the adrenal medulla, two types of cells have been differentiated, one synthesized in EP, the other in NEP. "During the winter lethargy a depressed secretory activity has been noticed in the cells of the glomerulosa and moreover a remarkable secretion in the cells of both fasciculata and reticularis. Such activity increased after the awakening and became normal during the summer, demonstrating a tendency to store lipid droplets" (57 refs.).

Meteorologic Influences

(See also Relocation and Travel, Seasonal Variations, Hypoxia--mountaineering)

Numerous studies have dealt with the stressor effects of solar eruptions, magnetism, various types of cosmic rays and other meteorologic factors.

Special attention has been given to certain hot dry winds of Israel called *sharav*, which are similar to the African *khamsin* or *sharkiye* and the European *sirocco* and *Föhn*. They are known by many other names in different countries. Weather-sensitive people can react with an "irritation syndrome" (ascribed to 5-HT overproduction), various types of hyperthyroidism, or an "adrenal exhaustion syndrome" attributed to catecholamine deficiency. These winds cause a wide range of psychologic and somatic disturbances. Despite certain variations in the symptomatology elicited, they all tend to produce migraine headache, cardiac infarcts, changes in mood, predisposition to automobile accidents, loss of sodium, increased corticoid excretion and alterations in catecholamine and 5-HT metabolism.

Meteorologic Influences

(See also our earlier stress monographs, p. xiii, and cf. Catastrophe, Accidents)

Poumailloux, M.: "Ripercussioni umane dell'attività solare interna" (Effects of internal solar activity upon humans). *Minerva Med.* **61**: 5809-5823 (1970). H35,900/70

Theoretical considerations on the stressor effects of meteorologic factors (solar eruptions, magnetism, various types of cosmic rays).

Sulman, F. G., Danon, A., Pfeifer, Y., Tal, E., Weller, C. P.: "Urinalysis of patients suffering from climatic heat stress (Sharav)." *Int. J. Biometeorol.* **14**: 45-53 (1970).

J2,004/70

The hot dry wind ("Sharav" in Israel) tends to elicit discomfort, headaches, irritability and exacerbation of respiratory ailments in weather-sensitive people. On the basis of urinalysis, three patterns are distinguished: "serotonin hypersecretion causing a general 'Irritation Syndrome,' catecholamine deficiency resulting in the 'Exhaustion Syndrome,' histamine and creatinine overproduction combined with clinical 'Hyperthyroidism-Forme Fruste'."

Sulman, F. G.: "Meteorologische Frontverschiebung und Wetterföhligkeit: Föhn-Chamssin-Scharaw" (Sensitivity to movements of the meteorologic front). *Ärztlt. Prax.* **23**: 998-999 (1971).

J2,003/71

Certain movements of the meteorologic front produce curious psychic and somatic

phenomena which are said to be related to the G.A.S. These winds and associated weather constellations have different names and are probably not due to identical meteorologic phenomena. They are called Chamssin or Sharav (Israel), Sharkije (Egypt), Föhn (Siberia, Germany), Sirocco (Italy), Levante (Spain), Xlokk (Malta), Santa Ana Winds (California), Arizona Winds (Arizona), Zonda (Argentina), Thar-Winds (Rajasthan, New Delhi, Agra, India), Northern Winds (Melbourne) and Chinook (Canada). Despite certain differences, they elicit similar results: migraine headache, cardiac infarct, changes in mood, predisposition to automobile accidents, loss of sodium, increased excretion of glucocorticoids, diminution of 17-KS elimination and so on. Studies during Föhn showed three groups of derangements: (1) depletion of catecholamines with increasingly intense exhaustion, hypotension, fatigue, apathy, depression; (2) altered 5-HT production, especially one or two days before Föhn when ionization of the air is common, and (3) symptoms of hyperthyroidism.

Sulman, F. G., Pfeifer, Y., Superstine, E.: "Adrenal medullary exhaustion from tropical winds and its management." *Isr. J. Med. Sci.* **9**: 1022-1027 (1973). H77,285/73

The hot dry winds of Israel called Sharav are similar to the African Khamsin or Sharkije and the European Sirocco and Föhn. In weather-sensitive patients, the Sharav can elicit three different reactions: "1) 'irritation syndrome' (serotonin overproduction), 2) 'thyroid syndrome' (hyper-

thyroidism 'forme fruste'), and 3) 'adrenal exhaustion syndrome' (catecholamine deficiency.) These tropical winds cause many psychologic and somatic disturbances as well as changes in catecholamine, corticoid and 5-HT production and metabolism which are thought to be related to the various stages of the G.A.S. Therapeutic measures, including MAO blockers, restore urinary catecholamine levels.

Ohno, Y., Aoki, N., Horibe, H., Hayakawa, N., Okada, H.: "Biometeorologic studies on cerebrovascular diseases. V. A multivariate analysis of meteorologic effects on cerebrovascular accident." *Jap. Circ. J.* **38**: 195-208 (1974). H88,883/74

Review on meteorologic factors that can participate in the precipitation of cerebrovascular accidents.

Simpson, J. A.: "Weather and myasthenic fatigue." *Lancet* August 24, 1974, pp. 458-459. H90,770/74

"The myasthenic patient responded unfavourably to extremes of cold or heat (especially a hot bath or a stuffy atmosphere)

in the same way as to emotional stress." Numerous other observations indicate that meteorologic conditions, particularly changes in the weather, aggravate myasthenic weakness.

Tramp, S. W.: "The possible effect of meteorological stress on cancer and its importance for psychosomatic cancer research." *Experientia* **30**: 1474-1478 (1974).

H98,793/74

Personal observations and a review of the literature allegedly "confirm the effect of meteorological stresses (in particular thermal stresses) on thermoregulatory processes and cancer development. The similarity in physiological processes during meteorological and psychological stresses may facilitate the studies on the influence of psychosomatic factors on cancer."

Josimovic, I. B.: "Zur Wetterföhligkeit der Ulkuskranken" (Climatic sensitivity in patients with peptic ulcers). *Med. Welt* **26**: 374-376 (1975). J23,813/75

Review on the relationship between the G.A.S. and meteorologic conditions in man.

OCCUPATION

(See also Agents—athletics)

In the following section, we shall discuss the stress associated with certain occupations, such as aerospace travel; parachute jumping; air traffic control; navy, marine, and submarine diving (including underwater demolition); military service and combat; automobile driving; executive work (particularly business management and finance); medicine, dentistry and nursing; law; jobs involving shift work, and the telephone and telegraph industries; as well as a variety of other less common occupations.

Of course, these categories overlap a great deal. For example, civilian and military aerospace problems are discussed conjointly, as is military service in peace or war. However, to avoid excessive repetition (such as bombing attacks involving civilian as well as military populations), the reader is referred to the section, Catastrophe, Accidents, and for the stresses endured by POWs, to Concentration Camps.

Even if these categories—like most others in this treatise—are somewhat artificial, they will considerably accelerate the finding of literature on certain subjects.

Aerospace

Generalities. As an introduction to the various problems posed by aerospace medicine, it may be helpful to peruse some of the reviews listed in the following abstract

section. They deal with generalities of stress in aviation and space travel in relation to the G.A.S., irrespective of the particular specific effects of the task. As far as they specially concern aerospace medicine, some consideration is also given to "stress tests," interpersonal relations, immobilization, isolation, noise, vibration, hypoxia, gravity forces, sound, sonic booms, compression and decompression, temperature variations, pilot fatigue, desynchronization during flights through various time zones, and so on. However, more detailed information concerning each of these subjects is found in the corresponding special sections.

→**Stress Tests.** In selecting crews for planes or spaceships, it is naturally of the utmost practical importance to develop meaningful tests to determine—as accurately and objectively as possible—the suitability of candidates in terms of their ability to withstand the stresses of all the physical and mental demands made by this kind of work. The tests include exposure to simulated flight conditions and measurement not only of performance in properly selected perceptual-motor tasks but also of physical and mental responses, as well as analysis of circulation, pulse rate, ECG, and GSR by more complex systems, such as the "stressalyzer."

In this regard, it will also be useful to consult the special discussion on Stress Tests in the section on the functional characteristics of stress in general, since many of these are applicable to aerospace problems, although they were primarily designed to measure resistance to any kind of stressor.

→**Nervous System.** In civilian and military aviation, as in space travel, the most important causes and results of stress are neuropsychologic disturbances. These also play a principal role in determining efficiency of performance. Hence, virtually all investigations concerned with aeromedicine give prominent attention to the functions of the central and autonomic nervous systems, even if their primary objective is the measurement of some chemical change, the blood count, cardiovascular reactions, GSR or alterations in disease susceptibility.

Extensive studies in England during World War II showed that after repeated missions over enemy territory the initial extreme anxiety of pilots gradually subsided, but eventually their adaptation broke down and they developed a variety of neurotic manifestations. Here we have another example of the triphasic nature of the G.A.S. in that the initial alarm reaction is followed by the stage of resistance and eventually by that of exhaustion. For this reason, even the most courageous and even-minded fighters could perform well for only a limited number of sorties, until their "adaptation energy" was exhausted.

Undoubtedly, not only anxiety but various sensory stimuli can play a part in producing breakdown or "pilot fatigue" following demanding missions. In one interesting experiment, it was observed that deaf persons with vestibular defects who accompanied experienced pilots on acrobatic flights, failed to show the usual increase in corticoid and catecholamine production, presumably because of their impaired sense of equilibrium and hearing.

In general, those men who broke down rapidly under the strain of aerial warfare and who tended to suffer from gastrointestinal disturbances, extreme anxiety or even fainting, would not have done so under peacetime conditions. However, in predisposed individuals, the strain of battle was more likely to bring out latent tendencies than would the stressors of daily civilian life.

→**Corticoids and 17-KS.** Gluco- and mineralocorticoids as well as their metabolites are discussed conjointly with 17-KS, although the latter may be indicative either of corticoids or testoids. In general, it can be said that the stress of life is associated with an increase in the blood level and urinary elimination of corticoids and their degradation products. Such a rise may be seen even under simulated flight conditions. It is frequently associated with diuresis and other typical signs of stress, such as an elevation of catecholamine production, eosinopenia and so on. On long-distance flights, desynchronization may aggravate these changes. The effects of flying upon aldosterone excretion are less clearcut.

→**Epinephrine and Norepinephrine.** In both military and civilian pilots, catecholamine excretion is enhanced during flights as compared to levels on the ground. The findings of various investigators differ with regard to the relative predominance of EP or NEP production, which is presumably dependent upon hitherto unidentified conditioning factors. There is good reason to believe that, in addition to nervous tension, cold and gravity forces play a role here.

In air tanker pilots flying short missions over forest fires, urinary catecholamine and corticoid excretion, heart rate and ECG exhibited no evidence of significant stress. However, during emergencies, the heart rate nearly doubled.

On long flights or repeated shorter flights during six-day missions, urinary EP excretion was always increased, but other endocrine metabolic functions varied considerably. East- and west-bound earth circling missions did not induce essentially different degrees of stress, as judged by these indicators. Naval aviators practicing perilous landings on aircraft carriers showed considerable rises in the urinary elimination of 3-methoxy-4-hydroxyphenylglycol (MHPG), a catecholamine metabolite. These findings were thought to possibly indicate an accelerated metabolism of brain NEP. In inexperienced pilots, the urinary excretion of EP and NEP was not directly proportional to the length of the flight, but increased considerably during landing at unfamiliar airports.

In flight crews on fifty-four-hour bi- or tri-directional transmeridian missions, urinary catecholamine and corticoid output showed rhythmic circadian variations corresponding to the home base of the crew, even after several time zones had been traversed.

→**5-HT and Histamine.** In various species of animals travelling on satellite spaceships, the blood 5-HT level diminished.

Both 5-HT and histamine-diaminioxidase activity in the blood of astronauts showed circadian variations which might play an important role in space medicine.

→**Metabolites.** Pilots under training may exhibit eosinopenia with decreased blood *glutathione* levels at times of stress, but *hippuric acid* formation is not affected. There is some evidence that simulated flights may alter serum *cholesterol phospholipid* and *lipoprotein* concentrations. In pilots flying six-hour over-water missions, *corticoid* levels were increased in plasma but not in urine. Urinary *EP*, *NEP*, *urea* and *uric acid* values were greatly elevated. Allegedly, *hypoglycemia* and *insulin* hypersensitivity may occur in pilots suffering malaise.

The metabolic responses of astronauts on a two-week orbital space flight showed considerable individual variations. In only one of the two participants was there a significant rise in urinary *calcium* during the second week of the flight, but urinary

phosphate elimination increased in both subjects. Some data were also registered on urinary *nitrogen, sulfate, magnesium, sodium, potassium* and *chlorine* in relation to corticoid secretion, but the small number of available observations does not permit far-reaching conclusions.

→**Blood Count.** Operating a pursuit meter, flying and exposure to heat increased 17-KS excretion and caused eosinopenia in normal, but allegedly, not in schizophrenic individuals.

→**Cardiovascular System.** In pilots performing stressful flying exercises for the first time, blood pressure rose consistently, but pulse rate was found to be variable and sometimes actually decreased. There was also pallor, tremor, flushing and excessive sweating. In most instances, tachycardia is noted in conventional aircraft and helicopter pilots during flight.

As astronauts reach weightlessness after takeoff, they exhibit polyuria, and have the illusion of standing on their heads because of increased blood supply to the brain.

→**Varia.** Flying, especially on combat missions, may aggravate preexistent diabetes or elicit an Addisonian syndrome.

A β -adrenergic blocking agent, propranolol, tends to inhibit the cardiovascular changes characteristic of simulated flights or intense muscular exercise.

G42,395/66

An attempt to evaluate resistance to fatigue using blood circulation, pulse rate, ECG, oral temperature and motor coordination as indices.

Ruff, G. E., Korchin, S. J.: "Adaptive stress behavior." In: Appley, M. H. and Trumbull, R., *Psychological Stress. Issues in Research*, pp. 297-323. New York: Appleton-Century-Crofts, 1967.
E10,417/67

Studies on Mercury astronauts showed "the effectiveness of adaptive responses based on past experience and professional competence. Given a group of men with repeated success in accomplishment of hazardous duties, followed by training which led to

highly organized, efficient patterns of behavior, evidence of disruptive stress behavior was minimal."

Pearson, D. W., Thackray, R. I.: *Consistency of Performance Change and Autonomic Response as a Function of Expressed Attitude toward a Specific Stress Situation*. Federal Aviation Administration, Aviation Med. pamphlet, p. 7. Washington, D. C., 1969. G71,477/69

Comparative studies on fearful and confident pilots performing standard tasks under the threat of receiving electric shocks as a punishment for errors. Half of the subjects were assigned perceptual-motor tasks, others cognitive-interference tasks. The "results indicate significant differences between groups in both sets of measures and support the hypothesis that attitude questionnaires may be used to predict performance and bodily responses to specific stress situations."

Iampietro, P. F., Melton, C. E. Jr., Higgins, E. A., Vaughan, J. A., Hoffmann, S. M., Funkhouser, G. E., Saldivar, J. T.: *High Temperature and Performance in a Flight Task Simulator*. Federal Aviation Administration, Aviation Med. pamphlet, p. 8. Washington, D.C., 1972. G91,965/72

In a flight task simulator, performance definitely declined at high cockpit temperatures. Relationships to the classic manifestations of the stress syndrome are not discussed.

Smith, R. C.: *A Study of the State-Trait Anxiety Inventory and the Assessment of Stress Under Simulated Conditions*. Federal Aviation Administration, Aviation Med. pamphlet, p. 5. Washington, D.C., 1972. G96,466/72

The STAI "produces scores indicating the individual's current level of anxiety, i.e., A-State, and how prone the individual is to experience anxiety, i.e., A-Trait. It is easily administered and scored and, since it contains only 40 items which are to be rated on four-point scales, it takes only a few minutes for the respondent to complete." Its possible use in the study of aviation stress is examined. "It appears that the STAI can be used for measuring the anxiety of air traffic controllers, or workers in other high-demand occupations, with considerable confidence that the validity of findings will not be reduced by the unsuspected effects of biasing response sets."

Sommer, H. C., Harris, C. S.: "Combined effects of noise and vibration on human tracking performance and response time." *Aerosp. Med.* **44**: 276-280 (1973).

H81,610/73

Thackray, R. I., Rylander, R., Touchstone, R. M.: *Sonic Boom Startle Effects. Report of a Field Study*. Federal Aviation Administration, Aviation Med. pamphlet, p. 16. Washington, D.C., 1973. J10,440/73

Review and personal observations on the effects of simulated and real sonic booms upon the "startle response," which measures arm-hand steadiness (11 refs.).

Buck, L., Leonardo, R.: *Sleep Patterns and Psychomotor Performance of Aircrew Flying the North Pacific*. National Research Council, Division Mech. Eng. Report No. LTR-CS-97, p. 22. Ottawa, 1973. J10,491/73

Preliminary data on the stress endured by aircrews flying the North Pacific route from Vancouver to Tokyo as measured by the "stressalyzer." This is an instrument permitting objective assessment of a step-tracking task in which the subject pursues a light as it moves between five horizontally-aligned positions. "The task is subject-paced, target movement depending on pointer alignment, and the coupling between control wheel and pursuit pointer is inverse, the two moving in opposite directions. The instrument yields a number of performance indices relating to the speed and accuracy of decision and movement." Because of various technical difficulties, the application of the machine to this particular task did not provide definitive results.

Strasser, H., Brilling, G., Klinger, K. P., Müller-Limmroth, W.: "Physiological and operational state of a group of aeroplane pilots under the conditions of stressing tracking tests." *Aerosp. Med.* **44**: 1040-1047 (1973). J11,374/73

→ **Nervous System.** McFarland, R. A.: "Fatigue in aircraft pilots." *N. Eng. J. Med.* **225**: 845-855 (1941). B34,718/41

General discussion of the literature on "pilot fatigue" (34 refs.).

Symonds, C. P.: "The human response to flying stress. Lecture I: Neurosis in flying personnel." *Br. Med. J.* December 4, 1943, pp. 703-706. B26,422/43

Symonds, C. P.: "Lecture II. The foundations of confidence." *Br. Med. J.* December 11, 1943, pp. 740-744. B26,422/43

General description of flying stress in Royal Air Force personnel during World War II. Among the most striking manifestations are fatigue, impairment of skill, vision and hearing, gastrointestinal disorders and gradually increasing anxiety.

Bond, D. D.: *How Can the Flight Surgeon Better Treat Anxiety?* pp. 19-23. Report No. 2 to the Air Surgeon, U.S. Army Air Forces by The Josiah Macy, Jr. Foundation. New York, 1945. B40,066/45

Reid, D. D.: "Some measures of the effect of operational stress on bomber crews." *Air Ministry, A.P.* 3139, pp. 245-258. London: HMSO, 1947. B27,155/47

Reid, D. D.: "Fluctuations in navigator performance during operational sorties." *Air Ministry, A.P.* 3139, pp. 321-329. London: HMSO, 1947. B27,164/47

Pilots making repeated sorties over Germany during World War II showed an initial intense anticipatory anxiety with steady deterioration in efficiency on the outward journey, particularly over the enemy coast and on approaching the target. This was maximal in the phase of heavy enemy fighter opposition and persisted as long as the aircraft was over enemy territory. Following numerous sorties, neurotic manifestations and breakdown eventually occurred.

Kahn, L. A.: "A discussion of some causes of operational fatigue in the Army Air Forces." *Psychol. Bull.* 44: 34-53 (1947). B40,068/47

Review on operational fatigue in the Air Force, especially under combat conditions. Undoubtedly, predisposition plays a major role but "clearly, the literature indicates that those men who did break under the strain of battle would in a majority of cases not have done so under the conditions of peace-time living" (12 refs.).

Anderson, R. C.: "The motivations of the flyer and his reactions to the stresses of flight." *J. Aviat. Med.* 18, Sect. 2, Supp.: 18-30 (1947). B26,773/47

Reid, D. D.: "Sickness and stress in operational flying." *Br. J. Soc. Med.* 2: 123-131 (1948). B26,739/48

Field studies in the Bomber Command of the Royal Air Force during World War II suggest that "the acute anxiety caused by a high casualty rate had a much more decisive effect on health and morale than had prolonged or intensive operational effort.

Operational inexperience which also plays a part in determining the incidence of neurosis, is shown to be relevant in the prognosis of cases of sickness occurring in conditions of acute stress on operational sorties." Fainting and other symptoms attributed to the nervous and alimentary systems, especially if they occurred soon after takeoff, were indicative of impending breakdown.

Sem-Jacobsen, C. W.: "Electroencephalographic study of pilot stresses in flight." *Aerosp. Med.* 30: 797-801 (1959).

C77,977/59

Tobias, P. R.: "The effects of radiation on integrated behavior." In: Burns, N. M., Chambers, R. M. et al., *Unusual Environments and Human Behavior*, pp. 395-417. Glencoe, Ill.: Free Press, 1963. E10,434/63

Review on the effects of various intensities of x-irradiation upon the behavior of animals and man, with special reference to aerospace medicine.

Rotondo, G.: "Considerazioni cliniche e medico-legali su una sindrome addisoniana manifestatasi in un pilota militare dopo lunga ed impegnativa attività di volo" (Clinical and medico-legal considerations on an Addisonian syndrome appearing in a military pilot after long and stressful flying activity). *Riv. Med. Aeronaut. Spaz.* 26: 291-306 (1963). E24,219/63

The development of an Addisonian syndrome is ascribed to exhaustion of the adrenals due to pilot's fatigue.

Jongbloed, J.: "Medische vraagstukken in verband met de ruimtevaart. VII. De psychische belasting van de ruimtevaarder" (Medical problems connected with space travel. VII. The psychic stress in the spaceship traveller). *Med. Tijdschr. Geneeskhd.* 107: 1188-1190 (1963) (Dutch). J23,561/63

Rotondo, G.: "Sull'impiego dell'acido adenozintrifosforico e della cocarbossilasi in piloti affetti da lieve o iniziale fatica di volo" (The use of ATP and cocarboxylase in pilots suffering from light or initial flying fatigue). *Riv. Med. Aeronaut. Spaz.* 27: 176-192 (1964). G19,344/64

Flying fatigue in jet pilots, ascribed to the exhaustion of adaptation energy, was effectively treated by oral medications containing ATP and cocarboxylase (19 refs.).

Barron, C. I., Dreher, J. J.: "Effects of electric fields and negative ion concentrations on test pilots." *Aerosp. Med.* **35**: 20-23 (1964). G37,107/64

The results of a study on pilots exposed to ionic or electric fields "neither support nor negate the hypothesis that negative ions or ions plus electric fields may be beneficial in ameliorating the effects of fatigue or stress."

Balke, B., Melton, C. E. Jr., Blake, C.: "Physiological stress and fatigue in aerial missions for the control of forest fires." *Aerosp. Med.* **37**: 221-227 (1966).

G37,796/66

Rotondo, G.: "Contributo sperimentale al trattamento terapeutico e preventivo della fatiga del pilotaggio" (Therapeutic and preventive treatment of pilot fatigue. Experimental contribution). *Riv. Med. Aeronaut. Spaz.* **32**: 231-268 (1969). H18,349/69

Pilot fatigue is compared with the stage of exhaustion of the G.A.S., and presumably is due to depletion of adaptation energy. Allegedly, dehydroisoandrosterone exerts beneficial effects.

Baruch, D.: "Some medical aspects in agricultural flights relating to fatigue among agricultural pilots." *Aerosp. Med.* **41**: 447-450 (1970). G36,975/70

A study in Israel showed that "as a result of agricultural flights under hard weather conditions there were significant changes in the pilot's body such as loss of weight, increase of body temperature, decrease of eosinophil cells, tendency to decrease of blood sugar level. All these changes in combination with lack of sleep may reduce the alertness of the pilot and may be considered an important factor in aircraft accidents in agricultural flights."

Yanowitch, R. E., Mohler, S. R., Nichols, E. A.: "Psychosocial reconstruction inventory: a postdictal instrument in aircraft accident investigation." *Aerosp. Med.* **43**: 551-554 (1972). J14,847/72

Review of data on the role of stress in increasing accident proneness, especially in pilots.

Yanowitch, R. E., Bergin, J. M.: *The Aircraft as an Instrument of Self Destruction*. Federal Aviation Administration, Aviation

Med. pamphlet, p. 5. Washington, D.C., 1973. J5,009/73

Psychologic study suggesting that pilot fatigue, especially if combined with other chronic stressors (for example, family problems), may influence the pilot's behavior so that he provokes a fatal accident for suicidal reasons.

→Corticoids and 17-KS. Pincus, G., Hoagland, H.: "Steroid excretion and the stress of flying." *J. Aviat. Med.* **14**: 173-193 (1943). 84,492/43

Increased urinary 17-KS excretion and diuresis were noted in subjects shown to be fatigued on the "Steven's serial coordination meter, the Hoagland-Werthessen pursuit meter or [in] pilots on test flights or instruction flights." As altitude increased, the response on the Hoagland-Werthessen pursuit meter was associated with poorer performance, owing to reduced oxygen tension. Presumably, "the simulated and actual stress of flying studied induces adrenal steroid hormone hypersecretion that is reflected in the 17-ketosteroid output; this hypersecretion either causes or is accompanied by diuresis."

Craven, C. W., Smith, C. S.: "Steroid excretion in airmen under stress." *J. Aviat. Med.* **26**: 200-205; 213 (1955) (22 refs.). C16,180/55

Marchbanks, V. H.: "Effect of flying stress on urinary 17-hydroxycorticosteroid levels. Observations during a 22 1/2-hour mission." *J. Aviat. Med.* **29**: 676-682 (1958). C58,431/58

Urinary steroids were increased almost twofold in the pilot of a B-52 aircraft on a 22.5 hour nonstop flight from Florida to Argentina to New York. "The 17-OHCS urinary output is a favorable index for measuring stress in flying personnel."

Hale, H. B., Ellis, J. P. Jr., Kratochvil, C. H.: "Effects of piloting supersonic aircraft on plasma corticosteroids and bicarbonate." *J. Appl. Physiol.* **14**: 629-631 (1959). J11,140/59

In pilots flying supersonic military aircraft, no significant correlation was found between the fall in plasma bicarbonate and the rise in corticoids.

Marchbanks, V. H. Jr.: "Flying stress and urinary 17-hydroxycorticosteroid levels during twenty-hour missions." *Aerosp. Med.* **31**: 639-643 (1960). C90,270/60

In B-52 crew members, the highest in-

crease in urinary 17-OHCS output occurred during missions flown at a time most out of phase with the normal sleep cycle. This excretion is regarded "as a favorable index for evaluation of stress in flying personnel."

Bugard, P.: "Etude hormonale et métabolique de la fatigue. II. Personnel volant à bord d'avions intercontinentaux" (Hormonal and metabolic study of fatigue. II. Crew members on transcontinental flights). *Ann. Endocrinol.* (Paris) **22**: 1008-1016 (1961).

D22,366/61

Hyperaldosteronism was more pronounced on jets than on conventional aircraft, and was definitely related to emotional tension. A decrease in 17-KS was evident in men, but not in women. Excretion of 17-OHCS and creatinine was increased. Allegedly, endocrine-metabolic examinations can provide valuable early indices of fatigue among aviators.

Ulvedal, F., Smith, W. R., Welch, B. E.: "Steroid and catecholamine studies on pilots during prolonged experiments in a space cabin simulator." *J. Appl. Physiol.* **18**: 1257-1263 (1963).

E35,063/63

In pilots placed in a space cabin simulator for several weeks, the corticoid and catecholamine variations were no more severe than those caused by extensive medical examinations. "The only significant trend was the continuous linear increase in the excretion of corticosterone-like hormones. There were borderline indications that the excretion of 17-hydroxycorticosteroids and norepinephrine was altitude dependent. Extraordinary occurrences in the simulator were correlated with increased catecholamine and steroid excretion." The space cabin simulator is described in detail.

Marchbanks, V. H. Jr., Hale, H. B., Ellis, J. P. Jr.: "Stress responses of pilots flying 6-hour overwater missions in F-100 and F-104 aircraft." *Aerosp. Med.* **34**: 15-18 (1963).

G2,360/63

In navy pilots flying six-hour overwater missions in F-100 and F-104 aircraft, corticoid levels were increased in the plasma but not in urine. EP and NEP values were considerably above normal, as were the excretion rates of urea and uric acid, while phosphate levels were not altered. The total reaction depended very much upon airplane characteristics and pilot experience.

Colehour, J. K., Graybiel, A.: "Excretion of 17-hydroxycorticosteroids, catechol amines,

and uropepsin in the urine of normal persons and deaf subjects with bilateral vestibular defects following acrobatic flight stress." *Aerosp. Med.* **35**: 370-373 (1964).

G11,705/64

Deaf persons with vestibular defects who accompanied experienced pilots on acrobatic flights failed to show the usual increase in corticoids and catecholamines, presumably because their appropriate sensory organs in the inner ear were not functional.

Litta-Modignani, R., Magid, E. B., Blivais, B. B.: "Effects of whole body vibrations of humans on plasmatic and urinary corticosteroid levels." In: Martini, L. and Pecile, A., *Hormonal Steroids. Biochemistry, Pharmacology, and Therapeutics*, Vol. 2, pp. 517-525. New York and London: Academic Press, 1965.

E5,496/65

In man, vibrations of a sinusoidal nature performed by a mechanical shake table that attempts to imitate conditions in a jet aircraft seat, did not cause any increase in plasma 17-OHCS, but rather a small decrease. A slight diminution was also found in urinary blue-tetrazolium-reducing steroids (BTS) and 17-KGS. Under these conditions of moderate vibration, "a mild inhibition of the hypothalamic-hypophysis-adrenal axis could have occurred."

Hale, H. B.: "Plasma corticosteroid changes during space-equivalent decompression in partial-pressure suits and in supersonic flight." In: Martini, L. and Pecile, A., *Hormonal Steroids. Biochemistry, Pharmacology, and Therapeutics*, Vol. 2, pp. 527-534. New York and London: Academic Press, 1965.

E5,497/65

In pilots, decompression to space-equivalent pressure levels in partial-pressure suits caused varying degrees of increase in plasma corticosteroids. However, "on the average, plasma cortisol concentrations, after extreme decompression in these suits, reached levels similar to those observed in human subjects reacting to hypoxia in combination with heat or flying high-performance aircraft."

Elmadjian, F., Forchielli, E.: "Characterization of hormonal steroids of the chimpanzee: changes observed in adrenal cortical function during simulated and actual space flight." In: Martini, L. and Pecile, A., *Hormonal Steroids. Biochemistry, Pharmacology, and Therapeutics*, Vol. 2, pp. 535-544. New York and London: Academic Press, 1965.

E5,498/65

Detailed report on changes in the urinary excretion and blood levels of various steroids (corticoids, estrogens, androgens and so on) in chimpanzees during actual or simulated space flights. "Interpretation of the above data is difficult due to the varying degrees of time-lapse from the point of termination of the stress to the time of sampling."

Jovy, D., Brüner, H., Klein, K. E., Wegmann, H. M.: "Adaptive responses of adrenal cortex to some environmental stressors, exercise and acceleration." In: Martini, L. and Pecile, A., *Hormonal Steroids. Biochemistry, Pharmacology, and Therapeutics*, Vol. 2, pp. 545-553. New York and London: Academic Press, 1965. E5,499/65

Plasma corticoid and eosinophil determinations in healthy young men exposed to several stressors encountered during space flights (hypoxia, cold, heat, acceleration, muscular work). The results of exposure to these stressors, alone or in various combinations, are taken as an expression of individual sensitivity to stress, and offer a criterion of practical importance.

Ulvedal, F., Roberts, J. J.: "Study of man during a 56-day exposure to an oxygen-helium atmosphere at 258 mm. Hg total pressure. VI. Excretion of steroids and catecholamines." *Aerosp. Med.* 37: 572-578 (1966). F93,442/66

Men kept in a double-walled space cabin simulator in an oxygen-helium atmosphere showed no significant disturbance in glucocorticoid or catecholamine elimination. A reversal of the corticoid excretion rhythm was noted in subjects who slept during the day and worked at night (22 refs.).

Colehour, J. K., Graybiel, A.: "Biochemical changes occurring with adaptation to accelerative forces during rotation." *Aerosp. Med.* 37: 1205-1207 (1966). F95,358/66

Bourne, P. G., Rose, R. M., Mason, J. W.: "Urinary 17-OHCS levels. Data on seven helicopter ambulance medics in combat." *Arch. Gen. Psychiatry* 17: 104-110 (1967). G63,035/67

In seven helicopter ambulance physicians in Vietnam, "the variation in the level of 24-hour urinary 17-OHCS excretion deviates very little from the overall mean, and bears no direct relationship to whether the subjects were flying combat missions or not." It is assumed that "stress can only be defined in terms of the individual's interaction with the environment, and that man is able to make

a satisfactory psychological and physiological adaptation even to the most threatening situations."

"Stress in helicopter personnel." *J.A.M.A.* 201: 320-321 (1967). F85,752/67

Studies on helicopter ambulance crews showed that the usual stress-induced increase in urinary corticoid excretion can be remarkably well controlled by certain psychologic adjustments minimizing the reality of the danger to be faced on combat missions and exaggerating the dangers already dealt with "in order to enhance... feelings of omnipotence and invincibility."

Lafontaine, E., Lavernhe, J., Courillon, J., Medvedeff, M., Ghata, J.: "Influence of air travel east-west and vice-versa on circadian rhythms of urinary elimination of potassium and 17-hydroxycorticosteroids." *Aerosp. Med.* 38: 944-947 (1967). H3,611/67

Studies on transatlantic flight crews show that, among various metabolic parameters, 17-OHCS exhibits the clearest circadian variations. After a quick roundtrip, with twenty hours of exposure to a negative time zone change of eleven hours, the circadian rhythm of potassium and 17-OHCS immediately re-establishes concordance with the preexisting reference rhythm. With five days of exposure to a similar time zone change, the circadian eliminatory rhythm of 17-OHCS begins to adapt itself to local time on the third day and becomes complete by the fifth day, by then being the antithesis of the preestablished reference rhythm.

Lafontaine, E., Ghata, J., Lavernhe, J., Courillon, J., Bellanger, G., Laplane, R.: "Rythmes biologiques et décalages horaires. Etude expérimentale au cours de vols commerciaux long-courriers" (Biologic rhythm and time zone differences. Experimental study during long commercial flights). *Concours Méd.* 89: 3731-3746; 3963-3976 (1967). G47,151/67

On flights from Paris to Anchorage, with an eleven-hour time zone difference, there occurred a decrease in diuresis followed by a "rebound," and a disruption in the circadian rhythm of catecholamine and corticoid elimination.

Wegmann, H. M., Klein, K. E., Brüner, H.: "Die Auswirkung fliegerischer Belastung auf einige Blutkomponenten" (Effects of flying stress on certain components of the blood). *Int. Z. Angew. Physiol.* 23: 293-304 (1967). G45,957/67

Among the indicators examined in jet pilots training for Starfighter F-104 G flights, corticoids and certain enzyme activities in the blood proved most sensitive to stress, whereas other enzyme and blood sugar variations were unreliable (24 refs.).

Hale, H. B., Williams, E. W.: "Endocrine-metabolic response to sequential decompression during simulated orbital flight." *Aerosp. Med.* **39**: 1175-1177 (1968). H22,180/68

In men exposed to sequential decompression during simulated orbital flights, "non-specific stress was evident, as there were decompression-induced elevations (which were progressive with time) in creatinine, urine volume, sodium, norepinephrine, and urea. Epinephrine was also elevated, but the peak effect came at an early time. As a late effect, 17-OHCS excretion became elevated."

Miller, R. G.: "Secretion of 17-hydroxycorticosteroids (17-OHCS) in military aviators as an index of response to stress: a review." *Aerosp. Med.* **39**: 498-501 (1968).

J22,567/68

Rubin, R. T., Miller, R. G., Arthur, R. J., Clark, B. R.: "Differential adrenocortical stress responses in naval aviators during aircraft carrier landing practice." *Psychol. Rep.* **26**: 71-74 (1970).

J15,627/70

Miller, R. G., Rubin, R. T., Clark, B. R., Crawford, W. R., Arthur, R. J.: "The stress of aircraft carrier landings. I. Corticosteroid responses in naval aviators." *Psychosom. Med.* **32**: 581-588 (1970). G80,363/70

During aircraft carrier landing practice of two-man F-4B jets, U.S. Navy pilots showed considerable "adrenal cortical stress" (17-OHCS excretion), while their flight officers did not. "The complex and dangerous task of carrier landing appears to be a greater stress on the pilot in control of the aircraft than on his passive partner" (25 refs.).

Leach, C. S., Alexander, W. C., Johnson, P. C.: "Adrenal and pituitary response of the Apollo 15 crew members." *J. Clin. Endocrinol. Metab.* **35**: 642-645 (1972).

H61,627/72

"Inflight studies during the 14-day Gemini 7 mission showed increased urinary aldosterone excretion." Inflight specimens were not collected during the Apollo 15 mission, but when pre- and postflight levels were compared, the elimination of urinary aldosterone was again manifest. "Increased secretion of this hormone could be one of man's adaptations to the weightless environment."

Glusskaya, I. G., Vinogradov, L. A., Noskov, V. B., Balakhovskiy, I. S.: "Effect of hypodynamia and other spaceflight factors on the excretion of 17-hydroxycorticosteroids and aldosterone." *Kosm. Biol. Med.* **7** No. 3: 43-48 (1973).

J14,652/73

Hale, H. B., Storm, W. F., Goldzieher, J. W., Hartman, B. O., Miranda, R. E., Hosenfeld, J. M.: "Physiological cost in 36 and 48 hour simulated flights." *Aerosp. Med.* **44**: 871-881 (1973).

H95,634/73

"Physiologic cost was assessed by use of a battery of urinary techniques, including potassium, sodium, urea, 17-OHCS, and, in some cases, individual 17-ketosteroids. Comparison was made of responses to (a) uncomplicated flight, (b) flight complicated by environmental dryness, (c) flight complicated by 8,000-ft pressure altitude, and (d) flight complicated by dryness and altitude. The prolonged psychomotor effort (and attendant sleep deprivation) acted as a nonspecific stressor. Altitude had intensifying influence, but dryness tended to counteract some phases of the stress response."

Hale, H. B., Hartman, B. O., Harris, D. A., Miranda, R. E., Williams, E. W.: "Physiologic cost of prolonged double-crew flights in C-5 aircraft." *Aerosp. Med.* **44**: 999-1008 (1973).

J11,333/73

The changes in urinary elimination of EP, NEP, 17-OHCS, potassium, nitrogen, urea and creatinine on double-crew transpacific missions in C-5 military aircraft essentially confirmed earlier observations made under similar conditions in C-141 aircraft. "Recovery from these long missions (average duration = 65 hrs) involved differential reversal among the flight-affected endocrine-metabolic functions. Extrapolations of post-flight data suggest that the time for complete recovery exceeded the flight time."

Leach, C. S., Rambaut, P. C., Johnson, P. C.: "Adrenocortical responses of the Apollo 17 crew members." *Aerosp. Med.* **45**: 529-534 (1974).

J13,390/74

In Apollo 17 astronauts during their first thirteen days in space, "aldosterone excretion was normal early and elevated later in the mission, probably causing a loss in total body exchangeable potassium. There was decreased 17-hydroxycorticosteroid excretion only during the early mission days for the two moon landers and throughout the mission for the other astronaut. Cortisol excretion was elevated on physically stressful mission days.

At recovery, plasma ACTH was elevated without a similar increase in plasma cortisol."

Arslan, M., D'Amelio, G., Marchiori, C.: "Clinical and endocrinological effects of coriolis accelerations and their behavior under drug treatment." *Acta Otolaryngol.* (Stockh.) **77**: 155-158 (1974).

J12,116/74

In subjects who make head movements during a body rotation at constant angular speed, coriolis accelerations occur by provoking a flow of endolymph in the semicircular canals. This is associated with nausea, dizziness, pallor, sweating, vomiting, variations in pulse rate and arterial pressure and a considerable rise in urinary catecholamine, 17-KS and 17-OHCS elimination. The authors conclude that "for normal subjects, exposure to Coriolis accelerations represents a stress which affects the adrenergic but not the hypophysial-cortical system. This stress is consistently related to the emotional tension originated by the test itself. The possibility of preventing the adrenergic hyperactivity of emotional origin by diazepam is discussed."

Pinter, E. J.: "Metabolic and endocrine changes in aerobic flight." *Aerospace Med.* **45**: 1159-1163 (1974).

J17,132/74

→Epinephrine and Norepinephrine. Euler, U. S. von, Lundberg, U.: "Effect of flying on the epinephrine excretion in air personnel." *J. Appl. Physiol.* **6**: 551-555 (1954).

C1,706/54

In military pilots, EP excretion was about four times less during ground activity than during flight, and was lower still during sleep. Corresponding variations in NEP output were slight or nonexistent.

Klepping, J., Buisson, O., Guerrin, J., Escousse, A., Didier, J. P.: "Evaluation de l'élimination urinaire des catécholamines chez des pilotes d'avions à réaction" (Evaluation of the urinary excretion of catecholamines in jet pilots). *C.R. Soc. Biol.* (Paris) **157**: 1727-1729 (1963).

G9,483/63

In jet pilots, urinary excretion of catecholamines after a brief flight at 50,000 ft. is considerably increased. More marked augmentation alternates between EP and NEP concentrations. The response is ascribed to psychic rather than physical stressor effects.

Klepping, J., Truchot, R., Mounie, J., Eygonnet, J. P.: "Evaluation de l'élimination urinaire de l'acide 3-méthoxy-4-hydroxymandélique (VMA) chez les pilotes d'avions à

réaction au cours de vols d'entraînement de différents types" (Evaluation of the urinary elimination of 3-methoxy-4-hydroxymandelic acid [VMA] in jet pilots during different types of training flights). *C.R. Soc. Biol.* (Paris) **158**: 1815-1817 (1964).

E35,277/64

Euler, U. S. von: "Quantitation of stress by catecholamine analysis." *Clin. Pharmacol. Ther.* **5**: 398-404 (1964).

G18,238/64

Review of the literature and personal observations on man suggest that "gravitational stress and exposure to cold are mainly associated with an increase in the norepinephrine excretion, indicating the importance of this hormone in circulatory and temperature controlling homeostatic mechanisms. Mental stress involving exhilarating or aggressive reactions is also associated with an increase in the norepinephrine excretion. The types of emotional stress which are mainly characterized by apprehension, anxiety, pain, or general discomfort are regularly accompanied by an increase in the epinephrine excretion." Special sections are devoted to catecholamine excretion associated with flying, mental work and exposure to cold.

McKenzie, J. M., Fiorica, V.: *Physiological Responses of Pilots to Severe Weather Flying*. Federal Aviation Administration, Aviation Med. pamphlet, p. 8. Washington, D.C., 1966.

G44,104/66

Among the physiologic responses examined in pilots flying under very bad weather conditions, an increase in total urinary catecholamine excretion was most constant.

Melton, C. E., Wicks, M., Saldivar, J. T. Jr., Morgan, J., Vance, F. P.: *Physiological Studies on Air Tanker Pilots Flying Forest Fire Retardant Missions*. Federal Aviation Administration, Aviation Med. pamphlet, p. 10. Washington, D.C., 1968.

G67,527/68

In air tanker pilots flying forest fire retardant missions of limited length, urinary catecholamine and corticoid excretion, heart rate and ECG were used to appraise stress. "None of the measurements indicated that a significant amount of stress was involved, nor was fatigue evident. Heart rates correspond to those of sedentary workers, though doubling of heart rate occurred during two emergencies (hydraulic line failure). Heart rate followed a consistent pattern during flights with the minimums occurring on route to and from fires and maximums during retardant drops."

Hale, H. B., Anderson, C. A., Williams, E. W., Tanne, E.: "Endocrine-metabolic effects of unusually long or frequent flying missions in C-130E or C-135B aircraft." *Aerosp. Med.* **39**: 561-570 (1968). G63,855/68

"Flight-stress appraisal was made by means of a battery of urinary determinations (epinephrine, norepinephrine, 17-OHCS, urea, uric acid, phosphorus, magnesium, sodium, and potassium) for flyers who participated in (a) 20-hour missions in C-130E aircraft (flights from New Zealand to Antarctica, and back), (b) 6-day missions in C-135B aircraft (earth-circling missions) or (c) 7-week missions in C-135B aircraft (overfrequent transoceanic and transcontinental flying). The adrenal medulla (judging by urinary epinephrine) consistently showed flight-sensitivity, but other endocrine-metabolic functions varied in ways indicative of adaptation." East- and westbound earth-circling missions did not elicit essentially different degrees of flight stress, as demonstrated by the above mentioned indices.

Hale, H. B., Williams, E. W., Buckley, C. J.: "Aeromedical aspects of the first nonstop transatlantic helicopter flight: III. Endocrine-metabolic effects." *Aerosp. Med.* **40**: 718-723 (1969). G75,913/69

In the crew of the first nonstop transatlantic helicopter flight, "nonspecific stress was evident, as flight caused a 143 percent gain in epinephrine, a 25 percent gain in urea and a 51 percent reduction in the norepinephrine/epinephrine ratio. It also modified the circadian trends for 17-OHCS and phosphorus."

Debijadji, R., Perovic, L., Varagic, V.: "Evaluation of the sympatho-adrenals activity in pilots by determination of urinary catecholamines during supersonic flight." *Aerosp. Med.* **41**: 677-679 (1970). J21,924/70

Observations on supersonic pilots "indicate that stress reactions to flight conform to the General Adaptation Syndrome pattern."

Rubin, R. T., Miller, R. G., Clark, B. R., Poland, R. E., Arthur, R. J.: "The stress of aircraft carrier landings. II. 3-Methoxy-4-hydroxyphenylglycol excretion in naval aviators." *Psychosom. Med.* **32**: 589-597 (1970). G80,364/70

In naval aviators practicing landing on aircraft carriers (which causes considerable stress), the urinary excretion of 3-methoxy-4-hydroxyphenylglycol (MHPG), a catechol-

amine metabolite, increased considerably. "These findings suggest that there may be an accelerated metabolism of brain norepinephrine under conditions of heightened arousal and concentration compared to the normal waking state."

Melton, C. E., Fiorica, V.: *Physiological Responses of Low-Time Private Pilots to Cross-Country Flying*. Federal Aviation Administration, Aviation Med. pamphlet, p. 6. Washington, D.C., 1971. G85,171/71

In inexperienced private pilots, each of whom made three cross-country flights, heart rate and urinary excretion of EP and NEP did not change in proportion to the length of the flight. "However, the level of stress was high when compared to other types of flying activities. The total stress of such flights must, therefore, be considered to be in direct proportion to the length of the flights." Terminal procedures at unfamiliar airports caused the greatest increase in catecholamine excretion and "acted as rather powerful stressors of short duration compared to the duration of the entire flight."

Hale, H. B., Hartman, B. O., Harris, D. A., Williams, E. W., Miranda, R. E., Hosenfeld, J. M.: "Time zone entrainment and flight stressors as interactants." *Aerosp. Med.* **43**: 1089-1094 (1972). J2,017/72

In flight crews on fifty-four-hour bi- or tri-directional transmeridian missions, urinary corticoid and catecholamine excretion showed rhythmic variability that corresponded to the crews' home base, even after several time zones had been crossed. Corticoid and catecholamine responses to flight stressors were least pronounced at 22:00 and most marked at 06:00 Eastern Standard Time, which corresponded to home base. Essentially similar findings were obtained on fifty-hour missions.

→**5-HT and Histamine.** Parin, V. V., Antipov, V. V., Raushenbakh, M. O., Saksonov, P. P., Shashkov, V. S., Chernov, G. A.: "Changes in blood serotonin level in animals exposed to ionizing radiation and dynamic factors of space flight." *Fed. Proc.* **25**: T103-T106 (1966). F60,935/66

In various species of animals travelling in satellite-spaceships, exposure to x-rays, acceleration and vibration considerably diminished the blood 5-HT content.

Vaysfel'd, I. L., Il'icheva, R. F.: "Diurnal rhythm of the content of biogenous amines

(histamine, serotonin) in human blood under normal conditions and during altered work-sleep cycles." *Kosm. Biol. Med.* **6** No. 5: 56-62 (1972) (English translation of Russian original). H79,765/72

The histamine-diaminoxidase system shows considerable circadian variations in healthy subjects. The blood 5-HT content tends to decrease at night. Changes in the work-sleep cycle cause fluctuations in these parameters "related not only to the stressor applied, but also to the initial state of the organism." These findings are especially important in space medicine.

→**Metabolites.** Persky, H.: "Response to a life stress: evaluation of some biochemical indices." *J. Appl. Physiol.* **6**: 369-374 (1953). J11,917/53

Pilots under training were subjected to various stressors (parachute jumps, physical exercise and so on) which caused a significant diminution in blood eosinophil and *glutathione* levels, but which did not affect the synthesis of *hippuric acid* from administered sodium benzoate. "These findings are taken to indicate that airborne training focal stresses are of intermediate severity on a scale whose poles are fear of failure and fear of bodily injury."

Beischer, D. E.: "Effect of simulated flight stresses on the concentration of serum *cholesterol*, *phospholipid* and *lipoprotein*." *J. Aviat. Med.* **27**: 260-266 (1956) (24 refs.). J13,199/56

Marchbanks, V. H. Jr., Hale, H. B., Ellis, J. P. Jr.: "Stress responses of pilots flying 6-hour overwater missions in F-100 and F-104 aircraft." *Aerosp. Med.* **34**: 15-18 (1963). G2,360/63

In navy pilots flying six-hour overwater missions in F-100 and F-104 aircraft, corticoid levels were increased in the plasma but not in urine. Urinary EP and NEP values were considerably above normal, as was the excretion rate of *urea* and *uric acid*, while phosphate levels were not altered. The total reaction depended very much upon airplane characteristics and pilot experience.

Tabusse, L., Pannier, R., Gourves, P.: "Hypoglycémie et malaises chez l'aviateur" (Hypoglycemia and malaise in pilots). *Rev. Cps. Santé Armées* **6**: 623-637 (1965). G35,120/65

Hypoglycemia with malaise and hyper-

sensitivity to insulin may sometimes occur in pilots, but its relationship to stress remains in doubt.

Austin, F. H. Jr.: "A review of stress and fatigue monitoring of naval aviators during aircraft carrier combat operations: blood and urine biochemical studies." In: Bourne, P. G., *The Psychology and Physiology of Stress: With Reference to Special Studies of the Viet Nam War*, pp. 197-218. New York and London: Academic Press, 1969.

E8,568/69

Review on stress and fatigue-monitoring in naval aviators during combat operations on a U.S. Navy aircraft carrier in North Vietnam. Plasma phospholipid fractions behaved unlike those of normal individuals or those exposed to other stressors. "The *phosphatidylglycerol* responded to this type of stress more markedly and consistently than the other fractions. A discriminant functions formula has been developed which may facilitate identification of the stress type and degree of subject response up to and including psychophysiological exhaustion and collapse." Variations in typical stress hormone levels are also reported.

Lutwak, L., Whedon, G. D., Lachance, P. A., Reid, J. M., Lipscomb, H. S.: "Mineral, electrolyte and nitrogen balance studies of the Gemini-VII fourteen-day orbital space flight." *J. Clin. Endocrinol. Metab.* **29**: 1140-1156 (1969). H16,831/69

Metabolic studies on two astronauts during two weeks of orbital space flight (NASA Gemini VII) revealed considerable individual variations in metabolic responses. "In one man, significant increases in urinary *calcium* occurred during the second week of flight, and persisted during the recovery phase; calcium balance became less positive in flight in both subjects. Urinary *phosphate* excretion increased substantially in flight in both subjects despite reduction in phosphate intake. Urinary *nitrogen* and *sulfate* excretion decreased in flight but less than would be expected from the reduction in intake. Patterns of excretion of *magnesium*, *sodium*, *potassium* and *chloride* were different for each subject and could in part be correlated with changes in adrenocortical steroid production. The principal hormonal change was a striking decrease during flight in the urinary excretion of 17-hydroxycorticosteroids."

Pichler, H. J.: "Über ein interessantes Phänomen bei Schwerelosigkeit" (An interest-

ing phenomenon caused by weightlessness). *Arch. Klin. Exp. Ohren. Nasen-Kehlkopftheilk.* **202**: 543-548 (1972). H80,799/72

As soon as astronauts reach weightlessness after takeoff, they develop the illusion of standing on their heads because of increased blood supply to the brain. At the same time, *polyuria* sets in. [Stress is not specifically discussed (H.S.).]

Raichle, M. E., King, W. H.: "Functional hypoglycemia: a potential cause of unconsciousness in flight." *Aerosp. Med.* **43**: 76-78 (1972). J20,017/72

In a student pilot, functional *hypoglycemia* with unconsciousness developed during acceleration a few hours after a high carbohydrate meal.

→**Blood Count.** Pincus, G.: "Studies of the role of the adrenal cortex in the stress of human subjects." *Recent Prog. Horm. Res.* **1**: 123-145 (1947). 98,426/47

Excellent review on the biochemical changes characteristic of the G.A.S. in man, with special reference to 17-KS excretion and blood count as influenced by circadian variations, the stresses of daily life, operating a Hoagland-Werthessen pursuit meter, flying and exposure to heat. The response of schizophrenics is abnormal in many respects, and the question is raised whether adrenal malfunction may play a pathogenic role in mental disease (20 refs.).

Domanski, T. J., Nuttall, J. B.: "The physiological recognition of strain associated with flying." *J. Aviat. Med.* **24** Sect. 2, Supp.: 441-445 (1953). B96,198/53

Stress associated with flying causes definite eosinopenia in man.

Murphy, C. W., Gofton, J. P., Cleghorn, R. A.: "Effect of long-range flights on eosinophil level and corticoid excretion." *J. Aviat. Med.* **25**: 242-248 (1954). C5,680/54

Murphy, C. W., Cleghorn, R. A.: "Study of adrenocortical physiology in jet flying." *Can. J. Biochem.* **34**: 534-542 (1956).

C16,203/56

Flying a jet aircraft caused pronounced eosinopenia but only moderate increases in corticoid excretion and no alteration in salivary electrolyte concentration.

Domanski, T. J.: "Human stress response in contrasting aircraft operations." *Fed. Proc.* **15**: 51 (1956). C14,056/56

On training missions in B-47 and B-29 type aircraft, pre- and postflight eosinopenia was essentially similar in student and instructor pilots.

→**Cardiovascular System.** Morris, D. P.: "Blood pressure and pulse changes in normal individuals under emotional stress; their relationship to emotional instability." *Psychosom. Med.* **3**: 389-398 (1941).

B26,186/41

In student nurses undergoing examinations and student pilots performing different flying exercises for the first time, a rise in blood pressure was quite constant, while pulse rate was more variable and sometimes actually decreased during the stress. Pallor, tremor, flushing, excessive sweating, restlessness and apprehensive facial expression were also studied as possible indicators of stress, but the results proved more difficult to interpret.

Eliasch, H., Rosen, A., Scott, H. M.: "Systemic circulatory response to stress of simulated flight and to physical exercise before and after propranolol blockade." *Br. Heart J.* **29**: 671-683 (1967).

G50,658/67

Heart rate, blood pressure and cardiac output all increased in pilots during a Link trainer simulated flight, as well as after physical exercise on a bicycle ergometer. Comparisons with similar tests after propranolol administration "indicate that beta adrenergic receptor activity is extensively involved in the circulatory reaction to emotional stress. In contrast, this activity appears to be involved but less essential in the achievement of the circulatory adjustments during moderate physical exercise."

Scheinman, H. Z.: "Coronary atherosclerosis in military pilots: I. Relationship to flying and aviation accidents." *Aerosp. Med.* **39**: 1348-1351 (1968).

G85,445/68

Autopsies on 206 military pilots "demonstrate that the amount of flying time (when the age factor is considered) and type of aircraft are neither statistically related nor contributory to the severity of coronary atherosclerosis." It is concluded that drastic elimination of older aircrew will not significantly reduce aviation accidents.

Benetato, G., Adamache, A., Vrâncianu, R., Ionescu, V.: "Cercetari asupra asemnificării variatiilor telereogramei cardiotoracice în condiții de solicitare la aviatori" (The sig-

nificance of variations in the cardiothoracic telerheogram in airmen under conditions of stress). *Fiziol. Norm. Patol.* **18**: 385-394 (1972) (Roumanian). J20,500/72

Billings, C. E., Gerke, R. J., Chase, R. C., Eggspuehler, J. J.: "Stress and strain in student helicopter pilots." *Aerosp. Med.* **44**: 1031-1035 (1973). J11,332/73

Comparative studies on the tachycardia noted in student helicopter pilots under various conditions.

→ **Varia.** Jenson, R. L.: "Diabetes in flying personnel." *Aerosp. Med.* **32**: 1127-1134 (1961). D16,277/61

Stress associated with flying, especially combat missions, may lead to aggravation of preexistent diabetes.

Preston, F. S., Bateman, S. C., Short,

R. V., Wilkinson, R. T.: "Effects of flying and of time changes on menstrual cycle length and on performance in airline stewardesses." *Aerosp. Med.* **44**: 438-443 (1973) (21 refs.). J14,835/73

Ilin, E. A., Serova, L. V., Portugalov, V. V., Tigranian, R. A., Savina, E. A., Gaievskaya, M. S., Kondratiev, I. I., Noskin, A. D., Miliavski, V. I.: Iurov, B. N.: "Preliminary results of examinations of rats after a 22-day flight aboard the Cosmos-605 biostation." *Aviat. Space Environ. Med.* **46**: 319-321 (1975). J22,154/75

In rats under simulated weightless conditions in the Salyut and Skylab orbital stations, organ changes were not conspicuous, "except the weight of the spleen and the thymus which was lower in the experimental animals, and that of the adrenals and kidneys which was higher in the experimental rats."

Parachute Jumping

Parachute jumping produces definite indicators of stress, especially among beginners. The associated free anxiety enhances hippuric acid output following administration of sodium benzoate. There is also a rise in EP, NEP and corticoid excretion, as well as eosinopenia, and an increased GSR. Plasma 17-OHCS, EP, NEP, VMA, FFA and blood sugar elevations are less pronounced in experienced, competent parachute jumpers than in beginners.

Parachute Jumping

(See also our earlier stress monographs, p. xiii)

Korchin, S. J., Basowitz, H.: "Perceptual adequacy in a life stress." *J. Psychol.* **38**: 495-502 (1954). J13,189/54

Earlier observations have shown that stress with free anxiety elevates hippuric acid excretion following administration of a standard dose of sodium benzoate. During paratroop training, men with low hippuric acid excretion prior to the test are uniformly superior in performance, and proneness to stress responses is reflected in the prestress hippuric acid elimination rate.

Persky, H.: "Glutathione metabolism in men under psychological stress." *Psychosom. Med.* **16**: 489-495 (1954). J13,307/54

In man, blood-reduced glutathione is considerably lowered five to ten hours after parachute jumping but not after severe physical exercise. Despite this apparent lack of nonspecificity, "it is postulated that severe psychological stress operating over long periods may produce irreversible depression of the blood glutathione level and its associated metabolic dysfunctions."

Bloom, G., Euler, U. S. von, Frankenhaeuser, M.: "Catecholamine excretion and personality traits in paratroop trainees." *Acta Physiol. Scand.* **58**: 77-89 (1963). E20,130/63

In paratroop trainees, EP and NEP excretion rose during jumps as compared to rest periods. Increased pulse rate and eosinopenia were noted even during procedures preceding the jump.

Fenz, W. D.: "Conflict and stress as related to physiological activation and sensory, perceptual, and cognitive functioning." *Psychol. Monogr.* **78**: 1-33 (1964).

J7,687/64

Monograph on the relationship between real life stress (parachute jumping) created by an approach-avoidance conflict situation and physiologic activation (GSR) and performance. "Parachutists produced increasingly steep gradients of GSR to parachute-relevant and anxiety words with increasing proximity to a jump." They also became more reactive on the day of a jump, and showed a corresponding deficit in general performance which was measured by various sensory and cognitive parameters.

Landorenko, L. G., Kuz'mich, I. S., Mozzhukhin, A. S.: "Haematological characteristics of emotional stress induced by a parachute jump." *Fiziol. Zh. SSSR* **57**: 1140-1144 (1971) (Russian). J20,892/71

Fenz, W. D., Jones, G. B.: "Individual differences in physiologic arousal and performance in sport parachutists." *Psychosom. Med.* **34**: 1-8 (1972). G98,011/72

Arousal and performance studies in sport parachutists show that "while repeated exposure to a stressor is an important variable, there are also other variables not related to experience which are responsible for differ-

ences between subjects in their ability to deal effectively with stress."

Daniel, J., Mikulaj, L., Vrazda, L.: "Correlations between certain emotional and endocrine stress indicators in man." In: Németh, Š., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 255-258. Bratislava: Slovak Academy of Sciences, 1973. E10,473/73

Such chemical indicators of stress as plasma 17-OHCS, EP, NEP, VMA, FFA and blood sugar were less elevated in experienced parachute jumpers, whose performance was good, than in novices.

Fenz, W. D., Jones, G. B.: "Cardiac conditioning in a reaction time task and heart rate control during real life stress." *J. Psychosom. Res.* **18**: 199-203 (1974).

J15,137/74

In man, conditioned cardiac response to a task involves the gradual adaptive control of an involuntary reaction in anticipation of a stressor. This can be shown for a number of real-life stressors, particularly parachute jumping.

Deroanne, R., Cession-Fossion, A., Juchmes, J., Servais, J. C., Petit, J. M.: "Telemetric control of heart adaptation during automatic and free-fall parachute jumps." *Aviat. Space Environ. Med.* **46**: 128-131 (1975). J22,136/75

Air-Traffic Control

Despite their sedentary occupation and their agreeable working conditions (usually pleasant, air-conditioned rooms), air traffic controllers (ATCs) experience considerable stress, especially during busy work periods, presumably because they have to concentrate continuously and are personally responsible for the lives of many people. The longer they are in their profession the more they develop subjective feelings of disease. They also show objective indicators of stress, such as tachycardia, increased GSR, plasma phospholipids, phosphatidylglycerol and so on. Catecholamine excretion is roughly proportional to the number of aircraft operations supervised, and the morning rise in corticoid elimination does not tend to subside during the day or even when the ATCs are off-duty. Night shifts are particularly stressful.

Among ATCs, peptic ulcers, hypertension and probably also CHD are especially common. In one study, 32.5 percent of the ATCs suffered from peptic ulcers. In another group, the incidence was even higher.

Whereas there can be no doubt about predisposition to hypertension and peptic ulcers, the evidence for proneness to diabetes has yet to be confirmed.

Air-Traffic Control

(See also our earlier stress monographs, p. xiii)

Kozarovitskii, L. B.: "Dynamics of skin-galvanic reactions in control panel operators during their work of regulating airplane traffic." *Zh. Vyssh. Nerv. Deiat.* **14**: 387-396 (1964) (Russian). J23,845/64

Dougherty, J. D., Trites, D. K., Dille, J. R.: "Self-reported stress-related symptoms among air traffic control specialists (ATCS) and non-ATCS personnel." *Aerosp. Med.* **36**: 956-960 (1965). G34,323/65

On the basis of self-reported stress-related symptoms, "it is safe to conclude that as an Air Traffic Control Specialist progresses through his career the sicker he thinks himself to be in comparison with non-Air Traffic Control Specialists having similar years of experience, occupational status, and location." However, the authors admit that without confirmation by more objective medical indices, the true health status of ATCs remains in doubt.

Both subjective and objective methods are used to evaluate stress in ATCs.

Rohmert, W.: "An international symposium on objective assessment of work load in air traffic control tasks." *Ergonomics* **14**: 545-547 (1971). J19,715/71

Report on the first International Symposium on Objective Assessment of Work Load in Air Traffic Control Tasks arranged by the Stress in Air Traffic Control Research Association—SATCRA.

Melton, C. E. Jr., McKenzie, J. M., Polis, B. D., Funkhouser, G. E., Iampietro, P. F.: *Physiological Responses in Air Traffic Control Personnel: O'Hare Tower*. Federal Aviation Administration, Aviation Med. pamphlet, p. 11. Washington, D.C., 1971. G83,666/71

Among ATCs at O'Hare Tower, Chicago, pulse rates were higher on the busy evening shift than during the light morning shift. GSR tests indicated that adaptation to the morning shift was incomplete in five days. Blood fibrinogen was not elevated, but plasma phospholipids and phosphatidylglycerol did increase. Catecholamine excretion was related to the number of aircraft operations, and corticoid elimination rose late in the morning and failed to recover completely during the following off-duty rest period.

Smith, R. C., Melton, C. E., McKenzie, J. M.: *Affect Adjective Check List Assessment of Mood Variations in Air Traffic Controllers*, p. 8. Washington, D.C.: Department of Transportation, Federal Aviation Administration, 1971. G86,726/71

Description of Malmstrom's Composite Mood Adjective Check List (CMACL) which evaluates stress in ATCs by eliciting their own subjective assessment of eighty

adjectives (relating to aggression, anxiety, concentration, depression, distrust, dizziness, fatigue and so on). Night shifts prove to be especially fatiguing.

Hale, H. B., Williams, E. W., Smith, B. N., Melton, C. E. Jr.: "Excretion patterns of air traffic controllers." *Aerosp. Med.* **42**: 127-138 (1971). G81,175/71

Studies on ATCs at O'Hare Airport, Chicago, revealed increased catecholamine and corticoid excretion roughly proportionate to work stress during the day, with a return to normal after rest. "In many respects the stress of O'Hare tower work exceeded the stress induced by long or difficult flying operations, a 10-hour test in a flight-simulator (inexperienced subjects), or prolonged decompression."

Gee, B. M.: *Stress and Testing in Air Traffic Control*, p. 6. Report of the Canadian Ministry of Transport. Ottawa, 1972.

G98,569/72

Report prepared for the Canadian Ministry of Transport on ways of testing stress induced by the activities of ATCs.

Smith, R. C., Cobb, B. B., Collins, W. E.: "Attitudes and motivations of air traffic controllers in terminal areas." *Aerosp. Med.* **43**: 1-5 (1972). J8,605/72

ATCs at seventeen high-density airports answered questionnaires asking what they liked best or least about their jobs. The responses from the various facilities were very similar. In general, job challenge was the most-liked aspect, and management the least.

Grayson, R. R.: "Air controllers syndrome: peptic ulcer in air traffic controllers." *Illinois Med. J.* **142**: 111-115 (1972).

G99,015/72

In a large group of ATCs examined, 32.5 percent suffered from duodenal or gastric ulcers. "Peptic ulcer in this series is concluded to be a stress-related disease, the stress being occupational."

Wehrmacher, W. H.: "Seminar on stress." *Curr. Med. Dialogue* **39**: 1102-1105 (1972).

J7,675/72

Among 111 ATCs who sought medical advice, eighty-six showed x-ray evidence of intestinal lesions, and thirty-six of these had duodenal ulcers.

Grandjean, E.: "Ergonomie" (Ergonomics). *Rev. Méd. Suisse Rom.* **92**: 201-210 (1972). J19,073/72

As judged by blood EP and clinical obser-

vations, ATCs exhibit considerably stronger manifestations of stress than do telegraphists.

Smith, R. C., Melton, C. E. Jr.: *Susceptibility to Anxiety and Shift Difficulty as Determinants of State Anxiety in Air Traffic Controllers*. Federal Aviation Administration, Aviation Med. pamphlet, p. 3. Washington, D.C., 1973.

J17,246/73

The anxiety proneness scores as determined by the STAI "were predictive of the general A-state level of controllers, but were not predictive of the degree of anxiety experienced under the stress of difficult shifts."

"Happy landing." *Br. Med. J.* August 25, 1973, p. 421.

H75,451/73

Catecholamine excretion in ATCs was raised during periods of arduous work. It was also suggested that "certain so-called stress diseases, which could include coronary heart disease, though this condition was not amenable to analysis in the study, may be related to the controllers' work." These men are also predisposed to the development of peptic ulcers and hypertension.

Melton, C. E., McKenzie, J. M., Smith, R. C., Polis, B. D., Higgins, E. A., Hoffmann, S. M., Funkhouser, G. E., Saldivar, J. T.: *Physiological, Biochemical, and Psychological Responses in Air Traffic Control Personnel: Comparison of the 5-Day and 2-2-1 Shift Rotation Patterns*. Federal Aviation Administration, Aviation Med. pamphlet, p. 15. Washington, D.C., 1973. J15,362/73

At the Houston Intercontinental Tower, a two-two-one sequence (two evening shifts, two day shifts, one mid-shift) was compared with the straight five-day shift (five consecutive days on the same shift). "Physiological and psychological assessments showed no significant stress differences on the two schedules. On neither of the schedules did the con-

trollers' stress levels differ from the general population."

Melton, C. E., McKenzie, J. M., Polis, B. D., Hoffmann, M., Saldivar, J. T. Jr.: *Physiological Responses in Air Traffic Control Personnel: Houston Intercontinental Tower*. Federal Aviation Administration, Aviation Med. pamphlet, p. 19. Washington, D.C., 1973. J15,363/73

Studies on ATCs showed that "day work (heavy traffic load) at Houston was characterized by elevated levels of all stress indicators as compared with the mid-shift (light traffic); epinephrine excretion increased significantly during the last half of the mid-shift as compared with the first half. Urinary stress indicators (17-ketogenic steroids, epinephrine, norepinephrine) were all significantly elevated during day sleep as compared with night sleep, indicating less effective rest during day sleep."

Navy, Marine, Submarine

Very few studies have been published on the stressor effect of service in the Navy or Marine Corps, but the relationship between life in submarines and the G.A.S. has been explored extensively. Even training in tanks for submarine work produces such typical manifestations of stress as an increase in 17-KS and creatinine output; these

changes are still more evident on prolonged submarine trips. In submarine personnel on twenty-four hour sleep-wake schedules, the circadian cycles of urinary, testoid and corticoid elimination shifted their peaks, but available data are insufficient to establish a definite pattern.

Darrow, C. W., Henry, C. E.: "Psychophysiology of stress." In: Lindsley, D. B. et al., *Human Factors in Undersea Warfare*, pp. 417-439. Washington, D.C.: National Research Council, 1949. B47,919/49

Review on the relationships between psychologic factors and organic manifestations of the G.A.S. Special attention is given to undersea warfare (102 refs.).

Cook, E. B., Wherry, R. J.: "The urinary 17-ketosteroid output of naval submarine enlisted candidates during two stressful situations." *Human Biol.* **22**: 104-124 (1950). B48,615/50

In submarine enlisted candidates, stress-producing training in tanks evokes typical manifestations of the G.A.S., including an increase in 17-KS and creatinine output, although the two parameters are not strictly related.

Weybrew, B. B.: "Psychological problems of prolonged marine submergence." In: Burns, N. M., Chambers, R. M. et al., *Unusual Environments and Human Behavior*, pp. 87-125. Glencoe, Ill.: Free Press, 1963. E10,427/63

Brief review on psychologic disturbances during prolonged underwater voyages, particularly in relation to the concept of stress as applied to the closed ecology of submarines.

Crafts, R., Llerena, L. A., Guevara, A., Lobotsky, J., Lloyd, C. W.: "Plasma androgens and 17-hydroxycorticosteroids through-

out the day in submarine personnel." *Steroids* **12**: 151-163 (1968). G60,445/68

In submarine personnel on a twenty-four-hour sleep-wake schedule, the testosterone and androstenedione excretion rates were highest at 07:00 and lowest at night. The 17-OHCS peak shifted from 07:00 to 13:00 or 19:00 during an eighteen-hour day. The androgens also changed their peaks, although there was no correlation between these steroids and plasma LH. In males, therefore, androstenedione shows the same pattern and magnitude of circadian variations as 17-OHCS, "suggesting that it is primarily of adrenal origin."

Solodkov, A. S., Berdyshev, V. V.: "Development of states of physiologic stress in sailors during cruises in low latitudes." *Voen. Med. Zh.* **7** No. 7: 86-90 (1972) (Russian). J19,876/72

H85,587/73

Extensive study of the stressors encountered by tanker seamen (48 refs.).

Milton-Thompson, G. J.: "The problem of duodenal ulcer in the Royal Navy." *J. R. Nav. Med. Serv.* **60**: 45-48 (1974). J20,068/74

Davies, D. M.: "Physiological response to the submarine environment." *J. R. Nav. Med. Serv.* **60**: 28-33 (1974).

J20,065/74

Halliday, J. J., Rivers, J. F.: "Stress and myocardial infarction." *J. R. Nav. Med. Serv.* **60**: 52-54 (1974). J20,070/74

A statistical study of every naval rank from sub-lieutenant to vice-admiral indicated that "the stress of a naval environment does not appear to affect the incidence of myocardial infarction."

Diving

The stressor effect of diving, especially in relation to underwater demolition work, has been well established. Serum urate and cholesterol levels rise concomitantly with

the anticipated psychologic stress, whereas serum urate concentrations fall during the actual stress period.

In U.S. Navy underwater demolition teams, serum cortisol rose particularly during difficult training, and this may be associated with an elevation of serum uric acid and cholesterol.

In scuba divers practicing in cold water, heat loss added to the effects of anxiety, increased barometric pressure, and other stressors inherent in diving as such. In another group of scuba divers reaching depths of 30 meters or more, plasma cortisol levels and urinary EP excretion were high, although rectal temperature dropped only 0.33°C. Here, cold did not appear to add considerably to the stress of the situation.

The psychologic response, especially the motivation of the divers, seems to have a considerable effect upon the biochemical indicators of stress. In oxygen-helium dives, thiamine excretion was decreased, presumably because thiamine requirements are directly related to energy expenditure, and in such a situation "hyperbaric stress exacerbates exercise and cold stress, thereby creating a greater thiamine demand." In one of these divers, the changes persisted even after decompression.

Underwater task performance indicated that, in divers, sentence comprehension, aptitude at arithmetic, and manual dexterity did not appear to be considerably influenced at a depth of 30 meters, but memory was markedly diminished.

Diving

(See also our earlier stress monographs, p. xiii)

Sciarli, R.: "La plongée libre et ses dangers" (Free diving and its dangers). *Arch. Med. Gen. Trop.* **42**: 297-316 (1965).

G37,313/65

Review on diving as a stressor agent capable of eliciting the G.A.S., as indicated by its metabolic and hormonal consequences. Probably one important factor is hypoxia.

Baddeley, A. D.: "Diver performance and the interaction of stresses." *Underwater Assoc. Rep.* 1966-67, pp. 35-38.

J11.915/66-67

Rahe, R. H., Arthur, R. J.: "Stressful underwater demolition training. Serum urate and cholesterol variability." *J.A.M.A.* **202**: 1052-1054 (1967). F91,967/67

In men training for underwater demolition work, the serum urate concentration was elevated during anticipation of a demanding task, and "cholesterol levels rose concomitant with a period of particular psychological stress. Serum urate concentration demonstrated a significant fall during a period of quite intense psychological stress."

Skreslet, S., Aarefjord, F.: "Acclimatization to cold in man induced by frequent scuba diving in cold water." *J. Appl. Physiol.* **24**: 177-181 (1968). G55,183/68

Scuba divers practicing in cold water go through the: "1) unacclimatized stage: cold stress is met with by an elevated metabolic rate compensating heat loss. 2) intermediate stage: there is a fall in the rectal (core) temperature as heat loss is not fully compensated for by metabolism, believed to be caused by habituation of the CNS. 3) acclimatized stage: a constant rectal temperature is maintained, although minor metabolic heat is produced. Conservation of heat is attributed to lowered heat transfer with the blood to the body surface." [It is difficult to establish to what extent these reactions are truly non-specific and hence characteristic of stress as such, rather than of cold (H.S.).]

Rahe, R. H., Rubin, R. T., Arthur, R. J., Clark, B. R.: "Serum uric acid and cholesterol variability. A comprehensive view of Underwater Demolition Team Training." *J.A.M.A.* **206**: 2875-2880 (1968).

Rahe, R. H., Biersner, R. J., Ryman, D. H., Arthur, R. J.: "Psychosocial predictors of illness behavior and failure in stressful training." *J. Health Soc. Behav.* **13**: 393-397 (1972). J19,655/72

"A new unit scoring method was used to delineate recent life-change events from the Schedule of Recent Experience (SRE) questionnaire which correlated significantly with U.S. Navy Underwater Demolition Team (UDT) trainees' dispensary visits."

Davis, F. M., Charlier, R., Saumarez, R., Muller, V.: "Some physiological responses to the stress of aqualung diving." *Aerosp. Med.* **43**: 1083-1088 (1972). G95,712/72

Scuba (aqualung) diving in 12°C British coastal waters caused hormonal changes characteristic of stress. "Plasma cortisol levels were significantly raised before and after 30-meter dives when compared with 3-meter dives. Raised urinary levels of adrenalin, with high adrenalin to noradrenalin excretion ratios, were seen in several divers. The average decrease in rectal temperature was 0.33°C and mean skin temperatures remained approximately 16°C above ambient water temperature. Cold stress was considered unlikely to contribute to the hormonal changes seen. These changes are probably due to anxiety over deep open water diving in a 'stressful' diving situation" (22 refs.).

Russell, C. J., McNeill, A., Evonuk, E.: "Some cardiorespiratory and metabolic responses of scuba divers to increased pressure and cold." *Aerosp. Med.* **43**: 998-1001 (1972). H79,362/72

Rahe, R. H., Rubin, R. T., Gunderson, E. K. E.: "Measures of subjects' motivation and affect correlated with their serum uric acid, cholesterol, and cortisol." *Arch. Gen. Psychiatry* **26**: 357-359 (1972).

G90,674/72

Among trainees in a U.S. Navy underwater demolition team, "predominantly positive correlations were seen between the subjects' serum uric acid levels and their estimates of their own motivation. Their serum cholesterol concentrations demonstrated consistently negative correlations with their motivational and pleasant affect scores. Highest correlations were positive ones found between the subjects' serum cholesterol levels and their unpleasant affect scores. Serum cortisol correlations with the three psychological criteria demonstrated wide variability around a zero correlation baseline."

Davis, F. M., Osborne, J. P., Baddeley, A. D., Graham, I.M.F.: "Diver performance: nitrogen narcosis and anxiety." *Aerosp. Med.* **43**: 1079-1082 (1972). G99,706/72

Without being told that they were participating in a stress test, divers were asked to perform four tasks underwater at 3 m. and again at 30 m. These comprised a sentence comprehension test, a memory test, a simple arithmetic test and a manual dexterity test. All but the memory test showed a significant drop in efficiency at depth.

Rahe, R. H., McHugh, W., Kaplan, N., Rimon, R., Arthur, R. J.: "Serum lactic acid variability in subjects experiencing stressful training." *Dis. Nerv. Syst.* **33**: 403-408 (1972). H79,743/72

In a U.S. Navy underwater demolition team undergoing a psychologically and physically stressful training swim, serum lactic acid rose considerably. "In contrast to reports by other authors, no significant correlation was seen between subjects' serum lactic acid levels and a psychological questionnaire's indices of psychoneurotic symptomatology. A significant correlation was seen between a measure of physical fitness of the men and their serum lactic acid concentrations."

Frattali, V., Robertson, R.: "Nutritional evaluation of humans during an oxygen-helium dive to a simulated depth of 1000 feet." *Aerosp. Med.* **44**: 14-21 (1973).

H79,775/73

In man, oxygen-helium dives to a simu-

lated depth of 1000 ft. decreased thiamine excretion and erythrocyte transketolase activity. In one diver, these changes persisted to the end of the decompression phase. "Since thiamin requirement is directly related to energy expenditure, it is possible that hyperbaric stress exacerbates exercise and cold stress, thereby creating a greater thiamin demand."

Rubin, R. T., Rahe, R. H.: "U.S. Navy underwater demolition team training: bio-

chemical studies." In: Gunderson, E. K. E. and Rahe, R. H., *Life Stress and Illness*, pp. 208-226. Springfield, Ill.: Charles C Thomas, 1974.

Military Life, including Combat

(See also Concentration Camps, POWs; Catastrophe, Accidents; Aerospace, Navy, Marine, Submarine, Diving, Underwater Demolition Work, Driving and other special activities practiced by the Armed Forces)

Generalities. Many review articles deal with the various stressors encountered in military life at peace or war; these will serve as a general introduction to such problems.

→**Hormones.** Evidence of increased corticoid production in U.S. soldiers under combat conditions has been obtained in various theaters of war, including Korea, Japan and Vietnam. The reactions differ, depending upon the intensity and duration of the stress situation, and are generally associated with increased catecholamine excretion, but they are essentially the same in infantry men, bomber pilots and helicopter crews, and are accompanied by characteristic mental responses which will be discussed later.

Similar evidence of stress has also been noted under simulated combat conditions (taped sounds of real combat, shooting at targets, sleeplessness) which likewise result in increased catecholamine elimination.

Even in recruits during basic training, psychologic evidence of stress was correlated with 17-OHCS production. Measurements of both these parameters are considered to be more accurate tests of probable behavior during combat than are determinations of either alone.

Among Special Forces recruits, anticipation of imminent combat caused a drop in various testoids and their metabolites, conjointly with a rise in 17-OHCS.

→**Nonhormonal Metabolites.** Comparatively little is known about nonhormonal biochemical changes during military activities. However, allegedly, in naval aviators during combat, the phosphatidylglycerol response is more pronounced and consistent than during other types of stress.

→**Nervous System.** Of course, the most important neuropsychologic reactions to combat conditions are the so-called "war neuroses." Their development, like that of neuroses in peacetime, depends very largely upon both endogenous and exogenous con-

ditioning factors, such as hereditary predisposition, preparatory indoctrination to boost morale, interpersonal relations within the fighting group, and motivation.

The articles briefly summarized in the following pages contain valuable data not only on these factors, but also on the various classes of war neuroses, and their prophylaxis and treatment, as well as the associated metabolic (particularly endocrine) changes.

Some attention has also been given to the neuropsychiatric effects of military life during peacetime, especially among men not used to life under disciplined, strictly supervised conditions. Change in command appears to be a particularly stressful experience, both in peace and in war.

→**Peptic Ulcers.** Peptic ulcers of the stomach and duodenum are very common among combat casualties, as they are following burns, severe psychic insults, anxiety, and other severe stress situations in civilian life. They are even relatively frequent in peacetime soldiers who are undergoing particularly strict training and are subject to especially severe discipline.

→**Other Diseases.** Comparatively few investigators have reported data on general disease susceptibility in military life, especially during battle. It is known that dermatologic, respiratory and gastrointestinal diseases were particularly common on a U.S. Navy aircraft carrier in Vietnam, mostly among a small proportion of predisposed men who performed physically demanding or hazardous tasks during combat conditions. Illness was highest among younger men preoccupied with health.

The stressor effects of epidemics, wars, drastic technologic changes and economic or physiologic deprivation are very different in people of distinct cultural and ethnic backgrounds.

J16,132/73

→Hormones. Elmadjian, F.: "Adrenocortical function of combat infantrymen in Korea." In: *Ciba Found. Coll. Endocrinol.* **8**: 627-642 (1955). C3,666/55

Detailed studies on the physiologic, psychologic and psychiatric aspects of combat stress in U.S. infantrymen fighting in Korea and Japan. Extensive data on urinary steroid determinations and nitrogen metabolism during chronic and acute stress situations are compared.

Howard, J. M., Olney, J. M., Frawley, J. P., Peterson, R. E., Smith, L. H., Davis, J. H., Guerra, S., Dibrell, W. H.: "Studies of adrenal function in combat and wounded soldiers. A study in the Korean theatre." *Ann. Surg.* **141**: 314-320 (1955).

C20,630/55

In soldiers, there was no evidence of adrenal exhaustion as manifested by corticosteroid excretion, after prolonged exposure to combat situations in the Korean war.

Davis, S. W.: "Stress in combat." *Sci. Am.* **194**: 31-35 (1956). B28,532/56

Semipopular description of changes in urinary corticoids, 17-KS, electrolytes and blood count during combat in Korea. The responses differed according to the intensity and length of stress. After combat the men "were impassive, lethargic, uncommunicative, almost antisocial, where before being sent into combat they had been exuberant—telling stories, laughing and back-slapping. Yet our psychological tests failed to show any evidence of changes matching those in physiology." The reported alterations and their

chronologic development corresponded with projections based on the G.A.S. concept.

Artiss, K. L.: "Human behavior under stress—from combat to social psychiatry." *Milit. Med.* **128**: 1011-1015 (1963).

E31,186/63

Review of the literature on corticoid and EP excretion in soldiers under combat conditions.

"Stress in helicopter personnel." *J.A.M.A.* **201**: 320-321 (1967). F85,752/67

Studies on helicopter ambulance crews showed that the usual stress-induced increase in urinary corticoid excretion can be remarkably well controlled by certain psychologic adjustments minimizing the reality of the danger to be faced on combat missions and exaggerating the dangers already dealt with "in order to enhance... feelings of omnipotence and invincibility."

Rose, R. M., Poe, R. O., Mason, J. W.: "Psychological state and body size as determinants of 17-OHCS excretion." *Arch. Intern. Med.* **121**: 406-413 (1968). G57,520/68

In recruits undergoing basic combat training, both psychologic state and body size correlated significantly with 17-OHCS excretion. Combined use of both variables was most helpful in predicting performance (28 refs.).

Bourne, P. G., Rose, R. M., Mason, J. W.: "17-OHCS levels in combat. Special Forces 'A' team under threat of attack." *Arch. Gen. Psychiatry* **19**: 135-140 (1968).

G60,245/68

In a Special Forces team living in anticipation of attack on the Vietnam border, an officer and radio operator showed a rise in urinary 17-OHCS while the enlisted men showed a drop. Presumably, "assigned role in the group plays a major part in determining the effect of stress as measured by 17-OHCS excretion, and...when the opportunities for handling the stress are limited, group influences minimize the significance of individual differences."

Rose, R. M., Bourne, P. G., Poe, R. O., Mougey, E. H., Collins, D. R., Mason, J. W.: "Androgen responses to stress. II. Excretion of testosterone, epitestosterone, androsterone and etiocholanolone during basic combat training and under threat of attack." *Psychosom. Med.* **31**: 418-436 (1969).

G70,683/69

Among Special Forces recruits anticipating

imminent combat in Vietnam, testosterone, epitestosterone, androsterone and etiocholanolone excretion dropped, whereas 17-OHCS elimination rose. Although marked individual differences make the interpretation of data difficult, it appears that decreased 17-KS persisted but was associated with a parallel fall in 17-OHCS (39 refs.).

Poe, R. O., Rose, R. M., Mason, J. W.: "Multiple determinants of 17-hydroxycorticosteroid excretion in recruits during basic training." *Psychosom. Med.* **32**: 369-378 (1970). G77,861/70

In recruits during basic training, psychologic ratings and weight were correlated with, and together predicted, 17-OHCS levels more accurately than did either alone. In twelve of fourteen men who lost a parent, 17-OHCS values were extremely high. The results "suggested that an individual's 17-OHCS level is influenced by psychologic, biologic, historic and environmental variables" (27 refs.).

→**Metabolites.** Austin, F. H. Jr.: "A review of stress and fatigue monitoring of naval aviators during aircraft carrier combat operations: blood and urine biochemical studies." In: Bourne, P. G., *The Psychology and Physiology of Stress: With Reference to Special Studies of the Viet Nam War*, pp. 197-218. New York and London: Academic Press, 1969. E8,568/69

Review on stress and fatigue-monitoring in naval aviators during combat operations on a U.S. Navy aircraft carrier in North Vietnam. Plasma *phospholipid* fractions behaved unlike those of normal individuals or those exposed to other stressors. "The phosphatidylglycerol responded to this type of stress more markedly and consistently than the other fractions. A discriminant functions formula has been developed which may facilitate identification of the stress type and degree of subject response up to and including psychophysiological exhaustion and collapse." Variations in typical stress hormone levels are also reported.

→**Nervous System.** Simmel, E.: "War neuroses." In: Lorand, S., *Psychoanalysis Today*, pp. 227-248. New York: International Univ. Press, 1944. E85,797/44

A psychologic study of stress-induced war neuroses.

Moran, Lord: "Wear and tear." *Lancet* June 17, 1950, pp. 1099-1101. D78,877/50

Lecture on the relationship between the G.A.S. and battle fatigue.

Various authors: *Symposium on Stress*, p. 332. Washington, D.C.: Army Medical Service Graduate School, 1953. B87,548/53

A conference on stress sponsored by the Division of Medical Sciences, National Research Council, and the Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington, D.C. Numerous papers on the hormonal and nervous regulation of stress responses, with special reference to combat situations, interpersonal relationships, nutrition and adaptation to catastrophic events.

Sells, S. B.: *Military Small Group Performance Under Isolation and Stress. An Annotated Bibliography*. Technical Report No. 61-19, Project No. 8243-11, Vol. 1. Fort Worth: Dept. of Psychology, Texas Christian University, 1961. J13,019/61

Berkun, M. M., Bialek, H. M., Kern, R. P., Yagi, K.: "Experimental studies of psychological stress in man." *Psychol. Monogr.* **76**: 1-39 (1962). J2,509/62

In examining the well known phenomenon of degradation of behavior in combat, ex-

tensive psychologic studies have been carried out on the reactions of soldiers to simulated events such as aircraft emergencies, disruption of military exercise by misdirected artillery shells, forest fires and radioactive fallout. The associated stress effects were measured by the intensity of eosinopenia and corticoid excretion. Situations in which subjects thought themselves responsible for an explosion that was believed to have seriously injured other soldiers, produced the most extreme results according to all criteria used, including mental problem solving activities.

Grinker, R. R., Spiegel, J. P.: *Men Under Stress*, p. 484. New York, Toronto and London: McGraw-Hill, 1963. B18,363/63

Extensive monograph on the stressor effects of combat upon U.S. troops during World War II. There are sections dealing with genetic predisposing factors, the combat environment, morale, reactions after combat and applications to civilian psychiatry.

Levi, L.: "Physical and mental stress reactions during experimental conditions simulating combat." *Försvarsmedicin* **2**: 3-8 (1966). G35,833/66

Soldiers in the Swedish Army were exposed to a seventy-two-hour vigil which included being subjected to stressors (taped sounds of real combat, shooting at targets, sleeplessness) simulating battle conditions. Nervous (alertness, ECG) and physical (EP excretion, urine analysis) reactions were examined in relation to the resulting stress effect.

Levi, L. (ed.): *Emotional Stress. Physiological and Psychological Reactions. Medical, Industrial and Military Implications*, p. 280. Stockholm: Kungl. Boktryckeriet P. A. Norstedt and Söner, 1967. E7,006/67

International Symposium arranged by the Swedish Delegation for Applied Medical Defense Research. A large number of speakers presented papers on the relationship between the G.A.S. and various psychologic and biochemical (particularly hormonal) responses to emotional stressors of different kinds, especially those encountered in the armed forces.

Weybrew, B. B.: "Patterns of psychophysiological response to military stress." In: Appley, M. H. and Trumbull, R. T., *Psychological Stress. Issues in Research*, pp. 324-362. New York: Appleton-Century-Crofts, 1967. E10,339/67

Detailed review of the literature and per-

sonal observations on stress situations connected with military activities.

Bourne, P. G. (ed.): *The Psychology and Physiology of Stress*, p. 242. New York and London: Academic Press, 1969.

E8,563/69

Discussion of combat stress with special reference to observations made during the Vietnam war. Most of the contributors were army physicians who dealt with psychiatric problems of combat stress, heat stress in army pilots, stress and fatigue-monitoring of naval aviators. Interesting data are presented on corticoid and androgen excretion as influenced by combat situations.

Mayfield, D. G., Fowler, D. R.: "Combat plus twenty years. The effect of previous combat experience on psychiatric patients." *Milit. Med.* **134**: 1348-1354 (1969).

E55,698/69

A statistical study indicates that "service-connected disabilities were more common among combat veterans, suggesting that combat experience increases the probability of the presence of longstanding emotional illness." These may become manifest only years after a combat experience (11 refs.).

Crocq, L.: "Les névroses de guerre" (War neuroses). *Rév. Méd.* **10**: 57-62; 175-188 (1969).

G99,089/69

Review based principally on experiences in the French army between 1918 and 1962.

Grinker, R. R., Spiegel, J. P.: "Combat stress." In: Sahakian, W. S., *Psychopathology Today: Experimentation, Theory and Research*, pp. 197-202. Itasca, Ill.: F E Peacock, 1970.

E8,715/70

In a textbook on psychopathology, this chapter is devoted to the psychiatric manifestations of "combat stress" with special reference to narcoticsynthesis. Pentothal treatment can detect the relationship of a specific incident in combat to a conversion symptom.

Bey, D. R. Jr.: "Change of command in combat: a locus of stress." *Am. J. Psychiatry* **129**: 698-702 (1972).

G96,808/72

On the basis of purely psychologic indices, it is concluded that "in the military a change of command is particularly stressful for the members of the unit involved. A comparison of units, some of which showed few increases in the indices of organizational stress and some of which showed great increases, revealed a relationship between the administrative style of the departing com-

mander and the amount of stress experienced by the unit."

Schuckit, M. A., Gunderson, E.K.E.: "Job stress and psychiatric illness in the U.S. Navy." *J. Occup. Med.* **15**: 884-887 (1973).

J7,436/73

In the U.S. Navy, there appears to be some connection between job stress and psychiatric illness, but various other factors complicate interpretation of the data, which are much less clear-cut than the causal relationship between stress and physical illness.

→**Peptic Ulcers.** Sullivan, B. H., Hamilton, E. L.: "Peptic ulcer in military personnel. Incidence and management." *U.S. Armed Forces Med. J.* **6**: 1459-1468 (1955).

C8,406/55

Among U.S. Army personnel, the incidence of peptic ulcers has greatly increased in recent years as a consequence of intensive training and a tense international situation conducive to stress.

Stremple, J. F., Molot, M. D., McNamara, J. J., Mori, H., Glass, G. B. J.: "Posttraumatic gastric bleeding. Prospective gastric secretion composition." *Arch. Surg.* **105**: 177-185 (1972).

G93,305/72

In nine of fifty combat casualties, bleeding ulcers developed although steroid excretion remained within the normal range. Total gastric juice sialic acid output was independent of bleeding, but the total "leak" of plasma protein was greater in the gastric ulcer group. "Initial decreased acid output, accompanied by plasma protein 'leakage' into the gastric lumen, is consistent with back diffusion of H⁺ ions soon after trauma," as has been postulated for stress ulcers occurring in the G.A.S. (33 refs.).

Mori, H., Stremple, J., Glass, G.B.J.: "Stress ulcer following war wounds in Vietnam." *Clin. Res.* **21**: 723 (1973).

H69,455/73

Among soldiers wounded in Vietnam, gastric and duodenal ulcers were common.

Klettenhammer-Tischina, H. P.: "Die Ulkuskrankheit bei Soldaten des österreichischen Bundesheeres unter besonderer Berücksichtigung des Ulcus duodeni" (Peptic ulcers in soldiers of the Austrian army. Particular consideration is given to duodenal ulcers). *Wien. Med. Wochenschr.* **124**: 177-179 (1974).

H82,314/74

General discussion of factors involved in

the development of duodenal ulcers, with suggested therapeutic measures.

Crocq, L., Rabarihoela, O., Molinie, C., Essioux, H., Cristau, P., Laverdant, C.: "Etude psychosomatique des ulcères duodénaux chez le jeune adulte en milieu militaire" (Psychosomatic study of duodenal ulcer in young adults during military service). *Sem. Hôp. Paris* **51**: 465-469 (1975).

J23,316/75

→**Other Diseases.** Rubin, R. T., Gunderson, E. K. E., Doll, R. E.: "Life stress and illness patterns in the U.S. Navy. I. Environmental variables and illness onset in an attack carrier's crew." *Arch. Environ. Health* **19**: 740-747 (1969).

G70,058/69

Statistical studies on the occupations of enlisted men and the diseases they developed on board a U.S. Navy attack carrier during a six-month deployment in Vietnam. Dermatologic, respiratory and gastrointestinal disorders were most common. The majority of the illnesses occurred in a relatively small proportion of the population, with consistent elevations among men who performed physically demanding or hazardous tasks in hostile environments, that is, during combat periods.

Rubin, R. T., Gunderson, E. K. E., Arthur, R. J.: "Life stress and illness patterns in the U.S. Navy. IV. Environmental and demographic variables in relation to illness onset in a battleship's crew." *J. Psychosom. Res.* **15**: 277-288 (1971).

G99,748/71

On the battleship USS New Jersey during

a seven-month deployment in Vietnam, the illness rate was highest in combat periods particularly among men who performed hazardous jobs. The most common ailments were dermatologic and respiratory.

Rubin, R. T., Gunderson, E. K. E., Arthur, R. J.: "Life stress and illness patterns in the U.S. Navy. V. Prior life change and illness onset in a battleship's crew." *J. Psychosom. Res.* **15**: 89-94 (1971).

G82,945/71

Studies using the SRE questionnaire on the crew of the battleship USS New Jersey during combat in Vietnam revealed that "subjects with higher total life change scores based on the standard scoring system tended to have greater numbers of illnesses, but this scoring system was of little utility in predicting future illness for this sample. The life change scores based on the regression-derived scoring system did significantly discriminate future illness; the mean numbers of illnesses for the highest quartiles were about 50 per cent greater than those for the lowest quartiles."

Rubin, R. T., Gunderson, E. K. E., Arthur, R. J.: "Life stress and illness patterns in the U.S. Navy. VI. Environmental, demographic, and prior life change variables in relation to illness onset in naval aviators during a combat cruise." *Psychosom. Med.* **34**: 533-547 (1972).

G97,605/72

Among naval aviators flying combat missions from a U.S. aircraft carrier in Vietnam, illness rates were highest in the younger age groups and in those more preoccupied with health.

Automobile Driving

Because of the ever-increasing importance of automobile driving throughout the world, this stressor has received considerable attention. From a practical point of view, it is helpful to appraise its effects as if it were a single entity, but of course its stressor potentiality is due to a combination of factors: concentration (especially when driving at high speed in heavy traffic), anxiety, the physical discomfort of maintaining the same position, and boredom during prolonged trips. In addition, there is the concern of reaching one's destination on time, and—depending upon the construction of the vehicle—vibration, noise, and so on.

In general, it may be said that driving and other stressors elicit essentially the same physical and somatic manifestations, namely, eosinopenia, increased corticoid and catecholamine production, psychologic signs of nervous tension or exhaustion, elevated blood pressure, tachycardia and sweating.

These changes are most pronounced under dangerous conditions (for example, auto

races or very prolonged truck driving, especially if the cargo is flammable, explosive or particularly valuable).

β -Adrenergic blocking agents allegedly diminish the tachycardia, without affecting performance. In coronary candidates, S-T segment depression in the ECG or frequent premature ventricular contractions are readily induced by driving.

Increased plasma NEP levels may remain high even after an automobile race. The rise in urinary catecholamines is mainly a result of increased NEP excretion.

FFA levels are often elevated in race drivers, even before and after a race. This change, as well as the associated emotional stress, may likewise be diminished by β -blockade without interfering with performance.

A car simulator has been developed which can elicit reproducible degrees of stress under conditions suitable for the investigation of pharmacologic agents that may affect symptoms and performance.

In alcoholic drivers, subjective feelings of stress are significantly correlated with traffic accidents, but personality and demographic variables are not.

Automobile Driving

(See also our earlier stress monographs, p. xiii)

Fatigue and Hours of Service of Interstate Truck Drivers. Public Health Bull. No. 265. Washington, D.C.: GPO, 1941.

[Title unavailable] *Verkehrssicherheit* 11: 145 (1965).

J11,882/65

Practical observations on the stressor effect of automobile driving.

Hoffmann, H.: "Herzkrank am Steuer von Kraftfahrzeugen. Untersuchungen über das Kreislaufverhalten im Fahrversuch an gesunden und kranken Kraftfahrzeugführern" (Car driving and cardiac patients. Examination of blood circulation during driving in healthy and sick drivers). *Münch. Med. Wochenschr.* 37: 1790-1796 (1963).

E28,340/63

In cardiac patients, driving tends to cause ECG anomalies and unusually marked increases in blood pressure. "This shows that at

least for the driver with angina pectoris the operation of a vehicle is an irresponsible stress."

Schmid, E., Meythaler, C.: "Untersuchungen über die sympathico-adrenale Reaktion bei Autofahrern mit Hilfe der Vanillinmandelsäure-Bestimmung im Harn" (Examination of the sympathetic-adrenal reaction in drivers. Urinary vanillylmandelic acid excretion). *Klin. Wochenschr.* **42**: 139-140 (1964). F2,669/64

In ordinary city drivers and even in their passengers, VMA excretion increases considerably, implying raised catecholamine production during stress.

Mast, T. M., Jones, H. V., Heimstra, N. W.: "Effects of fatigue on performance in a driving device." *Highway Res. Rec.* No. 122: 93 (1966). J15,854/66

Burns, N. M., Baker, C. A., Simonson, E., Keiper, C.: "Electrocardiogram changes in prolonged automobile driving." *Percept. Mot. Skills* **23**: 210 (1966). J23,665/66

Simonson, E., Baker, C., Burns, N., Keiper, C., Schmitt, O. H., Stackhouse, S.: "Cardiovascular stress (electrocardiographic changes) produced by driving an automobile." *Am. Heart J.* **75**: 125-135 (1968). F92,986/68

Driving produces marked changes in cardiovascular functions, especially those measured by the ECG (39 refs.).

Selzer, M. L., Rogers, J. E., Kern, S.: "Fatal accidents: the role of psychopathology, social stress, and acute disturbance." *Am. J. Psychiatry* **124**: 1028-1036 (1968). E84,312/68

"Significantly more psychopathology and social stress were present in 96 drivers causing fatal accidents than in a matched control group." Twenty percent of the drivers had acutely disturbing experiences within six hours before causing a fatal accident (20 refs.).

Tauber, J. B.: "Diabetes in an occupational group." *J. Occup. Med.* **10**: 65-66 (1968). J15,861/68

The incidence of diabetes mellitus in truck drivers was about ten times the national average. [In view of the small number of cases examined, confirmation on a larger scale will be necessary (H.S.).]

Bellet, S., Roman, L., Kostis, J.: "The effect of automobile driving on catecholamine

and adrenocortical excretion." *Am. J. Cardiol.* **24**: 365-368 (1969). H16,504/69

In patients with CHD and in controls, "excretion of both catecholamines and 11-OHCS was found to be significantly increased during a two hour period of driving compared with a two hour control period. These results suggest that automobile driving represents a mental stress.... The electrocardiographic changes (ischemic type of S-T segment depression or frequent premature ventricular contractions, or both) which occur during driving in subjects with coronary artery disease are induced by this stress."

Taggart, P., Gibbons, D., Somerville, W.: "Some effects of motor-car driving on the normal and abnormal heart." *Br. Med. J.* October 18, 1969, pp. 130-134. H18,098/69

"Little or no change in the plasma catecholamine levels was noted in three coronary subjects immediately after a city drive compared with resting levels. All the racing drivers showed a considerable increase in noradrenaline, and in one instance adrenaline, immediately after racing."

McDonald, L., Baker, C., Bray, C., McDonald, A.: "Plasma-catecholamines after cardiac infarction." *Lancet* November 15, 1969, pp. 1021-1023. H18,916/69

In racing drivers, plasma NEP levels were greatly elevated immediately after the race. Following cardiac infarction, "patients with atrial dysrhythmias or early ventricular dysrhythmias had higher noradrenaline con-

centrations in their plasma. There was no such difference for patients with late ventricular dysrhythmias, and adrenaline levels were unremarkable. The raised noradrenaline levels are not thought to be related to stress because six other patients undergoing the stressful procedure of cardiac catheterisation had low levels."

Carruthers, M. O., Taggart, P.: "Study of plasma catecholamine and lipid responses to emotional stress." *Q. J. Med.* **40**: 578-579 (1971). J19,080/71

Public speaking raised the blood catecholamine and FFA values, as did the stress of racing driving.

Falkner, F.: "The stress of racing driving." *Lancet* March 27, 1971, p. 650.

J21,150/71

Taggart, P., Carruthers, M.: "Endogenous hyperlipidaemia induced by emotional stress of racing driving." *Lancet* February 20, 1971, pp. 363-366. H35,851/71

During racing driving, "the total catecholamine levels were grossly elevated, the increase being largely due to noradrenaline. The free-fatty-acid levels were also elevated one to three minutes before the start while the drivers were on the starting grid, and up to one hour after the race. The triglyceride levels were slightly elevated after the event, continued to increase, and reached a peak at one hour." Blood cholesterol showed no significant change.

Taggart, P., Gibbons, D.: "The motor-car and the normal and abnormal heart." *Triangle* **10**: 63-68 (1971). J16,979/71

ECG studies on ordinary and racing-car drivers "indicate strongly that emotionally induced angina, and borderline left ventricular failure, should be contraindications to holding a driving licence."

Ashton, H., Savage, R. D., Thompson, J. W., Watson, D. W.: "A method for measuring human behavioural and physiological responses at different stress levels in a driving simulator." *Br. J. Pharmacol.* **45**: 532-545 (1972). G92,253/72

Description of a car simulator with which it is possible to produce controlled and reproducible degrees of stress under conditions that are also suitable for the investigation of the effects of pharmacologic agents upon it. In this study, classic biochemical indicators of stress were not measured.

Ashton, H., Savage, R. D., Telford, R., Thompson, J. W., Watson, D. W.: "The effects of cigarette smoking on the response to stress in a driving simulator." *Br. J. Pharmacol.* **45**: 546-556 (1972). J14,838/72

Taggart, P., Carruthers, M.: "Suppression by oxprenolol of adrenergic response to stress." *Lancet* August 5, 1972, pp. 256-258.

H57,669/72

In racing drivers, oxprenolol given one hour before the race suppresses tachycardia, plasma FFA and plasma total catecholamine concentrations, as compared with values obtained on the same drivers on previous occasions. This β -blockade appears to diminish emotional stress without interfering with performance.

The stressor effect of automobile accidents may lead to an immediate disturbance of decision making conducive to flight from the scene of an accident. The legal implications in German courts are described.

Somerville, W.: "Emotions, catecholamines and coronary heart disease." *Adv. Cardiol.* **8**: 162-173 (1973).

J16,987/73

A statistical study shows that "certain experienced motor-car drivers with a history of coronary heart disease when driving in busy traffic develop angina, sinus tachycardia, ectopic beats and various arrhythmias. Healthy racing drivers, stimulated by the emotions of competition and danger, develop high-grade sinus tachycardia, raised plasma catechol-

amines and free fatty acids immediately before and after a race. Public speaking induces in normal persons similar changes in heart rate and rhythm and elevations in plasma catecholamines and free fatty acids. In both drivers and public speakers, triglycerides show a peak elevation 1-2 h after the event. Oxprenolol inhibits the increase in heart rate, plasma catecholamines, free fatty acids and triglycerides."

Industry, Labor, Business, Finance

(See also Social Factors, Neuropsychologic Factors, Sound, Vibration, Temperature and Various other sections dealing with stressors common in industry and business)

Some occupations (for example, executive work, the practice of law, police work, shift work, the telephone and telegraph system and others) have been arbitrarily separated from those generally implied by the title, and have been assigned special sections because a good deal of research has been devoted to their stressor effect. Also, many readers may wish to find pertinent data without having to search through the entire literature on careers related to business and industry.

This arbitrariness is especially evident with regard to the section on executive life, since at any but the lowest level, some executive responsibility is inherent in all business. Nevertheless, we decided to separate the relevant literature for the convenience of those who are particularly interested in this aspect of stress, irrespective of the type of executive work involved. Of course, the stressor effects in most occupations overlap to such an extent that an exhaustive appreciation of the topic would require consultation of all related sections.

Some excellent articles have been cited for an overview of the stressors encountered in modern business and technology. Particularly interesting observations have been made on accountants, whose serum cholesterol levels consistently rose during severe

occupational stress periods when income tax and other reports had to be prepared. This type of stress also predisposes to CHD.

Among invoicing clerks, subjective feelings of fatigue and urinary catecholamine excretion increased whenever remuneration was changed from fixed salaries to piece wages, presumably because of the extra motivation to accomplish as much as possible in the shortest period. The stress of harried, concentrated work also tends to cause fatigue, backache and pain in the arms and shoulders.

An extensive study on 270,000 male employees of the Bell Telephone and Telegraph Company led to the conclusion that the high management group did not run a greater risk of CHD than those at lower levels. It was concluded that high responsibility is not particularly stressful. However, the many differences in the daily tasks, social and economic backgrounds, eating habits and so on, of the two groups would also have to be taken into account before generalizations could be made.

In industrial occupations, job satisfaction was negatively related to death from CHD. Job pressure undoubtedly aggravates distress in lower level employees, as well as in management. Furthermore, a good deal of evidence has been compiled to show the "curative effect of work satisfaction" on mental stress, and there is much literature on the distress caused by overpromotion, underpromotion, or managerial indifference to the personal problems of employees.

Allegedly, severe distress in industrial work may even lead to impotence or decreased fertility.

C56,083/58

In a large group of accountants, each subject's highest serum cholesterol consistently occurred during severe occupational or other stress, and his lowest at times of minimal

stress. The results could not be ascribed to any changes of weight, exercise or diet. Marked acceleration of blood clotting time consistently occurred when occupational stress was maximal, in contrast to normal blood clotting during periods of respite.

Rosenman, R. H., Friedman, M.: "The possible relationship of occupational stress to clinical coronary heart disease." *Calif. Med.* 89: 169-174 (1958).

C61,455/58

Review of the literature and personal observations show that all the predisposing factors for CHD (increased plasma lipids, intimal damage, altered hemodynamics, accelerated blood clotting) are affected by various types of stressors. It is suggested that "the increasing occupational stress unique to industrialized society plays a dominant role in the high incidence of clinical coronary heart disease."

J15,729/60

"The policy of 'being nice' to employees is fine for the company that is coasting along,

but it breaks down when there is real pressure for growth, expansion, and efficiency."

Buell, P., Breslow, L.: "Mortality from coronary heart disease in California men who work long hours." *J. Chron. Dis.* **11**: 615-626 (1960). E84,336/60

Statistical studies on the registered mortality of men in California suggest that long working hours predispose different occupational groups to CHD. Farmers and farm laborers, however, seem to be relatively protected. In any event, it appears that stress "may be associated with thrombotic complications but not necessarily with progressive atherosclerosis of the coronary arteries." The correlation between long working hours and coronary accident is particularly obvious among men under forty-five years of age in occupations involving deadline pressures.

Selye, H.: "Stress of technology: can man adjust?" *Ind. Can.* **63**: 223-226 (1962). D26,080/62

General considerations on man's ability to adjust to the stress created by modern technology.

Gwózdz, B.: "The effect of thermal stress on the level of 17-hydroxycorticosteroids in the blood serum of man." *Endokrinol. Pol.* **13**: 275-286 (1962) (Polish). D31,024/62

Studies on miners exposed to dry heat (29 refs.).

Pell, S., D'Alonzo, C. A.: "Acute myocardial infarction in a large industrial population. Report of a 6-year study of 1,356 cases." *J.A.M.A.* **185**: 831-838 (1963). E26,954/63

The age-adjusted incidence of myocardial infarction among male employees was inversely proportional to their annual income. These results are difficult to interpret because "the demands of a top-management job may be no more stressful than situations commonly encountered by persons in lower job levels, at work and at home. Secondly, men chosen for advancement may be those whose personal qualities are characteristic of both executive talent and resistance to coronary disease. It is conceivable, for example, that in selecting persons to assume greater responsibilities, supervisors and managers, knowingly or unknowingly, may tend to choose the better adjusted individuals, who by virtue of their personality and psychic state are better able to cope with life's stresses in general."

Kahn, R. L., Wolfe, D. M., Quinn, R. P., Snoek, J. D.: *Organizational Stress: Studies in Role Conflict and Ambiguity*, p. 470. New York, London and Sydney: John Wiley & Sons, 1964. E10,438/64

A monograph on "organizational stress," particularly in diverse social and industrial groups. There are some highly interesting data on the roles of conflict and ambiguity as they affect various personalities, but the word stress is used essentially as a synonym for difficulties, and not in its now generally accepted medical meaning (about 125 refs.).

Selye, H.: "The stress of life: new focal point for understanding accidents." *Ind. Med. Surg.* **33**: 621-625 (1964).

G11,115/64

Concise summary of the stress concept in relation to industrial accidents.

Levi, L.: "The stress of everyday work as reflected in productiveness, subjective feelings and urinary output of adrenaline and noradrenaline under salaried and piece-work conditions." *J. Psychosom. Res.* **8**: 199-202 (1964). G24,076/64

In female invoicing clerks, productivity, subjective feelings of fatigue, and urinary catecholamine excretion were enhanced when remuneration was changed from fixed salaries to piece-wages. The percentage of miscalculations was not altered during the period of increased productivity, but half the group complained of feeling harried, and experiencing fatigue, backache and pain in their arms and shoulders.

Jonderko, G.: "Effect of work mechanization upon the improvement of working condition and the accident rate in coal mining." *Med. Pracy* **15**: 237-243 (1964) (Polish). J16,122/64

Russek, H. I.: "Stress, tobacco, and coronary disease in North American professional groups. Survey of 12,000 men in 14 occupational groups." *J.A.M.A.* **192**: 189-194 (1965). F36,826/65

Statistical studies on twelve thousand professional men in fourteen occupational categories in the U.S. On the basis of questionnaires evaluated by specialists in each field, CHD was "strikingly related to the relative stressfulness of occupational activity" among physicians, lawyers, security analysts, and traders. In combination with emotional stress, high-fat diets and smoking were also associated with a high incidence of CHD. Smoking was most frequent in stressful occupations,

but unexpectedly, CHD was more common among nonsmokers than among persons who once smoked but gave it up. Possibly, "the ability to stop smoking may imply a resilient personality response to stress and diminished vulnerability to atherogenic influences."

Risk is influenced more by education and background than by occupational experience, in the Bell System." *Science* **161**: 238-246 (1968). H1,311/68

A five-year statistical study on the relation between occupation, education and CHD among 270,000 male employees of the Bell Telephone and Telegraph Company showed that "men who attain the highest levels of management as a group do not have a higher risk of coronary heart disease than men who remain at lower levels. The findings provide no evidence that men who have high levels of responsibility, or who have been promoted rapidly, frequently, or recently, or men who are transferred to new departments or to new companies, have any added risk of coronary heart disease." The difference is not necessarily due to social and economic backgrounds but may result from eating habits, smoking and lifestyles.

In miners, prolonged exposure to work stress caused "a significant decrease of all 3 classes of Ig. In the group exposed for a shorter time only the IgG decreased significantly."

Executive Life

A good deal has been written about the stressor effect of executive responsibilities in middle and top management, relative to that in subordinate employees merely following orders. Undoubtedly, executive responsibilities, if taken very seriously, produce severe distress, with somatic, psychic and often pathogenic consequences. However, here, as in all considerations of stress manifestations, conditioning factors cannot be neglected because whatever a person's position in the hierarchy of command, the stressor effect of his decision-making depends not only upon what he does or even what the consequences will be, but also upon the way he takes it. This explains the many contradictory statements about whether being the boss or being bossed about is more distressful or eustressful. Some people are leaders, others followers. The main problem each person must face squarely is to determine what he actually prefers to do, and behave accordingly. I know from personal experience that some highly intelligent and capable employees in our Institute repeatedly refused promotions (which would have resulted in increased status and salary) because they had the insight to realize that the higher level of responsibility would have brought with it too much frustration and job dissatisfaction.

However, the executive is also responsible for his employees, and hence must consider his organizational pattern in light of the fact that many of his subordinates will not be able to make these decisions for themselves.

It is a truism that the conscientious executive must make good rules and enforce them rigidly, but the real art is to know when to make exceptions. This is particularly true of promotion policies. It is common practice to promote personnel from a job in which they performed competently to a higher position. However, this process tends to go on until they have reached a level at which they are incompetent. To prevent this, the best technique I have been able to develop is to ask an employee temporarily to substitute for one in a higher position (to avoid disappointment, without revealing the wish to promote him); I then offer the higher post only after he has already shown his competence for it.

Executive Life

(See also our earlier stress monographs, p. xiii)

"Job stress and the executive: 6,000 managers report their experience." *Management Rev.* 47: 13-21 (1958). J14,312/58

Purely empirical but largely sound recommendations based on statistics concerning job satisfaction and interpersonal relationships.

"Stress stems from within the man himself, not from the outer forces of his living or working environment. In other words, their jobs aren't killing them—they are killing themselves."

Felton, J. S.: "How to live with executive stress." *Management Rev.* 47: 29-31 (1958). J14,313/58

Highly popularized brief comment.

Lee, R. E., Schneider, R. F.: "Hypertension and arteriosclerosis in executive and non-executive personnel." *J.A.M.A.* **167**: 1447-1450 (1958). C81,673/58

To the authors' surprise, among more than one thousand subjects in business, hypertension and cardiovascular disease (arteriosclerosis, CHD, myocardial infarction) were disproportionately low in the executive group. The authors note that "stress is a relative matter and that the disruption of the harmonious balance between a man and his environment can result from either the demands of the environment or the failure of the man to measure up to them. Success in a career goes hand in hand with good health. The executive, as part of his training, learns to judge the amount of occupational stress he can stand and to appreciate the value of outside avenues of expression."

Useem, J., Useem, R.: "Social stresses and resources among middle management men." In: Jaco, E. G., *Patients, Physicians and Illness. Sourcebook in Behavioral Science and Medicine*, pp. 74-91. Glencoe, Ill.: Free Press, 1958. J9,292/58

Analysis of the stress characteristics of middle management men, mainly regarding psychosocial factors.

Mortensen, J. M., Stevenson, T. T., Whitney, L. H.: "Mortality due to coronary disease analyzed by broad occupational groups." *Arch. Ind. Hyg.* **19**: 1-4 (1959).

E57,220/59

A statistical study shows that "in the Bell Telephone System there is no material difference in coronary mortality between the top management group and the craftsmen and laborers group but there is a marked difference between top management and middle management which is not explainable from presently available data. The popular notion that high executive positions are associated with high coronary mortality is likely due to the greater publicity connected with such deaths rather than to statistical facts."

Singer, H. A.: "The management of stress." *Adv. Management.* **25**: 11-13 (1960). J14,314/60

Popular review on stress, especially as it affects managers, with recommendations on the avoidance of distress.

Selye, H.: "Stress: its implications in everyday life." *Merit News* **13**: 1-4 (1961). C95,847/61

Popular article on the role of stress in executive and business life.

Dunn, J. P., Cobb, S.: "Frequency of peptic ulcer among executives, craftsmen, and foremen." *J. Occup. Med.* **4**: 343-348 (1962). J4,086/62

Statistical studies on several Pittsburgh companies showed that foremen suffered from peptic ulcer more frequently than craftsmen or executives. The data do not support the widely held notion that ulcer disease is unusually high among executives. "Though both the prevalence and the incidence of peptic ulcer within the several groups correlated well with the level of serum pepsinogen it remains an enigma that the mean pepsinogen levels should be lowest for the foremen and highest for the executives."

Ayers, A. W., Burr, H. B., Tuttle, W. B.: "Personality concomitants of peptic ulcer among managerial, supervisory, and presupervisory personnel." *J. Occup. Med.* **5**: 252-258 (1963) (26 refs.). E57,199/63

Webber, R. A.: "The roots of organizational stress." *Personnel* **43** No. 5: 32-39 (1966). J13,883/66

Discussion (with case reports) of the stress induced by poor organization in industry, particularly among managers.

Popular review on stress among executives.

Kiev, A.: *A Strategy for Handling Executive Stress*, p. 178. Chicago: Nelson-Hall, 1974. E10,800/74

The author uses as a motto for this monograph these words from Emerson's essay on self-reliance: "It is easy in the world to live after the world's opinion; it is easy in solitude to live after our own; but the great man is he who in the midst of the crowd keeps with perfect sweetness the independence of solitude." The book is replete with useful practical advice which can be characterized by a few quotations: "Every communication holds a stress. Business is a battle.... Stress and the drives of life are inseparable." The bodily manifestations of stress and its biochemical mechanism are given little attention.

Medicine, Dentistry, Nursing

(See also Diseases of Adaptation—where problems of veterinarians will be discussed conjointly with the spontaneous diseases of animals)

Medicine. A statistical study on more than twenty-five hundred physicians suggested that the incidence of CHD is higher among general practitioners and anesthesiologists than among dermatologists and pathologists, allegedly because the former two groups have a higher stress level.

In many U.S. hospitals where medical interns have particularly strenuous work shifts, their performance as well as their health is endangered because of excess

stress. Radiotelemetric observations on physicians and medical students performing stressful tasks almost invariably revealed tachycardia, which roughly paralleled urinary catecholamine excretion. This was particularly evident in surgical personnel encountering operative difficulties.

Patients admitted to hospital emergency wards frequently suffered such intense psychosocial stresses that the routine presence of a psychiatrist was recommended.

A statistical study on British physicians revealed a special predisposition to drug addiction, suicide and mental disease.

Obviously, considerable attention should be given to stress factors both among physicians and among their patients. Careful additional studies along these lines would be of considerable value in making definite recommendations for preventive measures.

Dentistry. Here we shall deal mainly with stress in the dentist and his patient. The role of stress in the development of dental disease will be discussed under the morphologic characteristics of stress.

Several investigators have studied the objective manifestations of stress in dental practice and have found that such typical indicators as increased corticoid and catecholamine production, as well as the typical psychic signs of distress, are readily detectable in both patients and the dentist, especially during complex and painful interventions. In several cases, the use of tranquilizers has been found to be justified and effective in combatting most of these complications, at least to a considerable degree.

Nursing. Among nurses, as among physicians, stress is undoubtedly most severe during work in intensive care units. Of course, temporary stress situations also arise during any unexpected crisis or in dealing with particularly difficult patients, especially in psychiatric wards. It is important to give due consideration to this stress factor because—as one author put it—many nurses are too much in need of support to give any, and obviously, their performance declines under such conditions.

Medicine, Dentistry, Nursing

(See also our earlier stress monographs, p. xiii)

Medicine. Holzknecht, F.: "Die Überlastung des Klinikarztes" (The overloading of the hospital physician). *Med. Klin.* **54:** 1789–1790 (1959). J23,201/59

Charvat, J.: "Stress reaction during operation." *Pol. Tyg. Lek.* **15:** 1647–1650 (1960) (Polish). J24,147/60

Discussion of the stressor effect of performing surgical operations in terms of the G.A.S.

Russek, H. I.: "Emotional stress and coronary heart disease in American physicians." *Am. J. Med. Sci.* **240:** 711–721 (1960). C97,308/60

On the basis of a questionnaire to which 2,587 physicians replied, general practitioners and anesthesiologists had a distinctly higher CHD rate than dermatologists and pathologists. The former two groups were rated as "high stress," the latter as "low stress" occupations. It is concluded that "emotional stress of occupational origin is one of the more important etiologic factors in the genesis of coronary artery disease among persons subsisting on a relatively high-fat diet."

Master, A. M.: "The role of effort and occupation (including physicians) in coronary occlusion." *J.A.M.A.* **174:** 942–948 (1960). J7,796/60

A general review of epidemiologic data does not convince the author that the fre-

quency of CHD has reached epidemic proportions, or that it is elicited by the stress of modern life. He believes that the apparently increased incidence of CHD is due to a rise in the mean age of the population and to improved diagnostic techniques.

Martin, H. W.: "Structural sources of strain in a small psychiatric hospital." *Psychiatry* **25**: 347-353 (1962). J23,456/62

Russek, H. I.: "Emotional stress and coronary heart disease in American physicians, dentists and lawyers." *Am. J. Med. Sci.* **243**: 716-725 (1962). D34,808/62

Questionnaires sent to ten thousand physicians, dentists and attorneys, aged forty to sixty-nine, revealed a definite positive correlation between occupational stress and CHD. "General practitioners in each field showed coronary heart disease prevalence rates 2 to 3 times those of the specialists selected for survey. No consistent relationship was found for prevalence rates of reported hypertension and occupational stress." Correlations of the data with the diets of these subjects "lend support to clinical and experimental studies which suggest that emotional stress is an important accelerating factor in atherogenesis when the diet is relatively high in animal fat" (28 refs.).

Ira, G. H., Whalen, R. E., Bogdonoff, M. D.: "Heart rate changes in physicians during daily 'stressful' tasks." *J. Psychosom. Res.* **7**: 147-150 (1963). E37,679/63

Radio-telemetric observations on the ECG of physicians and medical students showed that, during stressful tasks, tachycardia occurred in virtually all subjects though it was usually of short duration. Urinary catecholamine excretion roughly paralleled the tachycardia.

Russek, H. I.: "Stress, tobacco, and coronary disease in North American professional groups. Survey of 12,000 men in 14 occupational groups." *J.A.M.A.* **192**: 189-194 (1965). F36,826/65

Statistical studies on twelve thousand professional men in fourteen occupational categories in the U.S. On the basis of questionnaires evaluated by specialists in each field, CHD was "strikingly related to the relative stressfulness of occupational activity" among physicians, lawyers, security analysts and traders. In combination with emotional stress, high-fat diets and smoking were also associated with a high incidence of CHD. Smoking was most frequent in stressful occu-

pations, but unexpectedly, CHD was more common among nonsmokers than among persons who once smoked but gave it up. Possibly, "the ability to stop smoking may imply a resilient personality response to stress and diminished vulnerability to atherogenic influences."

Law

Among lawyers, too, CHD has been claimed to be particularly frequent if their work is associated with considerable stress. On the other hand, based on a questionnaire answered by almost two thousand attorneys in the Cleveland area, CHD was correlated with law school quality but not with the stress-ranking of their legal specialties. These observations, as well as serum cholesterol determinations, did not supply sufficient evidence to show that the practice of law is especially likely to predispose to stress-induced disturbances.

Law

(See also our earlier stress monographs, p. xiii)

Russek, H. I.: "Emotional stress and coronary heart disease in American physicians, dentists and lawyers." *Am. J. Med. Sci.* **243**: 716-725 (1962). D34,808/62

Questionnaires sent to ten thousand physicians, dentists and attorneys, aged forty to sixty-nine, revealed a definite positive correlation between occupational stress and CHD. "General practitioners in each field showed coronary heart disease prevalence rates 2 to 3 times those of the specialists selected for survey. No consistent relationship was found for prevalence rates of reported hypertension and occupational stress." Correlations of the data with the diets of these subjects "lend support to clinical and experimental studies which suggest that

emotional stress is an important accelerating factor in atherogenesis when the diet is relatively high in animal fat" (28 refs.).

Russek, H. I.: "Stress, tobacco, and coronary disease in North American professional groups. Survey of 12,000 men in 14 occupational groups." *J.A.M.A.* **192**: 189-194 (1965). F36,826/65

Statistical studies on twelve thousand professional men in fourteen occupational categories in the U.S. On the basis of questionnaires evaluated by specialists in each field, CHD was "strikingly related to the relative stressfulness of occupational activity" among physicians, lawyers, security analysts and traders. In combination with emotional stress, high-fat diets and smoking were also associated with a high incidence of CHD. Smoking was most frequent in stressful occupations, but unexpectedly, CHD was more common among nonsmokers than among per-

sons who once smoked but gave it up. Possibly, "the ability to stop smoking may imply a resilient personality response to stress and diminished vulnerability to atherogenic influences."

Friedman, E. H., Hellerstein, H. K.: "Occupational stress, law school hierarchy, and coronary artery disease in Cleveland attorneys" (abstracted). *Circulation* 32: II-89 (1965). F59,156/65

As indicated by questionnaires answered by almost two thousand attorneys in Cleveland, "coronary prevalence correlated with

law school quality, but not with stress-ranking of legal specialties."

Friedman, E. H., Hellerstein, H. K., Jones, S. E., Eastwood, G. L.: "Behavior patterns and serum cholesterol in patent attorneys (P)." *Circulation* 32: II-89-II-90 (1965).

J2,902/65

On the basis of interviews, 107 male patent attorneys were divided into types A and B according to the personality classification criteria of Rosenman and Friedman. Differences in serum cholesterol were not significant between the two groups.

Police Work

Although policemen undoubtedly have to cope with many stressors, comparatively little attention has been paid to their problems from this point of view. Of course, working only night shifts, particularly variable day and night shifts or unusually long hours, as well as meeting extraordinary dangers in dealing with criminals, are undoubtedly sources of distress frequently encountered in typical police work. Yet a statistical study on a large number of Cincinnati policemen somewhat surprisingly revealed, in reply to questionnaires, that they themselves assessed as their most important stressors those circumstances which threatened their sense of professionalism. It must be kept in mind that even off the job the policeman must accept prejudice, suspicion, and hostility from a large segment of the population, all of which causes considerable job dissatisfaction. This, in turn, leads to a good deal of disappointment, especially when the policeman compares his work to the closely related activities of military personnel, who face similar dangers only in times of war, yet are generally held in high esteem.

Police Work

J7,424/73

Popularized summary of occupational stress as a work hazard, with special reference to policemen, ATCs and shift workers.

Kroes, W. H., Margolis, B. L., Hurrell, J. J. Jr.: "Job stress in policemen." *J. Police Sci. Admin.* 2: 145-155 (1974).

J10,489/74

This statistical study on one hundred Cincinnati policeman revealed through questionnaires that their most significant stressors were those circumstances which threatened their sense of professionalism. "In fact, these stressors were more frequently mentioned and more heavily emphasized than were directly life-threatening stressors." Even off

the job, the policeman must accept prejudice, fear, suspicion and hostility from a large segment of society. In addition, there are physical dangers inherent in the occupation. There is much interesting material on the stressors that cause greatest job dissatisfaction among policemen, but adequate statistical evaluation of their predisposition to stress diseases is still lacking.

Kirkham, G. L.: "From professor to patrolman: a fresh perspective on the police." *J. Police Sci. Admin.* **2**: 127-137 (1974).

J10,534/74

General considerations on the stressors encountered in police work.

Kroes, W. M., Hurrell, J. J. Jr., Margolis, B.: "Job stress in police administrators." *J. Police Sci. Admin.* **2**: 381-387 (1974).

J19,592/74

Studies on administrators of the Cincinnati Police Department suggested that "the most significant stressors seemed to be a result of the administrator's being in the position of the 'man in the middle' while complex demands were being made upon him from the community, his superiors, and subordinates."

Shift Work

The stressor effect of work on prolonged, and particularly on varying, night shifts, or merely that of unusually long hours, has generated much attention. Yet the circadian rhythm of plasma corticoids appears to remain unaltered in both night workers and blind persons, which would suggest that at least this change is not considerably affected by light.

On the other hand, working long hours predisposes various occupational groups to CHD, except farmers and farm laborers, who would appear to tolerate long working hours unusually well. The association between long working hours and CHD is especially striking in men under forty-five years of age who work under pressure trying to meet deadlines.

In one study, reference is made to the comparatively high incidence of peptic ulcers and gastritis among shift workers, but the causative role of stress has not been clearly established here; questionnaires merely suggested that night shifts are particularly fatiguing and conducive to psychologic manifestations of distress.

Night work causes least alteration in adrenocortical rhythm in people adapted to it and who work in a community in which this sort of life is universal and generally accepted so that it does not provoke social problems. Rotating shift work, on the other hand, appears to produce the greatest disturbances in corticoid and catecholamine secretion indicative of stress.

Measurements on machine operators in a Swedish paper mill showed that EP and NEP excretion was lowest on the night shift, although fatigue ratings were highest.

In any event, all investigators agree that shift work becomes less stressful in proportion to habituation and that being "excluded from society" is perhaps the most prominent complaint among night shift workers.

Conroy, R. T. W. L., Elliott, A. L., Mills, J. N.: "Circadian rhythms in plasma concentration of 11-hydroxycorticosteroids in men working on night shift and in permanent night workers." *Br. J. Ind. Med.* **27**: 170-174 (1970). H24,017/70

Comparative studies of plasma corticoid levels were made in newspaper printing shop employees who regularly worked at night, and in engineering factory workers on monthly rotation shifts. Among the newspaper workers, maximal concentrations were noted around 14:00 when they awoke, whereas the

pattern was much more irregular in the engineering shift employees. "It appears that the adrenal cortical rhythm can be adapted to night work in a community in which this is universal, accepted and lifelong, but that such adjustment is unusual in men on night shift work for limited periods, and whose associates are mainly following a usual nyctohemeral existence."

Colquhoun, W. P., Edwards, R. S.: "Circadian rhythms of body temperature in shift-workers at a coalface." *Br. J. Ind. Med.* **27**: 266-272 (1970). J12,866/70

Hale, H. B., Williams, E. W., Smith, B. N., Melton, C. E. Jr.: "Neuroendocrine and metabolic responses to intermittent night shift work." *Aerosp. Med.* **42**: 156-162 (1971). G81,174/71

In six men studied nightly during cycles of unaccustomed alternating shift work, "evidence was obtained of work-associated neuroendocrine and metabolic hyperactivity (nonspecific stress) which was most distinct during the first week of morning work. Relatively high values of urinary epinephrine and 17-OHCS were found during morning periods in the weeks in which there was no morning work, indicating that the rotating shift schedule itself, not just the night work, acted as a stressor. An adaptive change was evident, since there was a lessening of the physiologic disturbance with each return to morning duty, as judged by urinary epinephrine, norepinephrine, 17-OHCS, and urea."

Smith, R. C., Melton, C. E., McKenzie, J. M.: *Affect Adjective Check List Assessment of Mood Variations in Air Traffic Controllers*, p. 8. Washington, D.C.: Department of Transportation, Federal Aviation Administration, 1971. G86,726/71

Description of Malmstrom's Composite Mood Adjective Check List (CMACL) which evaluates stress in ATCs by their subjective assessment of eighty adjectives (relating to aggression, anxiety, concentration, depression, distrust, dizziness, fatigue and so on). Night shifts prove to be especially fatiguing.

Review on the influence of night or shift work upon the well-being and productivity of packers, in relation to natural circadian rhythm.

Sobczyk, W., Markiewicz, L.: "Catecholamine excretion in the urine during work with a high emotional load." *Acta Physiol. Pol.* **23**: 65-72 (1972) (Polish).

H55,094/72

At a thermal-electric power plant, in control room workers who worked in three shifts (06:00-14:00, 14:00-22:00, and 22:00-06:00) at tasks demanding constant attention, the highest EP and 17-OHCS elimination values were found in first-shift and the highest NEP excretion rates in third-shift employees. However, the authors claim that "the excretion of catecholamines and 17-OHCS is markedly below normal values. The results point to a low emotional load during the work performed; this is the result of a practice of long standing."

Vaisfel'd, I. L., Il'icheva, R. F.: "Diurnal rhythm of the content of biogenous amines (histamine, serotonin) in human blood under normal conditions and during altered work-sleep cycles." *Kosm. Biol. Med.* **6** No. 5: 56-62 (1972) (English translation of Russian original).

H79,765/72

The histamine-diaminoxidase system shows considerable circadian variations in healthy subjects. The blood 5-HT content tends to decrease at night. Changes in the work-sleep cycle cause fluctuations in these parameters "related not only to the stressor applied, but also to the initial state of the organism." These findings are especially important in space medicine.

Fröberg, J., Karlsson, C. G., Levi, L.: "Shift work: a study of catecholamine excretion, self-ratings and attitudes." In: Swenson, A., *Night and Shift Work*, Rep. No. 11, pp. 10-20. Studia Laboris et Salutis, 1972.

J4,858/72

Correlation between catecholamine excretion and shift work among operators of machinery in a Swedish paper mill. Fatigue ratings increased sharply within the afternoon and night shifts; EP and NEP elimination was lowest on the night shift.

Ehrenstein, W., Schaffler, K., Müller-Limmroth, W.: "Die Wirkung von Oxazepam auf den gestörten Tagschlaf nach Nachschichtarbeit" (The effect of oxazepam on day sleep disturbed due to night work). *Arzneim. Forsch.* **22**: 421-427 (1972).

J15,868/72

In nurses doing night shift work, oxazepam aided adjustment to sleeping during the day. "In oxazepam day sleep, the sleep of stage 3

and 4 and the REM sleep were increased to the values registered in night sleep. In oxazepam day sleep the share of waking periods remained clearly below the reference values of normal day and night sleep. Stages 1 and 2 of orthodox sleep were increased in oxazepam day sleep as compared to normal day sleep but did not reach the values of night sleep."

Kaatzsch, H.: "Endogene Cholesterinbildung bei Kraftfahrern, Akkord- und Schichtarbeitern" (Endogenous cholesterol synthesis in truck drivers, piece-workers and shift-workers). *Med. Klin.* **67**: 262-266 (1972).

J16,980/72

In truck drivers and shift-workers, increases in blood cholesterol roughly paralleled the elevation of blood catecholamines, and reflected the severity of the stress associated with their work.

Östberg, O.: "Interindividual differences in circadian fatigue patterns of shift workers." *Br. J. Ind. Med.* **30**: 341-351 (1973).

H79,224/73

Data from computer operators working on different shifts show individual differences in circadian fatigue patterns. "By means of a questionnaire on preferences and habits of activity and time of day, three subgroups of five subjects each were selected—'morning,' 'middle,' and 'evening' groups. Significant differences were found between the groups and between the shifts. Most interesting was the significant interaction of group x shift, on the basis of which it could be concluded that the 'morning' type of subjects had the most pronounced difficulty in adapting to the shift system practised."

Margolis, B. L.: "Stress is a work hazard, too." *Ind. Med. Surg.* **42**: 20-23 (1973).

J7,424/73

Popularized summary of occupational stress as a work hazard with special reference to policemen, ATCs and shift-workers.

Telephone and Telegraph Operators

Several statistical studies have been performed on stress in telephone and telegraph operators because they have to be constantly alert. It was found that, in women, mere operation of a telephone switchboard sufficed to produce eosinopenia. The high rate of absenteeism among them was likewise considered to be a result of their stressful occupation.

In Australia, neurosis was studied comparatively in several occupational groups.

A correlation with the typical stress diseases was not particularly evident, although bronchial and gastrointestinal disturbances and absenteeism were common. In any event, neurotic complaints and absenteeism were decreasingly frequent among telegraphists, clerks and mechanics. The most common complaints (rigid job supervision, noise, drug and drinking habits) were not so much due to the work itself as to the response of the workers to their tasks.

Telephone and Telegraph Operators

(See also our earlier stress monographs, p. xiii)

Tatai, K., Mori, Y., Ito, K.: "Response of the pituitary-adrenocortical system to mental strain in healthy women." *Jap. J. Physiol.* **1**: 316-319 (1951). B59,995/51

In women, the stressor effect of calculating or of operating a telephone switchboard sufficed to produce pronounced eosinopenia.

Hinkle, L. E. Jr., Plummer, N.: "Life stress and industrial absenteeism. The concentration of illness and absenteeism in one segment of a working population." *Ind. Med. Surg.* **21**: 363-375 (1952). B29,097/52

Among 1,297 telephone operators, it was found that a high rate of absenteeism was common in those "exposed throughout their period of employment to life situations and experiences which were to them stressful."

J22,116/70

Grandjean, E.: "Ergonomie" (Ergonomics). *Rev. Méd. Suisse Rom.* **92**: 201-210 (1972). J19,073/72

As indicated by blood EP and clinical observations, ATCs exhibit considerably

stronger manifestations of stress than do telegraphists.

Ferguson, D.: "A study of neurosis and occupation." *Br. J. Ind. Med.* **30**: 187-198 (1973). H69,794/73

In Sydney, Melbourne and Brisbane, neurosis was much more frequent among telegraphists than among those in other occupations. "An increase in indices of mental stress was noted but some disorders commonly attributed to stress were not unduly prevalent in neurotics." Yet absenteeism ascribed to bronchial and dyspeptic ailments or injury appeared to be especially persistent.

Ferguson, D.: "A study of occupational stress and health." *Ergonomics* **16**: 649-663 (1973). J8,265/73

Systematic studies, undertaken because of claims by telegraphists' unions in various cities of Australia, showed that the proportion of neurotic absentees was greater in telegraphists than in clerks, and greater in clerks than in mechanics. "The only occupational characteristics that could be identified strongly with neurosis were the negative attitudes to job supervision, and noise in the workplace, though the drug habits of smoking, drinking and analgesic-taking (all strongly associated with neurosis) were also work-related." The most common complaints were due not so much to the work itself but to the response of the workers to their tasks. No clear association was found between neuroses and such disorders as hypertension, CHD, asthma, nasal allergy and migraine. Remedial measures are suggested.

Various Other Occupations

Apart from a few comparative publications on the stressor effects of diverse occupations, the special studies cited here have been carried out on students, musicians, train dispatchers, heat and power station workers, rickshaw pullers, fishermen, workers in Israeli kibbutzim, personnel of research and teaching institutions, and others.

PHYSIOLOGIC STATES

(In this section we will discuss such physiologic conditions as age, sex, pregnancy, and lactation only inasmuch as they can influence susceptibility to stressors. The changes that occur in the sex organs during stress have been arbitrarily listed under Morphologic Changes, since it is virtually impossible to separate structural variations in the gonads and mammary glands from the associated functional alterations. Data on pertinent hormone determinations will also be found under Chemical Changes. The effect of stress upon aging has been considered under Theories—Adaptation Energy and the Triphasic Nature of the G.A.S.)

Age

. The response to stressors is considerably influenced by age, and numerous investigators have analyzed its course from fetal life to senility. In general, young animals are more adaptable to the stressor effect of various agents, a fact that has been ascribed to their greater supply of "adaptation energy." The latter is admittedly a rather vague, though an indispensable concept; the well-known loss of adaptability becomes increasingly evident as an organism ages, and is one of the outstanding characteristics of senility.

On the basis of various function tests, it had been suggested that people who survive to a very advanced age in good health can "preserve a relatively intact pituitary-adrenal mechanism involved in response to acute stress."

Forced exercise on a treadmill during the first few weeks of life initially inhibited the growth of rats, but later they grew better and became much more resistant to exhaustion than controls. "It is not known whether improved treadmill performance is indicative of a general increased resistance to stress or is a specific effect of the early treadmill experience."

Data concerning the role of stress in producing normal or premature aging will be discussed in the sections on Theories in relation to Triphasic Nature of the G.A.S. There we shall list the many similarities between the stage of exhaustion (produced by intense stress applied during a short period) and the exhaustion of vitality as a consequence of aging.

A careful review of the entire literature led us to the conclusion that actually very little has been learned to date, or is likely to be elucidated in the immediate future, concerning the basic mechanism of aging. However, considerable progress is under way with regard to the prolongation of life as more and more is learned about the prevention and cure of those specific diseases (peptic ulcers, cardiovascular lesions, metabolic and nervous changes) that result in the phenomena characteristic of old age.

Many investigators have studied the early morphologic and functional development of the hypothalamus-pituitary-adrenocortical axis, as well as its behavior later in life in animals and man, because of its manifest importance for stress resistance. Considerable work has also been done on the effects of perinatal stress upon the development of this system. This will be discussed here, whereas other consequences of early

exposure to stress will receive attention in separate subsections later (see Pre- and Perinatal Stress, including Malformations).

→**CRF.** Apparently, the adrenals of the neonatal rat can respond to various stressors by corticoid discharge, presumably because CRF release is possible during the fetal and early postnatal stages of maturation. Allegedly, however, at about seven days of age, the rat develops an ACTH deficiency due to the failure of CRF to reach the hypophysis. In the newborn guinea pig, deafferentation of the hypothalamus interferes more seriously with growth and gonadal function than with corticoid secretion, especially in males. Allegedly, the STH- and gonadotropin-releasing factors are more dependent upon neural input than are those factors responsible for ACTH secretion.

It was known long before the development of the stress concept that anencephalic human fetuses tend to have atrophic suprarenal glands. This shows the importance of corticotropic stimulation, even for the prenatal development of the cortex. Furthermore, destruction of the hypothalamus during late fetal life interferes with the development of the hypophyseal-adrenal system. Yet, even after removal of the brain, the adrenal cortices of encephalectomized rat fetuses can be maintained at or near normal by the administration of CRF-containing extracts. The latter must act through the pituitary, since they have no effect upon the adrenal after decapitation, which removes the pituitary.

The circadian variations in the hypothalamic CRF of rats become manifest only when they are about three weeks of age. However, responses to stress occur much earlier. Even the fetal hypothalamus shows an immediate increment in CRF activity after stress, although the corresponding plasma cortisone rise may be delayed because of immaturity of the portal vessels. Allegedly, capillaries penetrate into the ME of the rat only on the fifth day after birth, but a capillary plexus between the ME and the pars tuberalis of the adenohypophysis is demonstrable on the eighteenth to twentieth day of fetal life in the rat, and apparently suffices to take up CRF, although this process is subsequently facilitated through invasion of the capillaries into the ME substance proper. In any event, when viewed under the EM, the ME of the newborn rat is very similar to that of an adult and contains a well-developed Golgi region and RES as well as some dense-core vesicles. Finally, ACTH-producing cells have been demonstrated by an immunohistochemical technique on the sixteenth day of fetal life in the rat. Thus, all morphologic and functional data are in agreement with the assumption that the elements for the neurohumoral control of ACTH discharge are efficacious even before birth.

Additional pertinent data which shed some light upon the maturation of CRF production will be found in the next sections which deal with the hypothalamus-pituitary-adrenal system and with pre- and perinatal stress.

→**Hypothalamus-Pituitary-Adrenal System.** Probably the first observation on the activity of this system was made in 1888 when Stilling found that, after removal of one adrenal, the contralateral gland undergoes compensatory hypertrophy in young but not in old rabbits. The next observation in this domain was made more than half a century later when we found that in immature, unlike in adult rats, large doses of estradiol cause considerable adrenocortical and pituitary hypertrophy.

There can be no doubt today that age influences the responsiveness of the cortico-

tropic mechanism, although the results obtained are variable and probably largely dependent upon the species and experimental conditions used.

The fetal rat's pituitary reacts to stressors, even after hypophysectomy of the mother. Furthermore, fetuses delivered by Cesarean section likewise respond to stressors; hence, it is not maternal ACTH that causes adrenocortical stimulation in the embryo. Allegedly, in neonatal rats, the adrenal ascorbic acid-depleting property of EP or cold is negligible, although ACTH is effective in this respect even during the first week. Yet, newborn infants appeared to excrete glucocorticoids in response to severe trauma soon after birth, and some investigators did observe adrenal ascorbic acid depletion following laparotomy in rats less than one week old.

Others claimed that electroshock (unlike vasopressin) fails to cause ascorbic acid depletion or increased corticosterone formation in the adrenal cortex during the first eight days of life in rats. They ascribed this "stress-non-responsive period" to immaturity of hypothalamic regulating centers; yet, in the same laboratory, compensatory adrenal hypertrophy was observed in newborn rats subjected to unilateral adrenalectomy. One reason why the findings of different authors appear to be so contradictory may be neglect of the considerable perinatal variations in adrenal weight. These occur during the first days of life, even without exposure to any experimental stimulus, and presumably reflect adaptation to extrauterine conditions. In any event, the results obtained differ so widely that no definitive generalizations are possible, and the individual data must be consulted in the original publications abstracted at the end of this section.

In some experiments, the pituitaries of newborn animals appeared to be irresponsible to stimulation by stressors; yet, there can be no doubt that, under appropriate conditions, stress is associated with increased adrenocortical activity not only immediately after birth, but even in fetal rats after the twentieth day of gestation.

→**STH.** In newborn infants, heel-pricks decreased plasma STH concentrations, contrary to the response of adults. In certain strains of dwarf mice predisposed to premature aging, indirect evidence suggested lower STH production before death, but this might have been due to stress.

→**Catecholamines.** In premature babies, urinary NEP excretion, unlike EP excretion, was subnormal after exposure to cold, possibly because in the newborn, cold rapidly exhausts NEP stores and thereby causes inability to stimulate and utilize chemical thermogenesis.

→**Metabolites.** The metabolic response of various animal species to stressors likewise depends upon their age. For example, in some premature, unlike in mature newborn mammals, cooling is generally not accompanied by significant glycogenolysis because of insufficient EP secretion. Furthermore, in malnourished children, cooling decreased rectal temperature more readily than in well-nourished controls. Plasma FFA in the human fetus is controlled by the same mechanism as in adults, but unlike the pregnant woman, the fetus is unable to respond to high plasma glucose concentration with a fall in plasma FFA. This difference may be due to a limited fetal insulin supply or to the inadequacy of the lipid-synthesizing enzyme systems.

→**Organ Lesions.** Almost every functional or structural change resulting from stress is age-dependent to some extent, but it would be futile to describe all of them in detail here. A few interesting examples will suffice. Young rats and babies are especially sensitive to the induction of peptic ulcers by stress. In menopausal women, flushes can be elicited by emotional stress.

→**Nervous System.** The psychologic reactions to virtually any stressor are naturally quite different in man and animals of different age groups, and relocation to relatives' or old folks' homes is one of the most important stressors for the elderly. Noise has less pronounced effects upon the sleep pattern of twenty-five-year-olds than upon that of aged people.

It has even been claimed that rats whose grandmothers were exposed to avoidance conditioning before mating, or to conditioned stress during pregnancy, were more active in a common open test field than were normal controls. Hence, it was concluded that "stress before or during pregnancy, like infantile handling, can influence the behavior of future generations beyond the immediate offspring of the manipulated females." However, this extraordinary result requires confirmation.

Several review articles deal with the stressors most commonly affecting children or aged people and with the delayed mental reactions caused in children by maternal stress during gestation, but these can be consulted in the abstract section.

Pre- and Perinatal Stress. So much research has been done on the effects of stress during embryonic and early postnatal life that we shall discuss this work conjointly here, irrespective of the stressors used or the organs affected.

For example, gentling and caressing rats during the first three weeks of life make them more resistant to restraint in adulthood, as indicated by various objective manifestations of stress. However, in such experiments, temperature variations must also be kept in mind, since it has been claimed that, at room temperature, handling of two-day-old rats increases their plasma corticosterone levels but if they are placed in handling cans maintained at 35.5°C, a similar reaction will not occur.

Among the most common results of prenatal stress are decreases in fertility, interruption of pregnancy and the development of malformations in the offspring.

A statistical study on a small group of mongoloid children suggested that emotional stress during pregnancy predisposes babies to this disease, but the evidence is not entirely convincing.

Age

(See also our earlier stress monographs, p. xiii)

Generalities. Selye, H.: "Studies on adaptation." *Endocrinology* 21: 169-188 (1937).

38,798/37

Experiments on rats showed that age and sex can noticeably influence resistance to stressors. "Old animals react more readily than young ones, possibly because much of their adaptation energy has already been used to meet the incidental demands of life.

This probably explains also why resistance against almost any alarming stimulus is more difficult to obtain in fully adult rats, a fact which led to the use of animals 2 to 3 months of age in preference to older ones for the purposes of the present experimental series. Females show a more marked involution of the lymphatic organs after exposure to alarming stimuli than males. This may find its explanation in the fact that the adrenals are larger in the female rat than they are in the male."

F58,465/65

Rats forced to run in a treadmill during the first few weeks of life initially lost weight but then grew better than the controls and

became much more resistant to exhaustion. "It appears that the treadmill acted as a stressor and that this 'acute stress' during infancy was responsible for the increased growth of muscle and other tissue. It is not known whether the improved treadmill performance is indicative of a general increased resistance to stress or is a specific effect of the early treadmill experience."

Gray, R. M., Baker, J. M., Kesler, J. P., Newman, W. R. E.: "Stress and health in later maturity." *J. Gerontol.* **20**: 65-68 (1965). F31,165/65

Statistical studies showed that among elderly people, those "who had experienced the most stress during the past ten years also had the poorest health scores. In addition, the data revealed that the severely disabled persons had significantly higher stress scores than did non-disabled older persons, which indicated that they had experienced more stress than the non-disabled."

Selye, H.: "The future for aging research." In: Shock, N. W., *Perspectives in Experimental Gerontology*, pp. 375-385. Springfield, Ill.: Charles C Thomas, 1966. G19,438/66

Final chapter of a jubilee volume in honor of Professor Fritz Verzár, based on a congress held in Vienna with the participation of numerous outstanding gerontologists. One of the principal conclusions is that aging may not have a single cause but represents the sum of the many morphologic and chemical scars accumulated during a lifetime of facing the most varied stressors. The speaker concluded by stating that "what I have said is not intended to dissuade creative minds from continuing their search for an all-embracing theory which might lead to the prophylaxis or even the cure of the aging process itself. My purpose was only to point out that, at present, we have no objective basis for suspecting that such endeavors could be fruitful, while we do have many reliable techniques (and good reasons to assume that even better ones could be developed) for the study of individual morbid lesions which decrease life expectancy."

Review of earlier literature showing that the adrenal glands of the neonatal rat respond to various stressors in a normal manner, whereas at about seven days of age a period of comparative nonresponsiveness sets in. The present experiments reveal similar age-dependent variations in the adrenal reaction to ACTH or to partial adrenalectomy. "The fetal and early postnatal maintenance of the pituitary levels of ACTH could be the result of a diffusion of CRF to the pituitary which becomes more difficult and fails with the growth and development of the rat. Thus the 7-day-old rat is showing signs of ACTH deficiency due to a failure of CRF to get to the pituitary gland." [The postulates concerning the role of CRF are purely hypothetical (H.S.).]

Joseph, S. A., Knigge, K. M., Voloschin, L.: "Effects of isolation of the hypothalamo-pituitary unit in newborn guinea pigs." *Neuroendocrinology* 4: 42-50 (1969).

H8,974/69

In newborn guinea pigs, deafferentation of the hypothalamus with a modified Halász-knife showed that within about three months "growth and gonadal function were most seriously impaired; development of thyroid and adrenal function was unaffected in male animals and only moderately affected in females. The results indicate that those RF-producing neurons associated with growth hormone and the gonadotrophins may require afferent neural connections for their normal maturation, while RF-producing neurons associated with thyrotrophin and corticotrophin may develop normally in the isolated hypothalamo-pituitary unit."

Jost, A., Dupouy, J. P., Geloso-Meyer, A.: "Hypothalamo-hypophyseal relationships in the fetus." In: Martini, L., Motta, M. et al., *The Hypothalamus*, pp. 605-615. New York and London: Academic Press, 1970.

J4,841/70

Experiments on various species as well as observations on anencephalic human fetuses indicate that mammalian ACTH activity is more strictly dependent upon the hypothalamus than is TTH function during prenatal life.

Fujita, T., Eguchi, Y., Morikawa, Y., Hashimoto, Y.: "Hypothalamic-hypophyseal adrenal and thyroid systems: observations in fetal rats subjected to hypothalamic destruction, brain compression and hypervitaminosis A." *Anat. Rec.* 166: 659-672 (1970).

G74,197/70

Observations suggest that "in the late period of fetal life in rats, the hypophysial-adrenal system is regulated largely by the hypothalamus," but that the hypophyseal-thyroid system is not fully under its control.

Hiroshige, T., Sato, T.: "Postnatal development of circadian rhythm of corticotropin-releasing activity in the rat hypothalamus." *Endocrinol. Jap.* 17: 1-6 (1970).

H27,251/70

In rats, the circadian rhythm of plasma corticosterone (with a peak in the evening and a nadir in the morning) as well as the concurrent circadian variations in hypothalamic CRF content, become detectable only when they are about three weeks of age.

Hiroshige, T., Sato, T.: "Circadian rhythm and stress-induced changes in hypothalamic content of corticotropin-releasing activity during postnatal development in the rat." *Endocrinology* 86: 1184-1186 (1970).

H25,238/70

In rats, development of a circadian rhythm in CRF activity becomes evident between the 14th and 21st day of postnatal life, whereas responsiveness to stressors is manifest by the 7th day. "The hypothalamic CRF may at least be one of the rate-limiting phases in the mechanism of stress nonresponsiveness during the first few days of postnatal life in the rat."

Hiroshige, T., Sato, T.: "Changes in hypothalamic content of corticotropin-releasing activity following stress during neonatal maturation in the rat." *Neuroendocrinology* 7: 257-270 (1971).

H42,531/71

Even fetal hypothalamic tissue exhibited an immediate increment of CRF after stress, but the plasma corticosterone rise was delayed, perhaps because of immaturity of the portal vessels. "Since the pituitary glands of the 2-day-old neonates contained ACTH, to which their own adrenals were quite responsive, it is most likely that inability of CRF release from the hypothalamus may be a cause of non-responsiveness to stress during this specific period. Furthermore, since a fetal response to stress as well as a day-1 neonatal responsiveness was clearly observed, it is probable that the day-2 neonatal non-responsiveness is a result of the previous activity associated with delivery and not a developmental rate limitation as suggested by others."

Hiroshige, T., Sato, T., Abe, K.: "Dynamic changes in the hypothalamic content

of corticotropin-releasing factor following noxious stimuli: delayed response in early neonates in comparison with biphasic response in adult rats." *Endocrinology* **89**: 1287-1294 (1971). H48,432/71

Hiroshige, T., Abe, K.: "Dynamics of activity of hypothalamic corticotropin releasing factor in the rat." *J. Physiol. Soc. Jap.* **34**: 529-530 (1972). H79,788/72

In rats, the circadian rhythm in hypothalamic CRF content (with a peak in the afternoon and a nadir in the morning) develops after two to three weeks of postnatal life, whereas responses to stress occur as early as the seventh day. The circadian rhythm persists in the absence of circulating corticosterone and hence appears to be dependent only upon nervous regulation, not upon negative feedback.

Milković, K., Milković, S.: "Studies of the pituitary-adrenocortical system in the fetal rat." *Endocrinology* **71**: 799-802 (1962).

D40,017/62

"Adrenal ascorbic acid depletion caused by stressful stimuli was the same in the fetuses of hypophysectomized rats as in those of normal rats." However, hypophysectomy of the fetus itself (for example, by decapitation) prevents a stress-induced adrenal ascorbic acid discharge. "These data show that at term the adrenals of fetuses are stimulated by the fetal pituitary."

Schapiro, S.: "Neonatal cortisol administration: effect on growth, the adrenal gland and pituitary-adrenal response to stress." *Proc. Soc. Exp. Biol. Med.* **120**: 771-774 (1965). F59,453/65

Eguchi, Y., Wells, L. J.: "Response of the hypothalamic-hypophyseal-adrenal axis to stress: observations in fetal and Caesarean newborn rats." *Proc. Soc. Exp. Biol. Med.* **120**: 675-678 (1965). F59,425/65

EP caused depletion of adrenal ascorbic acid in normal but not in decapitated fetal rats or in premature newborns obtained by Caesarean section. It is presumed that "in the rat the hypothalamic-hypophyseal-adrenal axis begins to function before birth and that after delivery this axis temporarily becomes refractory to stimulation by injected epinephrine."

Review and personal observations on the responsiveness of the fetal and neonatal adrenal to stress. The fetal adrenal cortex reacts to stressors with a slight but significant ascorbic acid depletion which is associated with a rise in plasma corticosterone in the rat. Such a result is also seen in fetuses delivered by Cesarean section; hence it is not dependent upon maternal or placental ACTH. Only decapitation of the fetus makes it unresponsive to stress. It is assumed that the stress of delivery and adaptation to extrauterine life causes an initial hyperfunction of the pituitary-adrenocortical system at birth, which manifests itself by low adrenal ascorbic acid and high plasma corticosterone in the newborn. It is further assumed that this hyperfunction limits the adrenocortical reserve, which is only about one-fifth that of the adult, and induces a relative nonresponsiveness to stressors during the first days of life (several hundred refs.).

Zarrow, M. X., Philpott, J. E., Denenberg, V. H.: "Postnatal changes in the pituitary-adrenal axis of the rat." *Proc. Soc. Exp. Biol. Med.* **128**: 269-272 (1968). F99,833/68

Review of earlier literature showing that the adrenal glands of the neonatal rat respond to various stressors in a normal manner, whereas at about seven days of age a period of comparative nonresponsiveness sets in. The present experiments reveal similar age-dependent variations in the adrenal reaction to ACTH or to partial adrenalectomy. "The fetal and early postnatal maintenance of the pituitary levels of ACTH could be the

result of a diffusion of CRF to the pituitary which becomes more difficult and fails with the growth and development of the rat. Thus the 7-day-old rat is showing signs of ACTH deficiency due to a failure of CRF to get to the pituitary gland." [The postulates concerning the role of CRF are purely hypothetical (H.S.).]

Dilman, V. M.: "Age-associated elevation of hypothalamic threshold to feedback control, and its role in development, ageing, and disease." *Lancet* June 12, 1971, pp. 1211-1219. H41,351/71

"It is suggested that the key process in the genetic programme of development and ageing is a gradual elevation of the threshold of sensitivity of the hypothalamus to feedback suppression." [Based mainly on speculative considerations (H.S.).]

J2,286/72

Nvota, J., Lamošová, D., Fáberová, A.: "Critical periods in the development of chicks." *Physiol. Bohemoslov.* **22**: 337-343 (1973).

J21,555/73

The stress of restraint during a critical period of about 3 to 4 weeks after hatching produced a maximal decrease in thyroid activity in adulthood and a significant drop in the BMR of the chick. "The critical phase for regulation of the function of the pituitary-adrenal and pituitary-gonad axis was found to be the period between the 15th and 21st day after hatching. Exposure to stress in this phase caused a significantly greater reaction of the adrenals to stress situations in the adult hens and significantly stimulated sexual maturation (egg-laying)."

Goldman, L., Winget, C., Hollingshead, G. W., Levine, S.: "Postweaning development of negative feedback in the pituitary-adrenal system of the rat." *Neuroendocrinology* **12**: 199-211 (1973).

H74,726/73

Given before ether or electroshock, "pretreatment with peripherally injected dexamethasone completely blocked a plasma corticosterone increase, in response to an ether and blood sampling stress in adults, but only partially reduced this response in weanlings. The failure of basal hypothalamic implants of corticoids to differentiate between ages in their ability to inhibit this stress response

supported the suggestion of extra-hypothalamic inhibitory systems as the loci of the deficit in weanlings."

Alexander, D. P., Britton, H. G., Nixon, D. A., Ratcliffe, J. G., Redstone, D.: "Corticotrophin and cortisol concentrations in the plasma of the chronically catheterised sheep fetus." *Biol. Neonate* **23**: 184-192 (1973).

J10,051/73

In chronically catheterized sheep fetuses, plasma ACTH levels were unusually high. Plasma cortisol was not strictly related to ACTH in individual samples but showed a high correlation in pooled data. The process of catheterization may have acted as a stressor.

Kral, V. A.: "Stress and senile psychosis." Proc. 5th World Congr. of Psychiatry, Mexico, D. F., 1971. *Int. Congr. Ser. No. 274*, pp. 331-337 (1973). J17,514/73

Resistance to stress decreases with age. Hormonal studies indicate, "firstly, that there is a decline in adrenocortical function with aging; and secondly, that patients suffering from organic psychoses of the senium, particularly senile dementia, show a tendency to a delayed adrenocortical overactivity, to ACTH stimulation as well as in stressful situations. It would appear, therefore, that cerebral pathology modifies the function of the adrenal cortex."

Wise, P. M., Frye, B. E.: "Functional development of the hypothalamo-hypophyseal-adrenal cortex axis in the chick embryo, *Gallus domesticus*." *J. Exp. Zool.* **185**: 277-291 (1973). J7,865/73

Studies on chick embryos, based mainly on plasma corticosterone determinations after stress produced by opening the shell and breaking one shank. "The adrenal exhibits significant autonomous functional capability prior to day 14, and the pituitary becomes important in maintaining both the resting level of hormone and the stress response between days 14 and 16 of incubation. The hypothalamus does not appear to control normal resting levels of corticosterone, but is essential for the stress response." The initial autonomy of the adrenal is demonstrated by the persistence of significant plasma corticosterone levels after decapitation of the embryo.

Dunn, J. D.: "Pituitary-adrenal function in adult androgenized female rats." *Proc. Soc. Exp. Biol. Med.* **146**: 75-77 (1974).

H87,171/74

Neonatal treatment with testosterone did not markedly affect the pituitary-adrenal response of female rats to ether stress in adult life.

Cote, T. E., Yasumura, S.: "Fluctuations in adrenal cyclic AMP levels in immature rats in response to ACTH and histamine stress." *Fed. Proc.* **33**: 205 (1974).

H83,812/74

Adrenal cyclic AMP levels were studied in six-day-old rats "subjected to treatment with either ACTH (50 mU/rat) or histamine dihydrochloride (0.2 mg/g body wt.). Untreated rats were used as controls in order to preclude the stress of vehicle injections. In 6-day-old rats, the values for adrenal cyclic AMP were: 3.35 pmol/mg in the untreated group; 4.35 pmol/mg in the histamine-treated group; and 37.03 pmol/mg 25 min. after injection of ACTH. The corresponding plasma corticosterone levels were 4.55 µg/100 ml in the untreated group; 5.13 µg/100 ml in the histamine-treated group; and 7.27 µg/100 ml in the ACTH-treated group. In 15-day-old rats, the values for adrenal cyclic AMP were: 4.60 pmol/mg in the untreated group; 45.1 pmol/mg in the histamine-stressed group; and 47.3 pmol/mg in the ACTH-treated group. The corresponding plasma corticosterone levels were: 4.58 µg/100 ml in the untreated group; 14.25 µg/100 ml in the histamine-stressed group; and 14.05 µg/100 ml in the ACTH-treated group." Apparently, the functional ACTH-sensitive adenyl cyclase system is present in rats by the sixth day after birth, but the presumably hypothalamic mechanism that controls stress-induced ACTH release is inoperative until the fifteenth day.

Müller, H. F., Grad, B.: "Clinical-psychological, electroencephalographic, and adrenocortical relationships in elderly psychiatric patients." *J. Gerontol.* **29**: 28-38 (1974).

J9,661/74

Cohen, A., Negellen, E.: "Changes in adrenal glands during stress in foetal rats." *Gen. Comp. Endocrinol.* **22**: 400-401 (1974).

H83,308/74

In fetal rats, subcutaneous formalin produces adrenal ascorbic acid depletion through stimulation of the hypothalamo-hypophyseal system, but only after the twentieth day of gestation. Ether anesthesia of adrenalectomized pregnant rats on the twentieth day of pregnancy increases the corticosterone content of fetal adrenals, but this can be pre-

vented by decapitation of the fetus, and by encephalectomy (ablation of the brain and hypothalamus, leaving the pituitary intact). "Ether acts as a stressor agent for the 20-day-old rat foetus."

→**STH.** Stubbe, P., Wolf, H.: "The effect of stress on growth hormone, glucose and glycerol levels in newborn infants." *Horm. Metab. Res.* **3**: 175-179 (1971).

H42,368/71

In full-term newborn infants, the stress of heel-pricks causes a decrease in blood STH whereas glucose and glycerol concentrations are increased, presumably as a consequence of catecholamine release. "The failure of the newborn infant to increase growth hormone concentration as do individuals during later life is evidence that adaptation of metabolic and hormonal reactions occurs during the postnatal period."

Fekete, M., Milner, R. D. G., Soltész, G., Assan, R., Mestyán, J.: "Plasma glucagon, thyrotropin, growth hormone and insulin response to cold exposure in the human newborn." *Acta Paediatr. Scand.* **61**: 435-441 (1972).

G92,222/72

In full-term and premature babies, exposure to cold caused no significant change in plasma insulin, glucagon, STH or TTH concentrations.

Shire, J. G. M.: "Growth hormone and premature ageing." *Nature* **245**: 215-216 (1973).

H78,587/73

In certain strains of dwarf mice, premature aging is associated with decreased STH production and depressed ^3H -thymidine uptake by several tissues, including the thymus. These dwarf mice are also deficient in other hormones, and not all strains show premature aging. Hence, "the altered uptake of thymidine in dwarf mice close to death could be caused by stress rather than by premature ageing."

→**Corticoids.** Selye, H., Albert, S.: "Age factor in responsiveness of pituitary and adrenals to folliculoids." *Proc. Soc. Exp. Biol. Med.* **50**: 159-161 (1942).

A37,751/42

In adult but not in immature rats, large doses of estradiol fail to cause pituitary or adrenal cortical hypertrophy.

Jailer, J. W.: "The maturation of the pituitary-adrenal axis in the newborn rat." *Endocrinology* **46**: 420-425 (1950).

B48,333/50

Adrenal ascorbic acid does not fall under the influence of EP in rats less than eight days old, nor in those exposed to cold before the age of sixteen days. However, ACTH causes adrenal ascorbic acid depletion even in rats aged four to six days. Earlier clinical observations have shown that human infants excrete glucocorticoids in response to severe trauma soon after birth, but the rat adrenal matures less rapidly than that of man.

Rinfret, A. P., Hane, S.: "Depletion of adrenal ascorbic acid following stress in the infant rat." *Endocrinology* **57**: 497-499 (1955).

B29,292/55

In four- to seven-day-old rats, adrenal ascorbic acid depletion in response to a stressor (laparotomy) is the same as in more mature animals, and occurs between two and six hours following initiation of stress.

Grad, B., Kral, V. A.: "Adrenal cortical stress effects in senility. II. The response to heat stimulation produced by the Hardy-Wolff-Goodell dolorimeter." *Can. Psychiatr. Assoc. J.* **6**: 66-74 (1961).

J10,361/61

Hockman, C. H.: "Prenatal maternal stress in the rat: its effects on emotional behavior in the offspring." *J. Comp. Physiol. Psychol.* **54**: 679-684 (1961).

J23,011/61

Biochemical changes produced in the offspring of rats exposed to psychogenic stress during pregnancy are explained tentatively in terms of increased secretion of endocrine substances.

Schapiro, S.: "Pituitary ACTH and compensatory adrenal hypertrophy in stress-non-responsive infant rats." *Endocrinology* **71**: 986-989 (1962).

D45,372/62

In newborn rats, adrenal ascorbic acid depletion and corticosterone synthesis fail to occur under the influence of stressors, but unilateral adrenalectomy causes pronounced compensatory hypertrophy of the contralateral gland.

Schapiro, S., Geller, E., Eiduson, S.: "Neonatal adrenal cortical response to stress and vasopressin." *Proc. Soc. Exp. Biol. Med.* **109**: 937-941 (1962).

D24,932/62

In rats, electroshock (unlike natural or synthetic vasopressin) fails to elicit the usual ascorbic acid depletion and increase the corticosterone concentration of the adrenal cortex during the first eight days of life. This "stress-non-responsive period" is ascribed to "immaturity of the hypothalamic osmoreceptor mechanism which underlies adjustments in vasopressin secretion."

Cuny, G., Duheille, J., Guerci, O., Tenette, M.: "Elimination des 17 O.H. et stress chirurgical chez les vieillards" (Elimination of 17-hydroxycorticosteroids and surgical stress in the aged). *Rev. Franç. Gérontol.* 8: 391-399 (1962). J24,006/62

Milković, K., Milković, S.: "Functioning of the pituitary-adrenocortical axis in rats at and after birth." *Endocrinology* 73: 535-539 (1963). E31,802/63

The ascorbic acid content of the adrenals fell in rats at birth, but returned to embryonic levels on the first or second day of life. Subsequently there was a precipitous decrease followed by a secondary rise by the tenth day. Plasma corticosterone levels dropped slightly after birth. Intravenous EP, used as a stressor in newborn rats immediately after birth, did not deplete adrenal ascorbic acid. However, stress increased plasma corticosterone prenatally and at birth, but then not again until the fourteenth postnatal day.

Schapiro, S., Geller, E.: "Fetal-maternal adrenal cortical response to stress in the intact and hypophysectomized rat." *Endocrinology* 74: 737-741 (1964). F9,485/64

Histamine or surgical trauma applied to pregnant hypophysectomized rats produced no adrenal corticosterone or ascorbic acid depletion such as was found in intact controls. The fetuses revealed no evidence of adrenocortical stimulation, irrespective of whether the mother was intact or hypophysectomized when exposed to the stressors.

Daikoku, S., Saijo, S.: "Volumetrical observation on the influence of maternal sham hypophysectomy on the fetal adrenal gland." *Endocrinol. Jap.* 11: 55-61 (1964).

F12,069/64

Sham hypophysectomy in pregnant rats increases corticoid secretion, and the latter crosses the placental barrier, inhibiting the development of the fetal adrenal.

Bowman, R. E., Wolf, R. C.: "Plasma 17-OHCS response of the infant rhesus monkey to a noninjurious, noxious stimulus." *Proc. Soc. Exp. Biol. Med.* 119: 133-135 (1965).

F42,116/65

In two-day-old rhesus monkeys, centrifugation caused elevations in the nonconjugated 17-OHCS content of the plasma, but this effect was not as marked as that obtained with ACTH, "suggesting either that the restraint and rotation was not sufficiently

stressful or that the infant CNS-hypophyseal axis was not sufficiently developed to stimulate fully the adrenal cortex."

Baca, Z. V., Chiodi, H.: "Developmental changes in the size and ascorbic acid content of the adrenals of white rats." *Endocrinology* 76: 1208-1212 (1965). F41,308/65

In rats, the adrenal weight per 100 gm. body weight decreases during the last few days of prenatal and the first days of postnatal life, reaching a maximum by the twentieth day and then declining to the adult level which remains stable until old age. The vitamin C content of the fetal adrenal increases in the last days of pregnancy, showing an abrupt fall in the four days after birth, and then remaining low until the twelfth day. Adult values are reached around the seventieth day of life. The perinatal changes are ascribed to the stress of adaptation to extrauterine life.

Schapiro, S.: "Androgen treatment in early infancy: effect upon adult adrenal cortical response to stress and adrenal and ovarian compensatory hypertrophy." *Endocrinology* 77: 585-587 (1965). F49,822/65

One-day-old female rats given 1 mg. testosterone subsequently developed the expected persistent estrus syndrome. The response to stress (ether) was normal in both sexes although the extent of compensatory adrenal hypertrophy appeared to be less after testosterone pretreatment. An addendum notes that "neonatal treatment with 1 mg cortisol has been subsequently observed to produce a fertile 'corticoid runt' with a normal adrenal cortical response to stress."

Haltmeyer, G. C., Denenberg, V. H., Thatcher, J., Zarrow, M. X.: "Response of the neonatal rat after subjection to stress." *Nature* 212: 1371-1373 (1966).

F74,906/66

During the first five days of life, the stress of heat or electric shock raises the adrenal and plasma concentration of corticosterone in the rat. Manifestly, the neonatal rat adrenal can respond normally to stressors by increased synthesis and release of corticoids. These data contradict earlier reports of a "stress-non-responsive period" in this species. With adrenal ascorbic acid depletion used as an indicator, the situation appears to be different, and reactivity also depends upon the stressor (20 refs.).

Grad, B., Kral, V. A., Payne, R. C., Berenson, J.: "Adrenal cortical function in the psy-

chooses of later life." *Laval Méd.* **37**: 126-134 (1966). G37,699/66

There were no significant differences in plasma cortisol and corticosterone levels between male and female, normal and senile psychotic patients. However, normal men showed significantly higher urinary corticoid excretion than psychotics. This difference was less obvious in women.

Mozhaev, V. I.: "The glucocorticoid function of the adrenal cortex in the postoperative period in aged patients." *Vestn. Khir.* **97** No. 8: 55-62 (1966) (Russian).

J23,733/66

In aged patients, surgical stress produces a subnormal discharge of glucocorticoids.

Levine, S.: "Maternal and environmental influences on the adrenocortical response to stress in weanling rats." *Science* **156**: 258-260 (1967). F82,015/67

Adrenocortical steroids in the plasma of newborn rats were reduced at weaning after the pups "were exposed to novel stimuli as compared with controls that were not handled."

Zarrow, M. X., Denenberg, V. H., Halmeyer, G. C., Brumaghim, J. T.: "Plasma and adrenal corticosterone levels following exposure of the two-day-old rat to various stressors." *Proc. Soc. Exp. Biol. Med.* **125**: 113-116 (1967). F80,161/67

Even in two-day-old rats, ACTH, histamine, electroshock, heat and cold increase the plasma and adrenal corticosterone levels of both sexes. Only tight ligature above the knee joint is ineffective at this age, perhaps as Fortier suggested, because neural stressors (pain) act through a different pathway. Presumably the pituitary-adrenal axis is operative in the two-day-old rat but "the neural component in the system is not active as yet." Contradictions in the earlier literature on the responsiveness of the neonatal pituitary are analyzed.

Schäfer, K. H.: "Das reife Neugeborene" (The mature newborn infant). *Arch. Gynäekol.* **204**: 137-151 (1967). F80,470/67

The blood corticoid level in newborn infants rises sharply during the first two days, and this is associated with other manifestations of "birth stress" which are most intense in cases of difficult deliveries.

Denenberg, V. H., Brumaghim, J. T., Halmeyer, G. C., Zarrow, M. X.: "Increased

adrenocortical activity in the neonatal rat following handling." *Endocrinology* **81**: 1047-1052 (1967). F89,864/67

Handling two-day-old rats increased their plasma corticosterone levels within half an hour after they were returned to their mothers. However, this response could be prevented if the pups were placed in handling cans maintained at 35.5°C.

Kral, V. A., Grad, B., Payne, R. C., Berenson, J.: "The effect of ACTH on the plasma and urinary corticoids in normal elderly persons and in patients with senile psychosis." *Am. J. Psychiatry* **123**: 1260-1269 (1967).

G45,322/67

In patients with senile psychosis, the rise in plasma cortisol and corticosterone levels following exposure to physical and psychologic stressors was excessive, but their response to ACTH remained within normal limits. This "might have its cause in a dysfunction of either the pituitary or the hypothalamus or both."

Ader, R., Friedman, S. B., Grota, L. J., Schaefer, A.: "Attenuation of the plasma corticosterone response to handling and electric shock stimulation in the infant rat." *Physiol. Behav.* **3**: 327-331 (1968).

H5,148/68

In rats eight, fifteen and twenty-one days old, stressor-induced elevations of plasma corticosterone were first seen at fifteen days, at which time the responses to handling and electric shock were similar. Twenty-one-day-old unmanipulated rats showed a greater reaction to electric shock than to handling. Previously shocked animals displayed little adaptation, whereas repeated handling diminished the plasma corticosterone response.

Cathro, D. M., Forsyth, C. C., Cameron, J.: "Adrenocortical response to stress in newborn infants." *Arch. Dis. Child.* **44**: 88-95 (1969). G65,468/69

In both full-term and premature newborn infants, various incidental stressors (asphyxia, respiratory distress) generally produced the expected increase in urinary corticoid excretion. This relationship was not significant, however, in dysmature (light-for-dates) infants. The somewhat contradictory pertinent literature is reviewed.

Grad, B., Kral, V. A.: "The delayed effect of ACTH administration on the plasma corticoid level of normal elderly persons and pa-

tients with chronic brain syndrome." *J. Am. Geriatr. Soc.* **17**: 15-24 (1969).

H6,490/69

Patients with senile or arteriosclerotic brain syndrome are more reactive to stress than are normal aged subjects. Their adrenal cortices are more responsive to ACTH.

Hess, G. D., Riegle, G. D.: "Adrenocortical responsiveness to stress and ACTH in aging rats." *J. Gerontol.* **25**: 354-358 (1970).

G78,322/70

Following exposure to ether vapors or exogenous ACTH, old rats showed significantly lower plasma corticosterone levels than young controls.

H67,112/73

Young and old rats were subjected to repeated restraint for twenty days. The decrease in stress responsiveness was greater in the former than in the latter groups.

- Observations on women exposed to various stressors show that "the regulation of fetal plasma FFA is controlled by the same mechanisms as those of the pregnant adult. The fetus is however, unable to respond to a high plasma glucose concentration as the pregnant woman does (i.e., by a decrease in plasma FFA concentration). This difference is probably due to a limited supply of fetal insulin and/or to the saturation of the en-

zyme systems synthesizing lipids in fetal tissues. Pathologic conditions of gestation and stresses in utero have no effect on the fetal plasma FFA concentrations. This is considered as an expression of fetomaternal homeostatic ability. Increase in fetal plasma FFA concentrations takes place after birth."

Danilova, L. Y.: "The role of adrenal glands in the regulation of carbohydrate metabolism of undercooled animals having different degrees of thermoregulation." *Acta Biol. Med. Ger.* **21**: 625-634 (1968) (Russian). H7,143/68

In various premature but not in mature newborn mammals, cooling is not accompanied by glycogenolysis owing to insufficient EP secretion. Glucocorticoids raise the hepatic glycogen reserves in newborns, but fail to increase their resistance to hypothermia.

Groza, P., Buzoianu, V., Ionescu, S., Bogatu, D.: "Uropepsinogen reaction in surgical stress in terms of age." *Rev. Roum. Physiol.* **6**: 203-206 (1969). H18,402/69

In elderly patients, operative stress causes a fall in uropepsinuria which is not obvious in younger subjects. "Uropepsin assay may represent a functional test for post-traumatic reactivity."

Yuwiler, A., Geller, E., Schapiro, S.: "Effect of neonatal corticoids on tryptophan pyrrolase and brain serotonin." In: Németh, S., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 215-228. Bratislava: Slovak Academy of Sciences, 1973. E10,470/73

In newborn rats, a single injection of cortisol induces tryptophan pyrrolase and diminishes both body growth and the 5-HT content of the brain. These results are discussed in relation to the function of tryptophan in stress.

Brooke, O. G., Harris, M., Salvosa, C. B.: "The response of malnourished babies to cold." *J. Physiol. (Lond.)* **233**: 75-91 (1973). J5,659/73

Malnourished Jamaican children failed to raise their heat production and their rectal temperatures fell, when the ambient temperature decreased from 28° to 25°C.

Clapp, J. F., Patel, N., Abrams, R. M.: "Fetal metabolic response to surgical stress" (abstracted). *Physiologist* **17**: 196 (1974). H89,878/74

In lamb fetuses, surgical stress elicits changes in oxygen and glucose utilization, lactate production and amino acid uptake.

→**Morphology.** Hoagland, H., Bergen, J. R., Bloch, E., Elmadjian, F., Gibree, N. R.: "Adrenal stress responses in normal men." *J. Appl. Physiol.* **8**: 149-154 (1955). C12,916/55

Manipulation of the Hoagland-Werthessen pursuit meter was used as a stress test. Young men (sixteen to twenty years) "appear to call very little on adrenal cortical mechanisms to meet stresses which enhance adrenocortical responses of older men." Eosinopenia correlates better with urinary excretion of EP than with 17-KS excretion, regarded as indicators of adrenocortical activity.

Brodie, D. A., Hanson, H. M.: "A study of the factors involved in the production of

gastric ulcers by the restraint technique." *Gastroenterology* **38**: 353-360 (1960).

C87,271/60

Young rats are more predisposed to stress-induced gastric ulcers than are old rats.

Wilson, T. R.: "Age and susceptibility to gastric ulceration in male and female rats." *Gerontologia* (Basel) **12**: 226-230 (1966).

F78,288/66

Young rats are much more susceptible to restraint-induced gastric ulcers than adults.

Krakowski, A. J.: "Psychophysiologic gastrointestinal disorders in children." *Psychosomatics* **8**: 326-330 (1967). F91,348/67

The most common stress-induced gastrointestinal disorders in children are gastritis, peptic ulcer, ulcerative colitis and diarrhea.

Heim, T., Kellermayer, M.: "The effect of environmental temperature on brown and white adipose tissue in the starving newborn rabbit." *Acta Physiol. Acad. Sci. Hung.* **31**: 339-346 (1967). G50,688/67

The effect of stress upon fat mobilization was studied in newborn rabbits starved to death at different environmental temperatures. "Brown fat is mobilized in response to cold but not during starvation in a thermoneutral environment, whereas white fat apparently serves as a general metabolic reserve and is used during starvation both in the absence and the presence of a cold-induced increase in heat production."

Rassaert, C. L., Steinert, B. G.: "Influence of inanition and cold exposure on biological age of rat tail tendon collagen." *Proc. Soc. Exp. Biol. Med.* **128**: 789-793 (1968).

H2,015/68

In rats, reduction of food supply caused changes typical of the G.A.S., as well as increases in isometric tail tendon contraction indicative of premature aging. However, exposure to cold elicited no such alterations in collagen contractility.

Sultz, H. A., Schlesinger, E. R., Feldman, J. G., Mosher, W. E.: "The epidemiology of peptic ulcer in childhood." *Am. J. Public Health* **60**: 492-498 (1970).

J8,025/70

Peptic ulcers are far more common during childhood than had been suspected. Often, marital difficulties between parents are the cause of this stress reaction.

Grezicka-Filus, B., Socha, J., Bittner, K.:

"Psychological aspects of peptic ulcer in children." *Pediatr. Pol.* **45**: 821-826 (1970).

J23,588/63

Schaefer, T. Jr.: "Early 'experience' and its effects on later behavioral processes in rats: II. A critical factor in the early handling phenomenon." *Trans. N.Y. Acad. Sci.* **25**: 871-889 (1963). J23,586/63

Handling is effective in reducing later emotionality in the life of a rat, but only if applied very early. This study implies that "handling is ineffective unless it is accompanied by a temperature change." In fact, lowering the ambient temperature at the same early period of life produces an equal effect.

Lieberman, M. W.: "Early developmental stress and later behavior." *Science* **141**: 824-825 (1963). E24,883/63

"The effects of behavioral stress on mice during pregnancy on the behavior of offspring are mimicked by epinephrine injection of mice during pregnancy; hydrocortisone and norepinephrine injection also produce behavioral changes in the offspring. Similar results were obtained in chicks hatched from injected eggs." Presumably, "injection of stress-syndrome hormones into pregnant mice and into chicken eggs produce changes similar to those produced by subjecting pregnant mice to a behavioral stressor."

Hutchings, D. E.: "Early 'experience' and its effects on later behavioral processes in rats: III. Effects of infantile handling and body temperature reduction on later emotionality." *Trans. N.Y. Acad. Sci.* **25**: 890-901 (1963). J23,587/63

Confirmatory evidence that handling during the immediate postnatal period decreases

emotionality in rats only because of the associated drop in temperature.

E666/67

A monograph on the traumatic and psychic problems of senility with special reference to the G.A.S.

Kral, V. A., Grad, B., Berenson, J.: "Stress reactions resulting from the relocation of an aged population." *Can. Psychiatr. Assoc. J.* **13**: 201-209 (1968). *G58,342/68*

In subjects relocated to homes for the aged, plasma corticoids increased, especially among men who developed organic signs of disease. Of the normal men, 25 percent died within six months of relocation, while all normal women survived. More psychotics died than normal subjects.

Chapouthier, G., Legrain, D., Spitz, S.: "Stress' de la mère gravide et capacités d'apprentissage des jeunes souris" ("Stress" in the pregnant mother and learning capacity of young mice). *C.R. Acad. Sci. (Paris)* **269**: 504-506 (1969). *J21,283/69*

Porter, R. H., Wehmer, F.: "Maternal and infantile influences upon exploratory behavior and emotional reactivity in the albino rat." *Dev. Psychobiol.* **2**: 19-25 (1969).

J19,542/69

In rats, "1. both offspring infantile handling and maternal pregnancy stress tend to increase adult exploratory behavior; 2. adult weight was lower for subjects whose mother had undergone stress during pregnancy than for offspring of non-stress females; 3. several 2-way interactions were found to significantly influence open-field exploration; 4. when offspring infantile handling was combined with maternal pregnancy stress, emotional reactivity (i.e., defecation) was found to increase

significantly over that following either type of stimulation alone."

Tallmer, M., Kutner, B.: "Disengagement and the stresses of aging." *J. Gerontol.* **24**: 70-75 (1969). G65,232/69

Stressors associated with aging, such as ill health, widowhood and retirement, produce "disengagement" which is a gradual withdrawal from society.

Moore, T.: "Stress in normal childhood." *Hum. Relat.* **22** No. 3: 235-250 (1969). E67,152/69

Effects of psychologic stressors upon the mentality of children, including neonates.

Wehmer, F., Porter, R. H., Scales, B.: "Pre-mating and pregnancy stress in rats affects behaviour of grandpups." *Nature* **227**: 622 (1970). H27,899/70

Rats whose grandmothers were exposed to avoidance conditioning before mating or to conditioned stress during pregnancy were more active in the common open test field than were the descendants of nondisturbed control grandmothers. Apparently, "stress before or during pregnancy, like infantile handling, can influence the behaviour of future generations, beyond the immediate offspring of the manipulated females."

Markus, E., Blenkner, M., Bloom, M., Downs, T.: "Relocation stress and the aged." In: Blumenthal, H. T., *The Regulatory Role of the Nervous System in Aging*, pp. 60-71. Basel, München, and New York: S. Karger, 1970. E8,832/70

Relocation of aged persons from an accustomed to an unknown environment increases morbidity and mortality because it "generates stress and discomfort which call forth coping responses from the relocated person beyond those required by familiar routines." Relocation is particularly damaging to males, especially those with severe mental dysfunctions.

Howard, E.: "Increased reactivity and impaired adaptability in operant behavior of adult mice given corticosterone in infancy." *J. Comp. Physiol. Psychol.* **85**: 211-220 (1973). J6,970/73

"Intensive corticosterone treatment given to mice in the first postnatal week irreversibly decreases growth and DNA synthesis in the brain." After early hypercorticism, adult mice become hyperresponsive when working for food and show impaired ability to adapt to schedule changes.

Ressler, R. H., Anderson, L. T.: "Avoidance conditioning in mice as a function of their mothers' exposure to shock." *Dev. Psychobiol.* **6**: 105-111 (1973).

H80,110/73

Kral, V. A.: "Psychiatric problems in the aged: a reconsideration." *Can. Med. Assoc. J.* **108**: 584-590 (1973). H65,964/73

Among the numerous mental disorders found in senile people, "only two direct relationships are seen: the acute confusional states due to the age-linked decline in stress resistance; and the neurotic reactions due to the diminished capacity for rapid and adequate adjustment to the more subtle but chronic sociopsychological changes the aged individual is so frequently exposed to in our society."

Johnston, R. E., Miya, T. S., Paolino, R. M.: "Facilitated avoidance learning and stress-induced corticosterone levels as a function of age in rats." *Physiol. Behav.* **12**: 305-308 (1974). J11,624/74

"Older animals acquired the conditioned avoidance response (CAR) faster and required a longer time to extinguish, than the younger animals. The enhanced CAR performance of the older animals could not be attributed to an altered pain threshold but

was correlated with a significantly higher plasma corticosterone response to ether-stress. The data are interpreted as being consistent with the notion of a positive relationship between pituitary-adrenal activity and facilitated avoidance learning."

←**Pre- and Perinatal Stress in General**
(excluding Handling, Retirement and specific changes previously mentioned). Weininger, O.: "Mortality of albino rats under stress as a function of early handling." *Can. J. Psychol.* **7**: 111-114 (1953). B93,807/53

None of the rats gentled ten minutes daily for about ten days after weaning died when exposed to a complex stressor situation (cold, starvation and water deprivation) in adulthood, but the same procedure applied at the same time in adulthood to nongentled controls caused adrenal enlargement, bleeding gastric erosions and other manifestations of the alarm reaction, as well as a high mortality rate.

Weininger, O.: "Physiological damage under emotional stress as a function of early experience." *Science* **119**: 285-286 (1954). B91,063/54

Recently weaned rats were gentled by mild handling and caressing for three weeks. When later exposed to restraint, they were more resistant as indicated by body weight, manifestations of fear, gastrointestinal and cardiovascular lesions and by reduced adrenal hypertrophy.

Christian, J. J.: "A review of the endocrine responses in rats and mice to increasing population size including delayed effects on offspring." *Naval Med. Res. Inst.* August 6, 1957, pp. 443-462. C53,409/57

Rats and mice living under crowded conditions show many manifestations of stress, including a decrease in fertility which may act as a regulator of population density to maintain an optimal level. Crowding can also cause lasting changes in the offspring of surviving females, probably due to lactational deficiencies.

Soiva, K., Grönroos, M., Aho, A. J.: "Effect of audiogenic-visual stimuli on pregnant rats." *Ann. Med. Exp. Fenn.* **37**: 464-470 (1959). C97,217/59

In the offspring of rats exposed to audio-visual stress during pregnancy, the average weight of the body as a whole and of the adrenals, pituitary, ovaries and heart was essentially unchanged, but there was some

renal enlargement and a slight increase in blood pressure.

 Female rats repeatedly restrained one week before conception gave birth to significantly fewer males and smaller litters than did unstressed controls.
- Curtis, S. E.: "Responses of the piglet to perinatal stressors." *J. Anim. Sci.* **38**: 1031-1036 (1974). J21,586/74
 Evidence reviewed suggests that stress from the prenatal respiratory-gas environment is directly related to intrapartal stillbirth and reduced neonatal survivability and that stress from the postnatal thermal environment is very likely related directly and indirectly to neonatal mortality in the piglet."
- Krauss, A. N., Auld, P. A. M.: "Intrauterine stress and pulmonary maturation." *J. Pediatr.* **85**: 880 (1974). J22,675/74
 Phelps, D. L.: "Intrauterine stress and pulmonary maturation." *J. Pediatr.* **85**: 879-880 (1974). J22,674/74
 "The data do not support the hypothesis that intrauterine stress leads to increased lung maturity."
- Gorsuch, R. L., Key, M. K.: "Abnormalities of pregnancy as a function of anxiety and life stress." *Psychosom. Med.* **36**: 352-362 (1974). J19,154/74
 Studies on 118 women at a low-income clinic "indicated that anxiety around the first trimester was related to abnormalities of pregnancy, parturition and infant status. Life stress during the second and third trimesters was similarly associated with the same measure of abnormalities" (23 refs.).
- Smith, D. J., Joffe, J. M., Heseltine, G. F. D.: "Modification of prenatal stress effects in rats by adrenalectomy, dexamethasone and chlorpromazine." *Fed. Proc.* **33**: 223 (1974). H83,859/74
 Adrenalectomy and treatment of pregnant rats with chlorpromazine or dexamethasone can prevent or modify the prenatal effects produced by stress in the offspring. [The brief abstract is difficult to evaluate (H.S.).]
- Bell, R. W., Nitschke, W., Bell, N. J., Zachman, T. A.: "Early experience, ultrasonic vocalizations, and maternal responsiveness in rats." *Dev. Psychobiol.* **7**: 235-242 (1974). J12,730/74
 In neonatal rats, exposure to cold and several other stressors induces ultrasonic vocalization and agitation of their mothers. "If the pup is mildly stressed he displays a pattern of ultrasonic signaling which elicits adaptive maternal responsiveness. If the pup is too severely stressed he displays persistent signaling which agitates the mother, preventing an adaptive pattern of behavior, and resulting in a prolonged response to stress in the pup."
- Trojan, S., Jilek, L., Staudacherova, D., Travníčkova, E.: "Adaptation of rats to repeated aerogenic hypoxia in early postnatal ontogenesis and adulthood." *Physiol. Bohemoslov.* **23**: 199-209 (1974). J14,696/74
 Comparative observations on adaptation to hypoxia in newborn and adult rats, with special reference to the G.A.S.

Genazzani, A. R., Cocola, F., Nasi, A., Neri, P., Fioretti, P.: "Endocrinological monitoring of late pregnancy: HCS plasma levels and chronic fetal distress." *J. Nucl. Biol. Med.* **18**: 60-66 (1974). J16,740/74

In human embryos, pre-eclampsia, severe eclampsia, feto-placental dystrophy, multiple placental infarcts and prolonged pregnancy allegedly produce "chronic fetal distress" with a diminution of human chorionic STH in the mother's blood. The manifestations of this condition are that the baby is small, shows fetal dystrophy and/or marked skin dryness at delivery.

←Prenatal Stress Conducive to Malformations or Stillbirths. Yokobori, K.: "Experimental studies of noise stimulation effects on congenital malformation." *J. Otolaryngol. Jap.* **62**: 69-81 (1956). J24,385/56

Strean, L. P., Peer, L. A.: "Stress as an etiologic factor in the development of cleft palate." *Plast. Reconstr. Surg.* **18**: 1-8 (1956). D7,329/56

Among 232 cases of cleft palate, the maternal case histories revealed a high incidence of stress (emotional, traumatic, infectious) at the time when the maxillae of the embryo are expected to fuse. This phenomenon is ascribed to increased cortisol production around the sixtieth day of pregnancy and is discussed in terms of the G.A.S. concept.

Ingalls, T. H.: "Causes and prevention of developmental defects." *J.A.M.A.* **161**: 1047-1051 (1956). C27,896/56

In mice, hypoxia applied as a standard stressor during pregnancy leads to a variety of malformations in the offspring. There is evidence that a similar situation exists in women.

Runner, M. N.: "Embryocidal effect of handling pregnant mice and its prevention with progesterone" (abstracted). *Anat. Rec.* **133**: 330-331 (1959). D98,022/59

Ishii, H., Yokobori, K.: "Experimental studies on teratogenic activity of noise stimulation." *Gunma J. Med. Sci.* **9**: 153-167 (1960). G98,756/60

Mice exposed to noise during early pregnancy give birth to an increased number of malformed newborns.

Härtel, A., Härtel, G.: "Experimental study of teratogenic effect of emotional stress in rats." *Science* **132**: 1483-1484 (1960). J22,939/60

In rats, although restraint during the ninth to twelfth days of pregnancy produced no malformations, it increased the teratogenic effect of vitamin A.

Warkany, J., Kalter, H.: "Maternal impressions and congenital malformations." *Plast. Reconstr. Surg.* **30**: 628-637 (1962). J23,642/62

In mice, audiogenic stress applied during pregnancy, unlike cortisone, does not produce cleft palate or other malformations in the offspring.

Caldwell, D. F.: "Stillbirths from adrenal demedullated mice subjected to chronic stress throughout gestation." *J. Embryol. Exp. Morphol.* **10**: 471-475 (1962). J23,452/62

In mice, psychogenic stress applied during pregnancy increases the incidence of stillbirth, but this effect is largely prevented by demedullation of the adrenals.

Goldman, A. S., Yakovac, W. C.: "The enhancement of salicylate teratogenicity by maternal immobilization in the rat." *J. Pharmacol. Exp. Ther.* **142**: 351-357 (1963). E35,710/63

Fraser, F. C., Warburton, D.: "No association of emotional stress or vitamin supplement during pregnancy to cleft lip or palate in man." *Plast. Reconstr. Surg.* **33**: 395-399 (1964) (16 refs.). G13,856/64

Nemets, N. M.: "Analysis of the characteristics and significance of changes in internal environment of the body during pregnancy." *Biull. Éksp. Biol. Med.* **55** No. 2: 45-49 (1963) (Russian). Eng. transl.: *Fed. Proc.* **23**: 401-403 (1964). F5,962/64

Pregnant rabbits with experimental neuroses often aborted or gave birth to immature progeny (23 refs.).

Ishii, H., Kimura, K., Harada, O.: "Stress and auditory characteristics of the rat." *Ann. Otol. Rhinol. Laryngol.* **73**: 948-956 (1964). G27,159/64

Studies on the teratogenic effect of noise applied during pregnancy in various species.

Jaworska, M., Reszke, S., Kawiak, H.: "Attempted analysis of the etiology of cleft-palate, based on 438 cases." *Pol. Tyg. Lek.* **19**: 1517-1519 (1964) (Polish). J24,122/64

The mothers of children born with cleft palate are frequently undernourished and have been exposed simultaneously to psychic

or somatic injuries. "These two factors (i.e. undernourishment and psychic or physical trauma) are still not definitely proved to be teratogenic for the human embryo. It seems however, that they should be treated as such, and ought to be included into the problem of general prophylaxis in the pregnant woman."

Drillien, C. M., Wilkinson, E. M.: "Emotional stress and mongoloid births." *Dev. Med. Child Neurol.* **6**: 140-143 (1964).
J23,843/64

Cizkova, J.: "Prenatal endocrine influences on the foetus and their relation to late behaviour." *Clin. Dev. Med.* No. 19: 10-13 (1965). G66,783/65

A statistical study on a small sample of mongoloid children in Prague suggests that emotional stress during pregnancy predisposes the embryo to this disease.

Rosenzweig, S.: "Psychological stress in cleft palate etiology." *J. Dent. Res.* **45** Supp. 6: 1585-1593 (1966). J22,586/66

Geber, W. F.: "Developmental effects of chronic maternal audiovisual stress on the rat fetus." *J. Embryol. Exp. Morphol.* **16**: 1-16 (1966). G40,642/66

When pregnant rats were exposed to audiovisual stress, many of their litters were absorbed, while others exhibited developmental abnormalities which "included interparietal meningocele, abdominal hernia (omphalocele), spina bifida, and defects of the eye, tail, hind- and forefoot. Hematomas, varying in size and location, were found throughout the cranial area. Localized hematomas were found in the sublingual areas. Osteogenic effects, ranging from partial to complete inhibition, were widespread." These changes may be due to an "imbalance of the maternal autonomic neurohormone and hypothalamic-pituitary-adrenal relationships."

Kosmachevskaia, E. A., Chebotar, N. A.: "Damaging action of 4-methyluracil upon the embryogenesis of rats under stress to which the maternal organism is exposed." *Bull. Éksp. Biol. Med.* **66** No. 12: 89-92 (1968) (Russian). H34,247/68

Bloch, S.: "Beobachtungen über den Einfluss einiger vor der Gravidität applizierter Traumata auf die nachfolgende Trächtigkeit bei der Laboratoriums-Maus. I. Mitteilung" (Observations on the effect of various traumas applied before pregnancy on subsequent pregnancy in the laboratory mouse. Report

I). *Gynaecologia* (Basel) **166**: 361-368 (1968). H5,092/68

Various stressors (crowding, restraint), applied to female mice just before impregnation, "resulted partly in death of the animals, abortion and stillbirths," and in impaired growth and development of the young of the following gestation.

Bloch, S., Rippmann, E. T.: "Untersuchungen über den Einfluss verschiedener Traumata auf die Gravidität bei der Laboratoriums-Maus" (Studies on the influence of various psychic traumas on pregnancy in the laboratory mouse). *Z. Psychosom. Med.* **14**: 33-45 (1968). G57,334/68

Various stressors applied during pregnancy interfere with the development of the embryo.

Euker, J. S., Riegle, G. D.: "Effects of stress on pregnancy in the rat." *J. Reprod. Fertil.* **34**: 343-346 (1973). H74,642/73

In rats exposed to restraint or surgical trauma during pregnancy, embryonic mortality is increased.

Hamburgh, M., Lang, A., Rader, M., Silverstein, H., Hoffman, K., Miller, D., Lynch, B.: "Teratogenesis in offspring of stress mice." *Acta Univ. Carol. Med. (Praha)* **56-57**: 235-237 (1973). H91,749/73

Geber, W. F.: "Inhibition of fetal osteogenesis by maternal noise stress." *Fed. Proc.* **32**: 2101-2104 (1973). H78,365/73

Endl, J., Schaller, A.: "Missbildungshäufigkeit unter Neugeborenen von Gastarbeiterinnen" (Frequency of malformation in newborn infants of foreign women working in Germany). *Wien Klin. Wochenschr.* **85**: 718-720 (1973). H78,590/73

There appears to be a comparatively high malformation rate in newborn infants of foreign women working in Germany. Arguments are discussed which suggest this to be a consequence of various stressors related to relocation.

Bellvé, A. R.: "Development of mouse embryos with abnormalities induced by parental heat stress." *J. Reprod. Fertil.* **35**: 393-403 (1973). H80,601/73

Exposure of pregnant mice to heat (34.5°C) caused abnormalities and high mortality among their embryos, presumably as a consequence of stress.

Zakem, H. B., Alliston, C. W.: "The effects of noise level and elevated ambient temperatures upon selected reproductive traits in female Swiss-Webster mice." *Lab. Anim. Sci.* **24**: 469-475 (1974).

J13,928/74

Exposure to noise or heat on the fifth day of gestation significantly reduced the number, size and weight of embryos in mice, but combined treatment with these stressors was not uniformly additive (17 refs.).

Saxén, I.: "Cleft lip and palate in Finland: parental histories, course of pregnancy and selected environmental factors." *Int. J. Epidemiol.* **3**: 263-270 (1974). J20,848/74

Hamburgh, M., Mendoza, L. A., Rader, M., Lang, A., Silverstein, H., Hoffman, K.: "Malformations induced in offspring of crowded and parabiotically stressed mice." *Teratology* **10**: 31-37 (1974). J15,934/74

Malformations were induced in fetuses of mice kept under crowded conditions or parabiotically joined during pregnancy. "The abnormalities included amputation of peripheral limb structures, open neural folds, exencephaly, blisters, head, face, and tail malformation, and generalized growth retardation. The hypothesis that the teratogenic and other effects were consequences of prolonged prenatal stress induced by the experimental conditions is supported by the observation that both procedures led in a short time to significant increases in mean maternal adrenal weight."

Boyd, I. E., Chamberlain, G. V. P., Ferguson, I. L. C.: "The oxytocin stress test and the isoxsuprime placental transfer test in the management of suspected placental insufficiency." *J. Obstet. Gynaecol. Br. Commonw.* **81**: 120-125 (1974). J14,783/74

Of women who had an "oxytocin stress test" during pregnancy, several gave birth to babies with various functional or morphologic defects, whereas others had normal babies. Clearly, the oxytocin stress test does not adequately measure placental sufficiency.

Bal'magiiia, T. A., Surovtseva, Z. F.: "Growth pattern of rabbit fetuses during normal pregnancy and with inhibition of the 'gestation dominant.'" *Bull. Éksp. Biol. Med.* **77**: No. 4: 44-47 (1974) (Russian). Engl.

transl.: *Bull. Exp. Biol. Med.* **77**: 384-387 (1974). J24,300/74

In rabbits, exposure to stress (sound, electroshock) "in the embryonic period and also to some extent in the embryonic-fetal periods thus gives rise to death of the fetuses, whereas exposure in the early stages of the fetal period leads to their delayed growth. Exposure to stress on the 25th-27th day of pregnancy evidently leads to strengthening of the gestation dominant, as is reflected, in particular, in the increased size of the placenta. In addition, the fetuses respond in this period with an adaptive reaction of their own to stress, resulting in an increase in their rate of growth."

+Varia. Newton, G., Heimstra, N.: "Effects of early experience on the response to whole-body x-irradiation." *Can. J. Psychol.* **14**: 111-120 (1960). D84,835/60

Weanling rats which have been previously handled lose less weight following x-irradiation than do controls.

Trujillo, T. T., Spalding, J. F., Langham, W. H.: "A study of radiation-induced aging: response of irradiated and nonirradiated mice to cold stress." *Radiation Res.* **16**: 144-150 (1962). D24, 525/62

In mice, resistance to standard "cold stress" showed a linear decrease with age. The same reaction was obtained after x-irradiation. "The radiation-induced effect was considered similar to life shortening by natural aging."

Gauron, E. F., Rowley, V. N.: "Infantile shock traumatization and the mitigating effects of tranquilizing drugs." *J. Genet. Psychol.* **111**: 263-270 (1967). J22,350/67

Atherton, R. W., Ramm, G. M.: "General observations, erythrocyte counts and hemoglobin concentration in chick embryos subjected to centrifugal stress." *Aerosp. Med.* **40**: 389-391 (1969). J22,401/69

Norton, L., Nolan, P., Sales, J. E. L., Eise-

man, B.: "A swine stress ulcer model." *Ann. Surg.* **176**: 133-138 (1972). G93,135/72

Adult pigs are unusually resistant to the production of gastric ulcers by the stress of hemorrhage, whereas young piglets are particularly sensitive (19 refs.).

Upshall, D. G.: "Effects of o-chlorobenzylidene malononitrile (CS) and the stress of aerosol inhalation upon rat and rabbit embryonic development." *Toxicol. Appl. Pharmacol.* **24**: 45-59 (1973). J435/73

Meserve, L. A., Leathem, J. H.: "Neonatal hyperthyroidism and maturation of the rat hypothalamo-hypophyseal-adrenals axis." *Proc. Soc. Exp. Biol. Med.* **147**: 510-512 (1974). H97,672/74

In rats, thyroid feeding during pregnancy does not change the basal level of corticosterone in their pups but accelerates the maturation of the hypothalamo-hypophyseal-adrenal axis, as indicated by the response to ether stress or ACTH (30 refs.).

Thor, D. H., Ghiselli, W. B., Ward, T. B.: "Infantile handling and sex differences in shock-elicited aggressive responding of hooded rats." *Dev. Psychobiol.* **7**: 273-279 (1974). J12,750/74

Handling during infancy caused only minor changes in the aggressive response of male and female rats exposed to electric footshock in adulthood.

Mos, L., Vriend, J., Poley, W.: "Effects of light environment on emotionality and the endocrine system of inbred mice." *Physiol. Behav.* **12**: 981-989 (1974). J13,743/74

Mice of different strains were reared in either a dark or a light environment. "Strain and sex affected all organ weights, light rearing affected adrenal, spleen and ovary weight, and emotionality testing affected pituitary and adrenal weight. The results were interpreted that light rearing affects maturation of the hypothalamic-pituitary-adrenal axis and response to stress."

Sex (*Including the Sexual Cycle*)

Here, we shall discuss sex only as a stressor or conditioning agent; data on the effect of stress upon sexual activities, including the menstrual cycle, pregnancy, lactation and the structure of the sex organs, will be considered in the section Morphologic Changes.

Even in the first detailed paper on the G.A.S., it was pointed out that, following

exposure to stressors, female rats develop more marked thymicolumphatic involution than males, perhaps because their adrenals are larger to start with. However, there are many sex differences in responsiveness to various agents and certainly not all of them can be attributed to nonspecific mechanisms. Thus, it is well known that the sex hormones have a definite effect upon various specific detoxifying systems, including drug metabolism and clearance.

Sexual arousal is a typical stressor agent. In repeatedly bred rats, the incidence of arteriosclerosis and mild hypertension is increased, although it is not clear what part the different aspects of breeding (sexual intercourse, pregnancy, lactation) play in this response.

Under crowded urban conditions, men tend to become more competitive and aggressive, whereas women seem to assume a more lenient attitude toward each other. Women are increasingly entering occupations previously reserved for men, and their longevity appears to be decreasing gradually to the normal male level. Now they are more commonly subject to stress-induced diseases than has previously been the case, at least in Western societies.

Undoubtedly, the sexual cycle, especially its anomalies and premenstrual tension, can act as a stressor in females during the reproductive period of life.

In the Pacific salmon, during its spawning migration which lasts several months, the adrenals are considerably enlarged, and there is evidence of increased corticoid secretion as a consequence of this severely stressful activity.

When films that cause sexual arousal were viewed, catecholamine excretion was raised more markedly in male than in female students. There can be no doubt that many sex-dependent factors affect stress resistance but, despite the ample data published, it is still impossible to make any generalizations concerning the sex differences, because the subject is markedly complicated by the many specific elements, both somatic and psychosocial, that influence this phenomenon.

Sex (including the Sexual Cycle)

(See also our earlier stress monographs, p. xiii)

Selye, H.: "Studies on adaptation." *Endocrinology* 21: 169-188 (1937). 38,798/37

Experiments on rats showed that age and sex can noticeably influence resistance to stressors. "Old animals react more readily than young ones, possibly because much of their adaptation energy has already been used to meet the incidental demands of life. This probably explains also why resistance against almost any alarming stimulus is more difficult to obtain in fully adult rats, a fact which led to the use of animals 2 to 3 months of age in preference to older ones for the purposes of the present experimental series. Females show a more marked involution of the lymphatic organs after exposure to alarming stimuli than males. This may find its explanation in the fact that the adrenals are larger in the female rat than they are in the male."

G45,267/67

Williams, I.: "Some psychological stresses on women." *Med. J. Aust.* **2**: 97-100 (1968).

J10,827/68

Sociologic factors create a need for psychologic counselling among the "surprisingly small number of women who break down under stress of work and domesticity (very much in the field of marriage guidance), in dealing with worried parents and the girl who is difficult at school or in training for her career, and in all our contacts with education and personality training. I would put in the strongest possible plea to consider the whole aptitude of a girl before pushing her or allowing her to push herself into any occupation."

Levi, L.: "Sympatho-adrenomedullary activity, diuresis, and emotional reactions dur-

ing visual sexual stimulation in females and males." *Lab. Clin. Stress Res.* (Stockh.) Rep. No. 3: 1-33 (1968). G63,782/68

The viewing of films causing sexual arousal elicited more pronounced EP and NEP excretion in male than in female students. This difference paralleled self-rating scores in emotional reactions.

Gilbert, F. F., Bailey, E. D.: "Visual isolation and stress in female ranch mink particularly during the reproductive season." *Can. J. Zool.* **47**: 209-212 (1969).

J20,525/69

"Visual isolation is apparently more stressful to female mink during the anoestrous period but reduces stress during oestrus and pregnancy. The increased adrenal steroid output of control mink as part of the stress syndrome during the critical reproductive period might be responsible for increased *in utero* losses. But increased adrenocortical output associated with the stress of long term visual isolation might result in insufficient gonadal stimulation resulting in fewer pregnancies."

Hodges, W. F., Felling, J. P.: "Types of stressful situations and their relation to trait anxiety and sex." *J. Consult. Clin. Psychol.* **34**: 333-337 (1970). J20,483/70

Jégo, P., Lescoat, G., Beraud, G., Maniey, J.: "Etude des modalités de réponse du complexe hypothalamo-hypophysio-surrénalien à l'agression par l'éther chez le rat: cas d'une injection intrapéritonéale" (Study on the responsiveness of the hypothalamo-hypophysio-adrenal axis to stress by ether in the rat: effects of intraperitoneal injection). *C. R. Soc. Biol. (Paris)* **164**: 2117-2121 (1970).

H41,303/70

The increase in blood corticosterone produced in rats by ether is diminished by previous pentobarbital anesthesia. However, intraperitoneal injection of ether causes marked rises in blood corticosterone in pentobarbital-anesthetized females, but not in males.

Lescoat, G., Jégo, P., Beraud, G., Maniey, J.: "Influence du sexe sur les modalités de réponse de l'axe hypothalamo-hypophysio-surrénalien aux agressions émotionnelles et somatiques chez le rat" (Sex influences on the response of the hypothalamo-hypophysio-adrenal axis to emotional and systemic stress in the rat). *C. R. Soc. Biol. (Paris)* **164**: 2106-2113 (1970). H41,302/70

Halevy, S., Altura, B. M.: "Sex and genetics as factors influencing resistance to traumatic shock." *Fed. Proc.* **33**: 298 (1974). H84,061/74

Certain "strains of mice could be used as models to explore further the roles of sex and genetics in resistance to traumatic shock."

Wexler, B. C.: "Adrenocortical changes associated with methylandrostenediol-induced hypertension and isoproterenol-induced myocardial infarction in arteriosclerotic versus nonarteriosclerotic rats." *Lab. Invest.* **30**: 251-259 (1974). J12,177/74

Repeatedly bred rats had naturally-occurring arteriosclerosis and mild hyperten-

sion. If they were treated with isoproterenol, their mortality was high, serum triglycerides and cholesterol were greatly elevated and the repair of drug-induced cardiac necroses was impeded by the formation of aneurysms. It is concluded that "preexisting, chronic, severe hypertension plays a key role in the pathogenesis of left ventricular aneurysm formation during acute myocardial infarction and that severe hypertension combined with arteriosclerosis portends a poor prognosis toward survival" (42 refs.).

Eliot, R. S.: *Stress and The Heart*, Vol. 1, p. 415. Mount Kisco, N.Y.: Futura, 1974.

E10,556/74

Monograph containing many articles by numerous experts on the role of stress in the production of cardiovascular disease, with special reference to hypertension and myocardial infarction. There are chapters dealing with the role of occupation, homeostasis, environmental influences, sex, athletics, emotions and stress tests as well as the therapeutic value of various techniques for relaxation, including Transcendental Meditation, Yoga, Zen, sentic cycles, hypnosis and related practices.

Pregnancy and Lactation

Urinary corticoid excretion is increased during certain periods of gestation in women, and undoubtedly pregnancy, childbirth and lactation represent important sources of stress in females. Yet, curiously, in general, women with peptic ulcers tend to be free of symptoms during pregnancy.

Pregnancy, Lactation

(See also our earlier stress monographs, p. xiii)

Cope, C. L., Boysen, X., McCrae, S.: "Some observations on endogenous cortisone excretion in man." *Br. Med. J.* September 29, 1951, pp. 762-767. B64,531/51

Urinary corticoid excretion (assayed by eosinopenia in adrenalectomized mice) is increased in a variety of diseases (status asthmaticus, coronary infarct, bronchopneumonia, carcinoma of pancreas, pneumococcal meningitis, congestive cardiac failure, diabetic ketosis) as well as in late pregnancy.

Soiva, K., Grönroos, M., Aho, A. J., Rinne, U.: "Über die Einwirkung von 'Stress' auf die Geschlechtsorgane und -funktionen der

schwangeren und nicht-schwangeren Ratten" (On the effect of "stress" on the sexual organs and functions of the pregnant and non-pregnant rat). *Geburtshilfe Frauenheilkd.* **20**: 505-508 (1960). G97,218/60

"Auditory and visual stress of 2-4 weeks' duration produced a decrease or a complete cessation in the activity of the genital system of non-pregnant rats." However, gestation failed to protect against the usual consequences of stress.

tation in rats." *Neuroendocrinology* **12**: 179-191 (1973). H74,724/73

In rats, suckling itself induced ACTH discharge, and the elevated basal plasma corticosterone level during lactation was diminished by ether stress. "After dexamethasone treatment, the corticosterone output to exogenous ACTH was lower in the plasma and higher in the adrenal" of lactating than of non-lactating rats.

Machtey, I., Meer, A.: "In certain physiological stress conditions on the problem of hyperuricemia." *Adv. Exp. Med. Biol.* **41**: 419-421 (1974). J24,476/74

Blood levels of uric acid remained essentially constant during menstruation and ovulation but rose considerably during labor and following delivery. "It is therefore an attractive assumption, that the marked stress connected with labour is the possible cause of the hyperuricemia found in the reported cases."

Schlein, P. A., Zarrow, M. X., Denenberg, V. H.: "The role of prolactin in the depressed or 'buffered' adrenocorticosteroid response of the rat." *J. Endocrinol.* **62**: 93-99 (1974). H90,051/74

The diminished corticosterone secretion of lactating rats under stress is due to a blockade produced by an increased LTH level.

Hamburg, M., Mendoza, L. A., Rader, M., Lang, A., Silverstein, H., Hoffman, K.: "Malformations induced in offspring of crowded and parabiotically stressed mice." *Teratology* **10**: 31-37 (1974). J15,934/74

Malformations were induced in fetuses of mice kept under crowded conditions or parabiotically joined during pregnancy. "The abnormalities included amputation of peripheral limb structures, open neural folds, exencephaly, blisters, head, face, and tail malformation, and generalized growth retardation. The hypothesis that the teratogenic and other effects were consequences of prolonged prenatal stress induced by the experimental conditions is supported by the observation that both procedures led in a short time to significant increases in mean maternal adrenal weight."

Cohler, B. J., Grunebaum, H. U., Weiss, J. L., Gallant, D. H., Abernethy, V.: "Social relations, stress, and psychiatric hospitalization among mothers of young children." *Soc. Psychiatr.* **9**: 7-12 (1974). J15,145/74

Hospitalization for psychiatric disturbances of mothers of young children is associated with psychogenic stress; it "is believed to be related both to impairment in a woman's performance of her role as housewife and mother, as well as to life stress experienced prior to hospitalization."

GENETICS, RACE, CONSTITUTION

(See also Diseases of Adaptation in man—particularly in relation to urbanization, demographic factors, social and cultural stressors)

Undoubtedly, genetic factors are among the most important endogenous conditioning agents which predispose certain individuals, species and races to respond in a particular manner to identical stressors. Consequently, as we shall see, some species of animals genetically predisposed to hypertension, audiogenic seizures, aggressive behavior, or even stress as such, have furnished investigators with especially useful test objects for the study of various types of stress reactions.

pituitary principles." In: Greep, R. O. and Astwood, E. B., *Handbook of Physiology. Section 7. Endocrinology*, Vol. IV, Part 1, pp. 131-171. Washington, D.C.: American Physiological Society, 1974. E10,727/74

Review on vasopressin and oxytocin secretion during stress in various species (215 refs.).

Vertebrates

Man. In the many studies on the effect of racial and other genetic factors upon the stress resistance of people with different genetic backgrounds, it has been particularly difficult to distinguish the role of heredity as such from the associated differences in cultural, climatic socioeconomic and other demographic conditions which influence diverse populations. There is no doubt, however, that even in our Western civilization, certain individuals are genetically predisposed to respond very differently to the common stressors of pleasant and unpleasant events, interpersonal relationships in the family and at work, wars and other emergency situations, economic problems, disease and so on.

Extensive studies on primitive, rural or nomadic populations—as well as on Jews, the Irish, Mexicans, Negroes, Japanese, Eskimos, American Indians, and other races—have shown wide differences in their susceptibility to certain stressors, including the development of hypertension, peptic ulcers, mental illness, diabetes, ulcerative colitis and other diseases of adaptation. Among typical Caucasians, several investigators claim to have observed variations in stress resistance, depending upon physique and personality types.

Bat. In the bat, captivity during hibernation did not influence adrenal ascorbic acid content, but arousal of noncaptive hibernating bats caused a rise in the blood corticosterone level. ACTH and EP elicit similar effects, but these are definitely diminished during hibernation. *

The EM changes in the adrenals of bats have been carefully examined during hibernation. In this species, two types of medullary cells can be differentiated, one producing EP, the other NEP. The secretory activity of the cortex is diminished during hibernation and rises rapidly upon arousal.

Cat. Comparatively few investigators have performed studies on stress using the cat as an experimental animal. Yet it is noteworthy that in the cat the adenohypophysis receives no arterial blood and is supplied only by portal vessels descending from the stalk. Consequently, transection of the latter causes pituitary necrosis and renders the species unsuitable for studies on severance of the pituitary from the hypothalamus.

Unilateral adrenalectomy elicits ascorbic acid depletion in the contralateral gland of the cat, and this effect can be blocked by cortisol. Yet, compensatory hypertrophy of the adrenal is not as obvious here as in most other species.

Cattle. In cattle, various diseases are associated with histologic signs of adrenocortical hyperactivity, presumably as a consequence of their stressor action. "Heat

stress" adversely affects the spermatogenesis and fertility of bulls. It must be remembered, however, that heat has a known specific damaging influence on testicular tissue. In calves, aldosterone excretion is allegedly increased by shipping.

Donkey. Presumably because of a particularly efficient sweating and rehydration mechanism elicited by EP secretion, donkeys are extremely resistant to "desert heat stress." Interdermal injection of EP causes local sweating in the donkey and horse.

Gerbil. Certain genetically predisposed gerbils respond to stressors (electroshock, photic or auditory stimulation) with typical epileptoid seizures.

Goat. In goats, extensive investigations have confirmed that transection of the pituitary stalk (with prevention of anastomosis formation by a plate) causes infarction and/or atrophy of the adenohypophysis and infundibular process, but the intermediate lobe undergoes considerable hypertrophy. This finding may help in learning more about the hypothalamus-pituitary pathways, which play an important role in the mediation of stress responses.

Guinea Pig. In guinea pigs, prolonged exposure to noise or cold produces typical histologic changes in the adrenal cortex, which follow the three stages of the G.A.S. Pretreatment with ascorbic acid allegedly reverses the eosinophil response and virtually blocks the loss of ascorbic acid from the adrenals of guinea pigs exposed to cold.

In newborn guinea pigs, deafferentation of the hypothalamus impairs growth and gonadal function, but leaves thyroid and adrenal activity unaffected in males and only moderately diminishes it in females.

Hamster. Hamsters are also quite commonly used in experiments on stress. Allegedly, Syrian hamsters show little evidence of adrenal enlargement during exposure to cold, either during hibernation or at other times, yet the hamster adrenal is normally sensitive to other stressors.

No special seasonal variations in catecholamine excretion were noted in hamsters, although the elimination of these compounds is actually diminished during adaptation to cold. On the other hand, urinary glucocorticoid and aldosterone excretion is subject to definite seasonal fluctuations. At the time of awakening from hibernation, there appear signs of hyperactivity in both the cortex and medulla of the hamster adrenal.

Chinese hamsters unfamiliar with each other immediately start fighting when placed in the same cage. This results in glycosuria with a catecholamine and corticoid discharge characteristic of stress. It has been pointed out that such a response may help in our explorations of stress-induced diabetes.

Horse. In ponies, neither handling, repeated venipuncture, nor EP-induced hyperglycemia elicited eosinopenia, but injections of ACTH, insulin or histamine did bring about this response.

Adaptation to cold and muscular training increased thyroxine secretion in the horse, and exposure to various stressors caused singular pancreatic lesions whose pathogenesis has not yet been clarified.

Surgical trauma and induced hypoglycemia raise plasma cortisol levels, whereas exercise is much less effective in this respect. It is concluded that the mechanisms con-

trolling adrenocortical functions in the horse are similar to those in other mammals, although, curiously, here the plasma cortisol variations are not necessarily associated with corresponding changes in eosinophil count.

Monkey, Ape. As far as their hypothalamus-pituitary-adrenocortical and catecholaminergic responses are concerned, monkeys and apes appear to react to stressors essentially like human beings. This is true also of many other stress parameters. For example, in squirrel monkeys captured in Colombia, serum cholesterol rose significantly after transportation to North Carolina, presumably because of the stressor effect of translocation; this effect has also been demonstrated in man and many other species. Curiously, restraint has been claimed to decrease blood cholesterol in rhesus monkeys, at least under certain conditions. The major steroid produced during stress in monkeys and apes appears to be cortisol. In addition, capture, restraint and aversive conditioning also increase the plasma STH of the squirrel monkey.

In rhesus monkeys, electric stimulation of various hypothalamic areas results essentially in the same hormone reactions as in other species, including, presumably, man.

Mouse, Garden Doormouse. Certain strains of mice are particularly susceptible to audiogenic seizures, during which they exhibit typical manifestations of the G.A.S. such as eosinopenia, increased corticoid and catecholamine secretion. The brain levels of NEP and 5-HT are especially high in these seizure-susceptible strains. However, in the mouse—as in the rat—the genetically determined sensitivity to sound appears to be quite specific, and the manifestations of stress are secondary to the convulsive response. There is no definite evidence of hypersensitivity to other stressors.

In extremely seizure-susceptible mice, reserpine and MAO inhibitors diminish the lethality of convulsions. In conjunction with the observation that brain NEP is depleted during lethal seizures, it was assumed that NEP deprivation of nervous centers may be the cause of mortality. Yet, in mice rendered resistant to seizures by repeated exposure to sound, the brain NEP concentration also drops. Perhaps, lethality depends upon a particularly rapid catecholamine loss.

Allegedly, in mice, hypoglycemia and exposure to cold did not stimulate STH secretion, whereas fasting caused a slight depletion of the STH level in the pituitary and an increase in the plasma. Perhaps because of the high metabolic rate of this species, STH secretion is already near-maximal under basal conditions and hence cannot readily be raised further.

In hairless strains of mice, immobilization and exposure of the skin surface to intense sound vibrations can act as potent stressors, presumably because of impaired temperature regulation resulting from the absence of fur.

No definite difference in endurance was noted between wild and domestic mice swimming in cold water.

In mice with a "lethargic" mutant recessive gene, forced swimming causes especially pronounced manifestations of stress.

Pig. As judged by adrenal ascorbic acid determinations, chlorpromazine diminishes ACTH secretion in pigs exposed to high temperatures.

In baby pigs, cold or starvation causes typical G.A.S. changes with adrenal lipid loss, hypoglycemia and eosinopenia.

Stress may also elicit aggressive behavior, infarctoid cardiac necrosis and peptic ulcers in the stomach of pigs.

It has been possible to produce stress-susceptible and stress-resistant strains of pigs, by selective breeding.

Rabbit, Hare. Certain strains of wild rabbits react to frightening stimuli (for example, fear of a chasing dog) with a singular response designated by one group of investigators as "stress thyrotoxicosis." Here, thyroid hyperthyroidism and exophthalmus, due to increased TTH secretion, are associated with adrenocortical enlargement and are sometimes conducive to sudden death. The response can be prevented by hypophysectomy or methylthiouracil. There appears to be some ambiguity concerning the corticotrophic response, since in another publication the same investigators state that "the symptomatology and the cause of fear thyrotoxicosis can be classified in terms of the phases of the alarm reaction, resistance and exhaustion (Selye). Increased thyrotropic function causes inhibition of ACTH secretion." This latter finding might be explained by the "shift in hypophyseal hormone production," yet at other times both TTH and ACTH discharge may apparently be enhanced simultaneously.

In most strains of rabbits, stressors elicit only the usual response of the hypophysis-adrenocortical system. Both corticosterone and cortisol show a circadian rhythm with a peak during the day and a drop at the end of the night.

In captive hares, the presence of a hunting dog may elicit testicular atrophy as a result of fear. This finding agrees with the well-known tendency of stressors to cause gonadal involution.

Rat. Since the rat is the most common laboratory animal used in experiments on stress, there are ample data concerning strain differences in the nonspecific resistance of this species.

Comparative studies on wild and domesticated rats showed that the former have larger adrenals and a smaller thymicolympathic apparatus, since they are much more frequently exposed to stressors than are the sheltered laboratory variety. Also, in contrast to the domesticated type, wild rats cannot be indefinitely maintained on sodium chloride after adrenalectomy. Furthermore, the adrenals of wild Norway rats are less sensitive to intestinal trauma, hemorrhage, ether anesthesia, unilateral adrenalectomy, or even ACTH administration than are those of domesticated individuals of the same strain, as indicated by ascorbic acid depletion.

In the Brattleboro strain of rats, a hypothalamic diabetes insipidus tends to develop, which can be corrected by vasopressin. In these animals, stress caused by ether anesthesia or bleeding still raised plasma corticosterone, but to a significantly lesser extent than in normal controls. The CRF activity in the ME and the ACTH concentration in the pituitary were essentially the same in both strains. Hence, it was concluded that, although vasopressin is not identical with CRF, it may play a minor role in the adrenocortical response to stress.

In vitro observations suggest that, in the Brattleboro rat, the adrenal glands themselves are relatively insensitive to ACTH. It has been postulated that perhaps the absence of vasopressin in the internal milieu during early life may permanently influence adrenal sensitivity.

Another strain of rats is particularly susceptible to audiogenic seizures; they re-

spond very strongly to what has been called "auditory stress," which elicits pronounced adrenocortical hypertrophy and thymus involution.

Yet another strain of rats is congenitally predisposed to the spontaneous development of hypertension, and this tendency is aggravated by stress.

Sheep. A good deal of work has been done on sheep to verify the localization of the hypothalamic centers responsible for different types of adenohypophyseal activity. According to some investigators, transection of the stalk sometimes prevents the ACTH-induced corticoid discharge (presumably when no vascular anastomoses develop). Others, who inserted a plate between the cut ends of the stalk, found that most of the pituitary actually undergoes infarction in this species.

Various stressors, such as cold, EP and NEP, elicit the usual biochemical changes in lambs, that is, an increase in FFA, lactic acid and glucose with a decrease in muscle glycogen and body temperature. In accordance with observations on other species, repeated exposure to stressors induces resistance.

Tupaia. The tree shrew (*Tupaia belangeri*) lends itself particularly well to certain experiments on stress, because the hairs on the tail normally lie flat, but they become erect and bushy upon the slightest stimulation, thereby offering a readily visible indicator of increased sympathetic activity. This response is especially evident during sexual arousal of *Tupaias* or aggressive confrontation of two males. The phenomenon has been regarded as part of the G.A.S.

Male *Tupaias*, after being defeated by a trained fighter, become terrified upon seeing him, even if protected by a separating wire mesh. If the fight is repeated every one or two days, the defeated *Tupaia* dies in less than three weeks due to "psychosocial stress," even without suffering any mortal wounds. This response is characterized by adrenal enlargement and an increased ascorbic acid concentration, in contrast to a decrease in most other species. The blood glucocorticoids rise, and at the same time there is a loss of liver glycogen and body weight associated with an eventually fatal uremia due to kidney damage.

Although these experiments were all conducted under essentially identical conditions by the same investigator, they suggest that the *Tupaia* is particularly sensitive to psychogenic stress and in some respects responds to it in an unusual manner.

Various Other Mammals. Among other mammals, special attention has been given to the *hedgehog*, in which the changes induced by hibernation were similar to those of the G.A.S. However, presumably this is true only during arousal, since in deep hibernation the function of the adrenals is greatly diminished, although the mitochondria retain their EM characteristics.

Additional data on stress responses in the *beaver*, *deer*, *dolphin*, *ferret*, *giraffe*, *marsupials* (*kangaroo*, *wallabies*), *mink*, *mongoose*, *opossum*, *squirrel*, *vole*, *woodchuck* (*Marmota monax*) and others will be found in the abstract section in alphabetic order.

It appears that, in the lowest order of mammals (*Monotremata*), adrenal function is not very well developed. Still, their resistance to cold is diminished by adrenalectomy, and adrenal hypertrophy in *echidnas* shows the importance of these glands for resistance to stressors, such as fasting and cold.

Birds. Many stress studies have been performed on birds. In laying *chickens*, crowding causes adrenal hypertrophy and diminishes egg production, presumably as a consequence of stress.

Young chicks imprinted to surrogate mothers allegedly showed increased resistance to the stressor effect of a door bell, both in the presence and in the absence of their substitute mothers.

By moving cockerels into cages with other birds, it is possible to produce typical stress phenomena, such as adrenal hypertrophy, a loss of cholesterol, involution of the bursa, changes in blood count, decreased resistance to infection and even a rise of plasma corticosterone.

In chick embryos, breaking one shank (after opening the shell) elevates plasma corticosterone concentrations to some extent. However, the pituitary becomes important after two weeks of incubation in maintaining both the resting level of the hormone and the stress response. At this early age, the hypothalamus does not appear to control resting blood levels of corticosterone, although it is essential for the stress response. The initial autonomy of the adrenal cortex is demonstrated by persistent plasma corticosterone concentrations after decapitation of the embryo.

In the *pigeon*—as in most birds—the cortical and medullary cells of the adrenals are intermixed. Hypophysectomy causes only a slight decrease in adrenal weight, due mainly to atrophy of the interrenal (cortical) cells near the center of the gland, but various stressors (formaldehyde, insulin) induce hypertrophy of both interrenal and chromaffin cells, even in hypophysectomized pigeons. Allegedly, very large lesions in the ME and ventral hypothalamus produced adrenal hypertrophy rather than atrophy, even after total hypophysectomy, and did not prevent the response to formaldehyde. It was concluded from this that “the interrenal tissue of the pigeon responds to a humoral stimulus, not of hypophyseal origin in the absence of the hypophyseal hypothalamic system.” However, these findings do not agree with some later observations.

By means of localized hypothalamic lesions in pigeons, a well-defined adrenocorticotropic area could be demonstrated in the posterior medial and lateral hypothalamic regions whose destruction resulted in a fall of plasma corticosterone, similar to that obtained by adenohypophysectomy. Lesions in this area also suppressed the adrenocortical response to stressors. It remains to be seen whether the residual adrenocortical response of the hypophysectomized pigeon is due to partial autonomy of the gland or to some extrahypophyseal control system. In any event, the fact that destruction of the hypothalamic regulating center abolishes corticotrophic activity shows that even in this species the function of the adrenal cortex is not completely autonomous, as was previously suggested.

Deafferentation of the hypothalamus suppressed the circadian variations of plasma corticosterone in pigeons, but only diminished the response to ether stress.

Insulin and metyrapone induce hypertrophy and hyperplasia of the ACTH-producing “epsilon cells” in the adenohypophysis of the pigeon, with EM manifestations of hyperactivity and an increase in the ACTH content of the gland. Presumably, the epsilon cells of birds are the source of ACTH.

Stress reactions have also been studied in the *turkey*, *duck*, *black-headed gull*, *quail*, *parakeet* and *myna*. Comparative investigations on several avian species have shown that dexamethasone causes atrophy of the interrenal gland without any clearcut evidence of zonal differences.

According to a review of the literature, in several species of birds the hypothalamus can produce an extrahypophyseal ACTH-like polypeptide. In any event, the bird adrenal responds directly to ACTH by hypertrophy and increased corticoid secretion.

Reptiles. The adrenals of *lizards* consist of a dorsal medullary and a ventral interrenal (cortical) portion. In the Yucca night lizard, hypophysectomy, cortisone and DOC cause involution of the interrenal cells with lipid depletion. ACTH, which induces hypertrophy of this tissue, also depletes it of lipids. Similar changes indicative of interrenal hyperactivity are produced by the stress of starvation.

In the lizard *Anolis carolinensis*, a neuro-intermediate lobe grafted below the skin elicits a local small dark patch, owing to MTH discharge, and exposure to stressors results in a rapid release of MTH.

Turtles are especially adaptable to low or high oxygen tension, ultraviolet radiation and cold. This property makes them particularly suitable for certain types of stress research. Allegedly, they can long survive under anaerobic conditions, or at temperatures as high as 41°C. In this species, weight loss appears to be a better index of thermal stress than pulse rate.

Other reptiles used for stress research are *snakes*, *caimans* and *iguanas*.

Amphibians. The morphology and function of the pituitary-adrenal system have been carefully studied in frogs and toads.

In the *frog*, brief immobilization causes hyperactivity of the interrenal tissue, as indicated by increased plasma corticosterone levels and excess synthesis of corticoids in adrenal homogenates.

In the *toad*, the hypothalamus consists of a pars basalis, lamina terminalis and lobus infundibularis. The latter is attached to the hypophysis, and if lesioned, the gland becomes largely atrophic, with increased absorption of MTH (manifested by darkening of the animal) and other hormonal derangements. Under ordinary conditions, the toad responds to various stressors (cold, dehydration) and to ACTH with depletion of adrenocortical lipids, but in hibernation, allegedly, only dehydration is effective in this respect.

In the *newt*, hemorrhage caused neutrophilia followed by lymphopenia and eosinopenia. Since mere handling of the animals induced similar changes, these were ascribed to stress.

Fish. There exists considerable literature on the effect of stressors upon various types of fish, in some of which the chromaffin (medullary) and interrenal (cortical) tissues are intermixed, while in others they are completely separate. It was the latter type of arrangement that first permitted the demonstration that the interrenal gland is indispensable for the maintenance of life, since its selective removal caused muscular weakness and hyperpigmentation (similar to the manifestations of Addison's disease) which could be cured by interrenal extracts.

In the *goldfish*, in which the two cell types are intermixed, ACTH failed to alter the granulation of interrenal cells, but produced condensation of their cytoplasm as well as alterations in chromaffin cells. Similar changes were evoked by exposure to extremes of temperature. Evidence of increased corticoid and catecholamine secretion as well as other manifestations typical of stress have also been observed in numerous species of fish.

According to one group of investigators, the alarm reaction in fish is believed to be produced by a special substance, "pheromone," secreted by cells of the epidermis. A crude preparation of "alarm pheromone," dropped into an aquarium, causes fright and alarm behavior, withdrawal, and even enhancement of avoidance conditioning in fish. However, it is not quite clear whether this substance and the changes it produces are actually related to the alarm reaction, as described in mammals.

In goldfish, the blood cortisol levels show a clearcut circadian rhythm and a particularly pronounced rise following exposure to diverse stressors.

In various species of fish, the heart rate is also accelerated by hypoxia.

The stressors most often investigated in fish are changes in salinity, temperature variations, capture and restraint, muscular fatigue, hypoxia, hemorrhage and trauma. The most common indicators of stress are: increased catecholamine and corticoid secretion, characteristic changes in blood count, loss of body weight, variations in blood sugar, depletion of liver glycogen, high serum lactate and glucose as well as elevation of hepatic tyrosine aminotransferases.

Among *teleosts*, the prolonged swimming, without food intake, from Europe to the spawning grounds three thousand miles away represents a particularly potent stressor. In the migrating *Pacific salmon*, there is considerable hyperactivity of the interrenal body, and blood corticoid concentrations are increased. At the same time, the plasma EP level also rises.

In general, it may be said that the hypothalamus-pituitary-adrenocortical and catecholamine responses to stressors are essentially the same in fish as in mammals, whether their chromaffin and cortical tissue is separate or intermixed. However, it has not as yet been resolved with certainty that fish are equally, or less, dependent upon higher centers for their adrenal activity and for their stress responses in general.

Salem, S. N., Shubair, K. S.: "Non-specific ulcerative colitis in Bedouin Arabs." *Lancet* March 4, 1967, pp. 473-475.

F77,588/67

In Bedouins and other nomadic Arabs, ulcerative colitis has been noted after settlement in Kuwait city. Presumably, "the sudden shift from a simple life to a complicated one predisposes these people to the disease."

Jenkins, C. D., Rosenman, R. H., Friedman, M.: "Development of an objective psychological test for the determination of the coronary-prone behavior pattern in employed men." *J. Chron. Dis.* **20**: 371-379 (1967).

J5,580/67

"Coronary-prone behavior pattern, called Type A, is characterized primarily by excessive drive, aggressiveness, ambition, involvement in competitive activities, frequent vocational deadlines, pressure for vocational productivity, an enhanced sense of time urgency and restless motor mannerisms and staccato style of verbal response. The converse, low coronary-risk behavior pattern, called Type B, is characterized by the relative absence of this interplay of psychological traits and situational pressures. The Type B subject is relaxed and more easy going, seldom becomes impatient and takes more time to enjoy avocational pursuits. He is not easily irritated and works steadily, but without a feeling of being driven by a lack of time. He is not preoccupied with social achievement, and is less competitive in his occupational and avocational pursuits. He moves and speaks in a slower and more smoothly modulated style." Sir William Osler was one of the first to describe a typical behavior pattern in coronary-prone patients. The types presently outlined can be further divided into subtypes (23 refs.).

Opton, E. M. Jr., Lazarus, R. S.: "Personality determinants of psychophysiological response to stress: a theoretical analysis and an experiment." *J. Pers. Soc. Psychol.* **6**: 291-303 (1967).

J8,942/67

An effort was made to find connections between personality and individual differences in response to stressors. "A 795-item personality inventory revealed 131 discriminating items in an ipsative (intraindividual) design. Ss who responded relatively more strongly to a threatening motion-picture film than to threat of electric shock described themselves as lacking in impulse expression, socially inhibited, introverted, submissive, suggestible or obedient, insecure, passive, anxious, and not caring about friends. Ss who responded more strongly to threat of shock than to the movie attributed the opposite qualities to themselves. Normative (interindividual) analyses (high response to film compared to low response to film, high response to shock compared to low response to shock) found no more discriminating personality items than would be expected by

chance." The questionnaire included the five hundred items of the BPI, parts of the MMPI, the IES, the APQ, the SEI and other miscellanea.

Meloni, C., Torre, E.: "Stress, reazione neurovegetativa e tipo di personalità in soggetti normali e cardiopatici ischemici" (Stress, neuroautonomic reaction and type of personality in normal and ischemic cardiopathic subjects). *G. Ig. Med. Prev.* **9**: 3-20 (1968). J23,136/68

Bridges, P. K., Jones, M. T.: "Relationship of personality and physique to plasma cortisol levels in response to anxiety." *J. Neurol. Neurosurg. Psychiatry* **31**: 57-60 (1968). G56,652/68

During academic examinations, the plasma level of cortisol in medical students became considerably elevated as a consequence of anxiety. The degree of response was correlated with both the physical and the mental constitution of the candidates. "It is suggested that there is an intrinsic sensitivity in anxiety response to psychological stress that has an important association with physique."

Vallee, F. G.: "Stresses of change and mental health among the Canadian Eskimos." *Arch. Environ. Health* **17**: 565-570 (1968). G61,518/68

Study of the role of psychogenic stressors, as distinct from the stressor influence of the Arctic environment, in the genesis of mental disease among Canadian Eskimos. Special emphasis is placed upon the distinction between communal and personal stressors—the tendency among Eskimos to blame certain individuals or themselves for epidemics, starvation, drowning or getting lost—which are characteristic anxiety-producing situations among this population (12 refs.). [Somatic indicators of stress are not examined (H.S.).]

Morris, J. N., Gardner, M. J.: "Epidemiology of ischaemic heart disease." *Am. J. Med.* **46**: 674-683 (1969). G67,204/69

Extensive review on the social and medical implications of ischemic heart disease, which is particularly common among men "showing strong drive, competitiveness, time urgency and preoccupation with deadlines, and the frustrations attendant on these" (Type A). This is especially true in early middle age and results in particularly fatal disease. The incidence is twice that among Type B patients, who do not exhibit such personality traits.

Strydom, N. B., Williams, C. G.: "Effect

of physical conditioning on state of heat acclimatization of Bantu laborers." *J. Appl. Physiol.* **27**: 262-265 (1969) (15 refs.).

J14,803/69

Back, K. W., Wilson, S. R., Bogdonoff, M. D., Troyer, W. G.: "Racial environment, cohesion, conformity and stress." *J. Psychosom. Res.* **13**: 27-36 (1969). J22,201/69

Comparative studies on stress responses—especially the elevations of plasma FFA—in various groups, particularly blacks and whites.

Hoffman, H. E.: "Use of avoidance and vigilance by repressors and sensitizers." *J. Consult. Clin. Psychol.* **34**: 91-96 (1970).

J21,922/70

Re-evaluation of the concept according to which "repressors" and "sensitizers" (distinguished on the basis of a questionnaire) will respond differently to psychogenic stress situations. The sensitizer tends to confront threatening stimuli by intellectualization and isolation; the repressor by avoidance of the stressor.

Bailit, H. L., Workman, P. L., Niswander, J. D., MacLean, C. J.: "Dental assymmetry as an indicator of genetic and environmental conditions in human populations." *Hum. Biol.* **42**: 626-638 (1970). J20,565/70

Dental assymmetry may occur in various human populations as a consequence of genetic or environmental stress factors. "Genetic stress may result from inbreeding due to the finite size of the population or to a mating pattern involving consanguinity. This can lead to a reduction in population fitness because of the exposure of deleterious recessive genes in a homozygous state or, more importantly, because of a breakdown in the coadaptation of the genetic system. Indications of inbreeding stress are provided by estimates of the inbreeding coefficient, the effective population size, the amount of gene flow into the population, or by a comparison of the genetic variance of different quantitative characters with that observed in large random mating populations. Another genetic stress may result from a drastic diminution in population size, leaving too little genetic variation to adapt to a changing or extremely heterogeneous environment."

Dohrenwend, B. S., Dohrenwend, B. P.: "Class and race as status-related sources of stress." In: Levine, S. and Scotch, N. A., *Social Stress*, pp. 111-140. Chicago: Aldine, 1970.

B44,378/70

Bridges, P. K., Jones, M. T., Leak, D.: "A taxonomic study of physiological responses to a psychological stress." *J. Neurol. Neurosurg. Psychiatry* **33**: 180-187 (1970).

J11,245/70

In students, taxonomic studies were performed to establish the relationship between the stressor effect of examinations (plasma cortisol, catecholamine excretion, blood pressure and so on) and constitutional factors (body build, personality types).

Harburg, E., Schull, W. J., Erfurt, J. C., Schork, M. A.: "A family set method for estimating heredity and stress. I. A pilot survey of blood pressure among Negroes in high and low stress areas, Detroit, 1966-1967." *J. Chron. Dis.* **23**: 69-81 (1970).

G78,153/70

American blacks of both sexes have higher blood pressure and mortality from heart disease and strokes than do corresponding whites. A pilot study of blacks in low- and high-stress areas of Detroit suggested that "blood pressure levels were significantly correlated with different patterns of life stress for the essentially working class persons in the high stress area, and for the middle class persons in the low stress area. Briefly, working class persons in the high stress area with higher blood pressure levels (adjusted for sex, age and weight) reported greater economic frustration and more satisfaction (*sic*) with their marital life and their neighborhood than did their normotensive counterparts in the same tract. In contrast, middle class persons with higher blood pressure levels had higher occupational achievements and aspired to even more than did their normotensive neighbors."

Mendeloff, A. I., Monk, M., Siegel, C. I., Lilienfeld, A.: "Illness experience and life stresses in patients with irritable colon and with ulcerative colitis. An epidemiologic study of ulcerative colitis and regional enteritis in Baltimore, 1960-1964." *N. Engl. J. Med.* **282**: 14-17 (1970). H20,041/70

In the Baltimore area, "subjects with irritable colon had consistently higher scores for various social-cultural factors thought to represent life stresses than either the patients with ulcerative colitis or the general population. The group with ulcerative colitis resembled the general population in this respect, except for being significantly more Jewish." Specific stressor events preceding the outbreak of the disease could not be established, and hence these studies "fail to support the

thesis that ulcerative colitis is a paradigm of psychosomatic illness."

Matsumoto, Y. S.: "Social stress and coronary heart disease in Japan." *Milbank Mem. Fed. Q.* **48**: 9-36 (1970). G73,150/70

In Japan, the incidence of arteriosclerotic CHD is extremely low as compared to its incidence among white North Americans. "Although the diet factor remains dominant in current thinking, the stress hypothesis merits the most intensive probing as alternate or associated explanations of observed relations and differentiations" (87 refs.).

Beals, K. L.: "Head form and climatic stress." *Am. J. Phys. Anthropol.* **37**: 85-92 (1972). J20,343/72

"Based on a sample of 339 populations, the magnitude of the index is statistically different between zones of predominantly dry heat, wet heat, wet cold and dry cold. There is an inverse relationship between the mean cephalic index and temperature. It is argued that the occupation of cold climates is one of the circumstances increasing the frequency of brachycephaly through time," and that a relationship exists between climatic stress and head form.

Willett, E. A., Heilbronn, M.: "Repression-sensitization and discrepancy between self-report and official report of illness." *J. Psychol.* **81**: 161-166 (1972). J19,862/72

"The Repression-Sensitization (R-S) scale has been used to differentiate between two major defensive styles. Studies relating the R-S scale to measures of adjustment suggest that repressors are better adjusted than sensitizers."

Baldwin, B. A.: "Autonomic stress resolution in repressors and sensitizers following microcounseling." *Psychol. Rep.* **31**: 743-749 (1972). J19,724/72

Repressors tend to use avoidance mechanisms, such as withdrawal, denial, and rationalization in response to stress, whereas sensitizers, under the same conditions, typically overinterpret threat, and utilize approach mechanisms, such as obsessive rumination and intellectualization. Microcounseling based on this knowledge helps to resolve psychogenic stress.

Pagano, D. F.: "Effects of task familiarity on stress responses of repressors and sensitizers." *J. Consult. Clin. Psychol.* **40**: 22-26 (1973). J20,151/73

Comparison of the manner in which psy-

chogenic stressors affect repressors (characterized by the use of avoidance-denial techniques) and sensitizers (who use intellectual techniques of coping).

Bridges, P. K., Jones, M. T.: "Relationships between some psychological assessments, body-build, and physiological stress responses." *J. Neurol. Neurosurg. Psychiatry* **36**: 839-845 (1973). J7,429/73

During oral academic examination, constitutional factors greatly influenced the stress reaction. "Students of primarily linear physique had significantly higher plasma corticosteroid values than the predominantly muscular subjects at the time of the examination, as found previously. They also had significantly higher analogue measures of the degree of anxiety experienced at the examination (assessed both by the subject and by an observer.)"

Holmes, T. H., Masuda, M.: "Life change and illness susceptibility." In: Scott, J. P. and Seney, E., *Separation and Depression*, pp. 161-186. Washington, D.C.: Am. Assoc. Advancement Sci., 1973. J10,480/73

Among white and black Americans, Mexicans, Japanese, and various European ethnic groups, application of the SRRS revealed a "remarkable consensus about the common life events obtained when Americans, whose culture is embedded in the democratic Western ethic of internalized Christian moral values, are compared with Japanese, whose Eastern culture is embedded in a particularistic, hierarchical system emphasizing family-oriented, externally sanctioned rules of ethical conduct." On the other hand, it also showed certain cross-cultural quantitative and qualitative differences which are described in detail.

Harburg, E., Erfurt, J. C., Chape, C., Hauenstein, L. S., Schull, W. J., Schork, M. A., "Socioecological stressor areas and Black-White blood pressure: Detroit." *J. Chron. Dis.* **26**: 595-611 (1973). J8,243/73

Comparative studies in high- and low-stress areas of Detroit revealed that social and economic stress definitely predisposes to increased blood pressure, especially in blacks.

Harburg, E., Erfurt, J. C., Hauenstein, L. S., Chape, C., Schull, W. J., Schork, M. A.: "Socio-ecological stress, suppressed hostility, skin color, and Black-White male blood pressure: Detroit." *Psychosom. Med.* **35**: 276-296 (1973). J10,462/73

Comparative statistical studies on "socio-ecological stressor conditions" in various predominantly black or white areas of Detroit. Blood pressure levels were highest among male blacks in high-stress areas (47 refs.). [Characteristic G.A.S. manifestations were not examined (H.S.).]

Lumsden, D. P.: "Towards a systems model of stress: feedback from an anthropological study of the impact of Ghana's Volta River Project." In: Sarason, I. and Spielberger, C., *Dimensions of Anxiety and Stress—NATO Conference*, p. 40. House Publication, 1974. J15,030/74

An attempt to present a model of stress as an open system, based mainly on anthropologic studies of Ghana's Volta river project (125 refs.).

Win-May, M., Thin-Thin-Hlaing, Mya-Tu, M.: "Adrenocortical function in the Burmese." *Trop. Geogr. Med.* **26**: 126-132 (1974). J15,103/74

Adrenocortical function in the Burmese is essentially the same as in Europeans and Nigerians, both at rest and after treatment with ACTH or stressors.

Friedman, M., Byers, S. O., Diamant, J., Rosenman, R. H.: "Plasma catecholamine response of coronary-prone subjects (type-A) to a specific challenge." *Metabolism* **24**: 205-210 (1975). H98,918/75

The authors concisely summarize characteristics of CHD-prone (Type-A) and CHD-resistant (Type-B) persons as follows: "Type-A behavior pattern is an action-emotion complex shown by persons in chronic excessive struggle to achieve an unlimited number of things in the shortest possible time, perhaps against obstruction by other things or persons. The type-A individual does not despair of losing the struggle but confidently grapples with an endless succession of challenges. Type-A persons attempt to think, perform, communicate, and in general live more rapidly than do their peers.... Type-B subjects are the converse of type-A subjects. They tend to be introspective, less hostile or aggressive, and less concerned with time. Type-B subjects are concerned with quality rather than quantity of achievement; they pause to enjoy a goal attained rather than immediately setting out in pursuit of the next goal."

Bat. Krutzsch, P. H., Hess, M.: "Studies on the ascorbic acid content of the adrenal of

the bat (*Myotis lucifugus*)."
Endocrinology **69**: 664-666 (1961). D10,630/61

In the bat, captivity *per se* did not influence the vitamin C content of the adrenals during hibernation. "The most marked depletion of the adrenal vitamin occurred in the non-captive hibernating bats stressed by arousal, a finding well correlated with the blood corticosterone content reported for the hamster, another hibernating species, after similar treatment." Comparable though less pronounced effects were obtained with ACTH in hibernating animals, and with EP in active animals. Thus the bat responds to stress essentially as do most other species, at least with regard to the parameters examined.

Romita, G., Montesano, R.: "Aspetti istochimici ed ultrastrutturali delle ghiandole surrenali di Chiroterri durante l'ibernazione, il risveglio ed il periodo estivo" (Histochemical and ultrastructural aspects of adrenal glands in Chiroptera during hibernation, awakening and summer period). *Ateneo Parmense [Acta Biomed.]* **43**: 211-235 (1972). J1,213/72

Detailed description of the histochemical and EM changes in the adrenals of bats, especially with regard to the effect of hibernation. In the adrenal medulla, two types of cells have been differentiated, one synthesizing EP and the other NEP. "During the winter lethargy a depressed secretory activity has been noticed in the cells of the glomerulosa and moreover a remarkable secretion in the cells of both fasciculata and reticularis. Such activity increased after the awakening and became normal during the summer, demonstrating a tendency to store lipid droplets" (57 refs.).

Beaver. Smollich, A.: "Der Einfluss der DCA- und ACTH-Behandlung auf die Kerngrösse der Nebennierenrinde des Sumpfbibers" (The influence of DCA and ACTH treatment on nucleus size of the adrenal cortex in beavers). *Z. Mikrosk. Anat. Forsch.* **70**: 315-329 (1963). G2,544/63

In one beaver (*Myocastor coypus*), exposure to cold caused complete loss of lipids and doubly refractory substances, with other histologic changes which were ascribed to stress.

Cat. Merényi, D.: "Angioarchitektur der Katzenhypophyse. Morphologische Grundlagen zur experimentellen Forschung über das hypophyseo-diencephale System" (Angio-

architecture of the hypophysis in cats. Morphologic baseline for experimental investigations of the hypophyseal-diencephalic system). *Virchows Arch. [Pathol. Anat.]* **315**: 534-547 (1948). B27,100/48

Ink preparation injections indicate that in the cat the anterior lobe receives no arterial blood, and is supplied only by the portal vessels descending from the pars tuberalis and the stalk. Consequently, transection of the stalk causes pituitary necrosis; hence this species is unsuitable for studies concerning results of severing the pituitary from the hypothalamus.

Schwartz, N. B., Kling, A.: "Stress-induced adrenal ascorbic acid depletion in the cat." *Endocrinology* **66**: 308-310 (1960).

C80,679/60

In cats, unilateral adrenalectomy causes depletion of the ascorbic acid content of the remaining adrenal. This response can be blocked by cortisol, the blockade in turn being overcome by ACTH injection. Compensatory hypertrophy after unilateral adrenalectomy is not as obvious in the cat as in other species.

Cattle. Sybesma, W.: "Veranderingen in de bijnierschors van het zieke rund" (Changes in the adrenal cortex of the diseased dairy cow). *T. Diergeneesk.* **86**: 1129-1147 (1961) (Dutch). D42,897/61

Cattle exhibit an increase in the size of the adrenal cortex associated with histologic signs of hyperactivity and loss of vitamin C under the influence of a variety of diseases, particularly grass-tetany.

Shaw, K. E., Nichols, R. E.: "Plasma 17-hydroxycorticosteroids in calves—the effects of shipping." *Am. J. Vet. Res.* **25**: 252-254 (1964).

J24,154/64

Skinner, J. D., Louw, G. N.: "Heat stress and spermatogenesis in *Bos indicus* and *Bos taurus* cattle." *J. Appl. Physiol.* **21**: 1784-1790 (1966). G42,859/66

Even short-term exposure of bulls to "heat stress" can adversely affect spermatogenesis and fertility. [Since heat is known to have a specific damaging effect upon the testes, it remains to be shown that this is a nonspecific or stress action (H.S.).]

Rocco, A., Aguggini, G.: "Eliminazione urinaria degli 11-idrossi-corticosteroidi totali, dell'aldosterone e del testosterone nel vitello" (Urinary excretion of total 11-hydroxycorticosteroids, aldosterone and testosterone in

calves). *Boll. Soc. Ital. Biol. Sper.* **47**: 485-487 (1971). G88,973/71

In calves, aldosterone excretion is increased by the stress of travel. [The results do not lend themselves to statistical evaluation (H.S.).]

Wagnon, K. A., Rollins, W. C., Cupps, P. T., Carroll, F. D.: "Effects of stress factors on the estrous cycles of beef heifers." *J. Anim. Sci.* **34**: 1003-1010 (1972).

J20,504/72

Christison, G. I., Johnson, H. D.: "Cortisol turnover in heat-stressed cows." *J. Anim. Sci.* **35**: 1005-1010 (1972). J19,902/72

Wegner, T. N., Ray, D. E., Lox, C. D., Stott, G. H.: "Effect of stress on serum zinc and plasma corticoids in dairy cattle." *J. Dairy Sci.* **56**: 748-752 (1973).

J19,913/73

In cattle, various stressors produced inconsistent changes in serum zinc, which were not clearly related to the plasma corticoid levels.

Paape, M. J., Schultze, W. D., Miller, R. H., Smith, J. W.: "Thermal stress and circulating erythrocytes, leucocytes, and milk somatic cells." *J. Dairy Sci.* **56**: 84-91 (1973) (26 refs.). J19,911/73

Hartmann, H., Meyer, H., Steinbach, G., Deschner, F., Kreutzer, B.: "Allgemeines Adaptationssyndrom (Selye) beim Kalb. I. Mitteilung: Normalverhalten der Blutbildwerte sowie des Glukose- und 11-OHKS-Blutspiegels" (The general adaptation syndrome in calves. I. Normal behavior of the blood picture and the content of glucose and 11-hydroxycorticosteroids). *Arch. Exp. Vet. Med.* **27**: 811-823 (1973). J23,891/73

Deer. Tyler, C.: "The effect of prolonged emotional disturbance on the vasopressor and oxytocic activities contained in the posterior pituitary glands of fallow deer." *Arch. Int. Pharmacodyn. Ther.* **131**: 301-308 (1961).

D86,848/61

In deer harried before being shot, the ratio of vasopressin to oxytocin progressively increased in the posterior pituitary, probably owing to a fall in oxytocin.

Dog. Thorne, F. C.: "Differing reactions of friendly and fear-biting dogs to severe stress." *J. Clin. Psychol.* **24**: 181-184 (1968). J23,708/68

Corson, S. A.: "Physiologic responses to avoidable and unavoidable psychologic stress

in relation to genetic differences." *Ann. N.Y. Acad. Sci.* **164**: 526-534 (1969).

J21,196/70

"Genuine" epileptic seizures are produced in isolated dogs of a special breed by exposure to the stressor effect of strong noise. These animals show a clear familial predisposition to epileptic seizures.

Courtney, G. A., Marotta, S. F.: "Adrenocortical steroids during acute exposure to environmental stresses: I. Disappearance of infused cortisol." *Aerosp. Med.* **43**: 46-51 (1972).

J20,019/72

Courtney, G. A., Marotta, S. F.: "II. Uptake and release of infused cortisol by the hind limb of dogs." *Aerosp. Med.* **43**: 52-55 (1972).

J20,018/72

In dogs, the disappearance rate of infused cortisol was not very consistently affected by a variety of stressors.

Dobsinska, E., Lehky, F.: "Effect of transportation as a stress factor on the blood picture of the German shepherd-dog." *Vet. Med. (Praha)* **18**: 499-506 (1973).

J24,388/73

Zike, W. L., Safae-Shirazi, S., Denbesten, L.: "The role of cholestyramine in the prevention of stress ulcers." *J. Surg. Res.* **17**: 315-319 (1974).

J19,651/74

In dogs, stress ulcers produced by hemorrhagic shock plus intragastric instillation of hydrochloric acid and bile salts can be prevented by cholestyramine.

Carmichael, S. W.: "Fluorescence microscopy of the adrenal medulla of the newborn puppy after asphyxia and hypothermia." *Acta Anat. (Basel)* **87**: 131-140 (1974).

J12,617/74

"Hypothermia reduces the release of catecholamines from the adrenal medulla to such a degree that there is little or no depletion of catecholamines during 32 min of total anoxia."

Dolphin. Maier, R. A.: "Effects of stress upon social distance in dolphins." *Percept. Mot. Skills* **27**: 862 (1968).

J22,143/68

"The reduced social distance, similar to the tight schooling observed in dolphins in the open ocean, is apparently a general reac-

tion to stress. This reaction may function to increase protection afforded to young or feeble members of the school when the group is attacked or stressed in some fashion."

Harrison, R. J., Boice, R. C., Brownell, R. L. Jr.: "Reproduction in wild and captive dolphins." *Nature* **222**: 1143-1147 (1969).

H13,797/69

Among various types of dolphins, ulceration of the forestomach occurred during captivity, while the number of pregnancies decreased considerably.

Medway, W., Geraci, J. R., Klein, L. V.: "Hematologic response to administration of a corticosteroid in the bottle-nosed dolphin (*Tursiops truncatus*)."
J. Am. Vet. Med. Assoc. **157**: 563-565 (1970). J23,086/70

Geraci, J. R., Medway, W.: "Simulated field blood studies in the bottle-nosed dolphin *Tursiops truncatus*. 2. Effects of stress on some hematologic and plasma chemical parameters."
J. Wildl. Dis. **9**: 29-33 (1973). J20,650/73

Donkey. Bullard, R. W., Dill, D. B., Yousef, M. K.: "Responses of the burro to desert heat stress."
J. Appl. Physiol. **29**: 159-167 (1970). G78,189/70

Donkeys are extremely resistant to "desert heat stress," presumably because of a particularly efficient sweating and rehydration mechanism which largely depends upon EP secretion. Intradermal injection of EP causes local sweating in this species.

Maloiy, G. M. O.: "The effect of dehydration and heat stress on intake and digestion of food in the Somali donkey."
Environ. Physiol. Biochem. **3**: 36-39 (1973).

H79,366/73

Ferret. Donovan, B. T., Harris, G. W.: "The effect of pituitary stalk section on light-induced oestrus in the ferret."
J. Physiol. (Lond.) **131**: 102-114 (1956).

J6,721/56

In the ferret—as in most other species examined—simple section of the pituitary stalk is followed by regeneration of the vessels, as a result of which the initially suppressed light-induced estrus response reappears. Permanent separation of the hypophysis from the hypothalamus by interposition of waxed paper between the cut ends of the stalk abolishes the light-induced estrus and causes a decrease in thyroid and adrenal weight.

Gerbil. Goldblatt, D.: "Seizure disorder in gerbils."
Neurology (Minneapolis) **18**: 303-304 (1968). J22,710/68

In genetically predisposed gerbils, stressors (electroshock, photic or auditory stimulation) can precipitate seizures which greatly resemble epilepsy in man.

Hughes, R. E., Nicholas, P.: "Effects of caging on the ascorbic acid content of the adrenal glands of the guinea-pig and gerbil."
Life Sci. [II] **10**: 53-55 (1971).

G84,434/71

Ascorbic acid determinations in the adrenals of guinea pigs and gerbils suggest that "individual caging would appear to 'stress' the animals less than group caging" (8 refs.).

Hull, E. M., Langan, C. J., Rosselli, L.: "Population density and social, territorial, and physiological measures in the gerbil (*Meriones unguiculatus*)."
J. Comp. Physiol. Psychol. **84**: 414-422 (1973). J5,208/73

Mongolian gerbils possess a ventral sebaceous gland which they rub against low objects in their environment to mark territorial claims. "Crowding depressed several social interaction measures as well as body, ventral gland, and testis weights. In the mixed-sex groups, paired males and females had heaviest adrenal glands, ventral glands, and marking scores, as well as the highest reproductive rate. Mixed-sex crowding did not depress either social or physiological measures as much as did same-sex crowding."

Giraffe. Weyrauch, D.: "Über das Vorkommen von Parenchymzellteilen im Sinusoidsystem, im subendothelialen und interstitiellen Raum der Nebennierenrinde der Masai giraffe (*Giraffa camelopardalis tippelskirchii*)" (Parenchyme cell fractions of sinusoids in the subendothelial and interstitial spaces of the adrenal cortex in Masai giraffes [*Giraffa camelopardalis tippelskirchii*.])
Anat. Anz. **135**: 267-276 (1974).

J13,520/74

EM studies on Masai giraffes showed that certain adrenocortical cells can be found free within the sinusoids. Such a holocrine type of secretion may be enhanced by exposure to stress, although this has not yet been definitely proven.

Goat. Daniel, P. M., Prichard, M. M. L.: "The effects of pituitary stalk section in the goat."
Am. J. Pathol. **34**: 433-469 (1958).

C54,157/58

In goats, insertion of a wax plate between the cut ends of the pituitary stalk led to massive infarction of the anterior lobe, but certain areas always survived and underwent regeneration with mitotic proliferation. The posterior lobe became atrophic and showed histologic signs of degeneration. The pars intermedia became hypertrophic (44 refs.).

Adams, J. H., Daniel, P. M., Prichard, M. M. L.: "Transection of the pituitary stalk in the goat, and its effect on the volume of the pituitary gland." *J. Pathol. Bacteriol.* **87**: 1-14 (1964). G2,581/64

In goats, a nonirritant plate was inserted between the cut ends of the pituitary stalk. This caused massive infarcts in the pars distalis with no substantial regeneration. The infundibular process became extremely small, whereas the pars intermedia underwent hypertrophy.

Adams, J. H., Daniel, P. M., Prichard, M. M. L.: "The long-term effect of transection of the pituitary stalk on the volume of the pituitary gland of the adult goat." *Acta Endocrinol. (Kbh.)* **51**: 377-390 (1966). F65,157/66

In goats, transection of the pituitary stalk with prevention of anastomosis formation by a resin plate caused atrophy of the anterior lobe and infundibular process whereas the intermediate lobe underwent substantial hypertrophy.

Bryant, G. D., Linzell, J. L., Greenwood, F. C.: "Plasma prolactin in goats measured by radioimmunoassay: the effects of teat stimulation, mating behavior, stress, fasting and of oxytocin, insulin and glucose injections." *Hormones* **1**: 26-35 (1970). G76,754/70

Plasma LTH in goats, measured by radioimmunoassay, showed considerable rises after copulation (in both males and females), oxytocin injections and mild restraint, as well as during lactation. Conversely, fasting and insulin caused a fall in serum LTH (19 refs.).

Johke, T.: "Factors affecting the plasma prolactin level in the cow and the goat as determined by radioimmunoassay." *Endocrinol. Jap.* **17**: 393-401 (1970). H39,458/70

Radioimmunologic determinations in cows and goats led to the conclusion that various stressors (venipuncture, pain, restraint, emotional disturbances) elevate the plasma LTH

level, but milking is most effective in eliciting this response.

Guinea Pig. Winkler, G., Blobel, R., Tonutti, E.: "17-OH-Corticoidausscheidung bei Meerschweinchen mit Läsionen im mittleren Hypothalamus" (The effect of lesions in the middle region of the hypothalamus on 17-OH-corticoid excretion in guinea pigs). *Acta Neuroveg.* **20**: 230-237 (1959).

C76,659/59

Jonek, J., Stanosek, J., Krauze, M., Wacławczyk, H.: "Histochemische Untersuchungen über das Verhalten einiger Enzyme in Nebennieren bei Meerschweinchen nach chronischer Lärmeinwirkung" (Histochemical examinations of various enzymes in the adrenals of guinea pigs after chronic exposure to noise). *Z. Mikrosk. Anat. Forsch.* **73**: 174-186 (1965). G38,514/65

Chronic exposure of guinea pigs to noise (kind not clearly described) produced characteristic histochemical changes in various enzyme activities which gradually tended to disappear, and were ascribed to the alarm and resistance stages of the G.A.S.

Marino, A., Jovino, R., Cotrufo, M.: "Preliminary research on the interference between psychological stress and experimental pharmacologic arteriopathies in the guinea pig." *Cazz. Int. Med. Chir.* **70**: 120-122 (1965). J23,770/65

Luparello, T. J.: "Restraint and hypothalamic lesions in the production of gastroduodenal erosions in the guinea pig." *J. Psychosom. Res.* **10**: 251-254 (1966).

G43,819/66

Pegelman, S. G., Kanarik, U. K.: "Adaptive responses in guinea pigs under conditions of a prolonged cooling." *Sechenov Physiol. J. U.S.S.R.* **53** No. 10: 1212-1217 (1967) (Russian). J13,141/67

In guinea pigs, exposure to cold causes marked adrenal hypertrophy and ascorbic acid depletion with eosinopenia. Pretreatment with ascorbic acid reverses the eosinophil response and virtually blocks the loss of ascorbic acid from the adrenals.

Schaefer, K. E., McCabe, N., Withers, J.: "Stress response in chronic hypercapnia." *Am. J. Physiol.* **214**: 543-548 (1968).

F96,116/68

In guinea pigs, the prolonged respiratory acidosis produced by exposure to 15 percent

carbon dioxide in 21 percent oxygen caused a rise in blood corticoids and plasma FFA, with a depletion of adrenal cholesterol and a reduction of lymphopenia.

Ludwig, W. M., Lipkin, M.: "Biochemical and cytological alterations in gastric mucosa of guinea pigs under restraint stress." *Gastroenterology* **56**: 895-902 (1969).

G66,300/69

Joseph, S. A., Knigge, K. M., Voloschin, L.: "Effects of isolation of the hypothalamo-pituitary unit in newborn guinea pigs." *Neuroendocrinology* **4**: 42-50 (1969).

H8,974/69

In newborn guinea pigs, deafferentation of the hypothalamus with a modified Halász knife showed that within about three months, "growth and gonadal function were most seriously impaired; development of thyroid and adrenal function was unaffected in male animals and only moderately affected in females. The results indicate that those RF-producing neurones associated with growth hormone and the gonadotrophins may require afferent neural connections for their normal maturation, while RF-producing neurones associated with thyrotrophin and corticotrophin may develop normally in the isolated hypothalamo-pituitary unit."

Hase, T., Scarborough, E. S.: "Development of stress ulcer in rats and guinea pigs by mechanical rotation." *J. Appl. Physiol.* **30**: 580-582 (1971).

G84,313/71

In guinea pigs and rats, stress ulcers of the stomach can be produced by mechanical rotation in a specially-designed chamber.

Hughes, R. E., Nicholas, P.: "Effects of caging on the ascorbic acid content of the adrenal glands of the guinea-pig and gerbil." *Life Sci. [II]* **10**: 53-55 (1971).

G84,434/71

Ascorbic acid determinations in the adrenals of guinea pigs and gerbils suggest that "individual caging would appear to 'stress' the animals less than group caging" (8 refs.).

Dalle, M., Delost, P.: "Changes in the concentrations of cortisol and corticosterone in the plasma and adrenal glands of the guinea-pig from birth to weaning." *J. Endocrinol.* **63**: 483-488 (1974).

H98,345/74

Hamsters. Deane, H. W., Lyman, C. P.: "Body temperature, thyroid and adrenal cortex of hamsters during cold exposure and

hibernation, with comparisons to rats." *Endocrinology* **55**: 300-315 (1954). B97,428/54

In both hibernating and nonhibernating Syrian hamsters, exposure to cold causes no significant adrenal enlargement or histologic evidence of hyperactivity similar to that produced in rats. However, the hamster adrenal is sensitive to other stressors.

Raths, P., Schulze, W.: "Die Nebennieren des Goldhamsters im Winterschlaf und bei anderen Aktivitätszuständen" (The adrenals of the golden hamster during hibernation and other activities). *Z. Biol.* **109**: 233-243 (1957).

C36,859/57

Detailed description of histologic changes in the adrenal medulla and cortex of the golden hamster during hibernation, upon awakening from hibernation and under anesthesia induced by cold.

Ehrentheil, O. F., Reyna, L. J., Yerganian, G., Chen, E. T.: "Studies in stress glycosuria. I. Prolonged glycosuria in Chinese hamsters after repeated stress." *Diabetes* **13**: 83-86 (1964).

F1,978/64

Chinese hamsters unfamiliar with each other started fighting when placed together. This resulted in glycosuria which continued for two weeks, after daily repeated fights. Both catecholamine and corticoid discharge during the G.A.S. may be of etiologic significance. The findings could be pertinent to the development of stress-induced diabetes.

Frenkel, J. K., Cook, K., Grady, H. J., Pendleton, S. K.: "Effects of hormones on adrenocortical secretion of golden hamsters." *Lab. Invest.* **14**: 142-156 (1965).

G26,921/65

Detailed description of the adrenal response to stress, ACTH, corticoids, metyrapone, amphenone and other conditioning agents in hamsters (34 refs.).

Canguilhem, B., Bloch, R.: "Evolution saisonnière de l'élimination des hormones surréaliennes chez un hibernant, *Cricetus cricetus*" (Seasonal evolution of adrenal hormone excretion in a hibernating animal, *Cricetus cricetus*). *Arch. Sci. Physiol.* **21**: 27-44 (1967).

G46,415/67

In the hamster (*Cricetus cricetus*), no seasonal variations in catecholamine output are noted, although such excretion diminishes during adaptation to cold and may last four months, even if the animals are placed in surroundings with normal room temperature (23°C). On the other hand, urinary glucocor-

ticoid and aldosterone elimination is subject to definite seasonal changes that are independent of ambient temperature.

Arcari, G., Gaetani, M., Glässer, A. H., Turolla, E.: "Restraint-induced gastric ulcers in the golden hamster." *J. Pharm. Pharmacol.* **20**: 73 (1968). J22,648/68

Noble, G. A.: "Leishmania braziliensis: physical and chemical stress in hamsters." *Exp. Parasitol.* **29**: 30-32 (1971).

G81,736/71

In hamsters, various stressors, and particularly restraint, significantly diminished resistance to inoculation with *Leishmania braziliensis*.

Sokolov, V. I.: "The reaction of the adrenal cortex of intact and castrated rodents to formalin stress." *Zh. Evol. Biokhim. Fiziol.* **10** No. 2: 171-175 (1974) (Russian). Engl. transl.: *J. Evol. Biochem. Physiol.* **10**: 149-153 (1974). J18,986/74

Adrenocortical mitotic activity in hamsters and rabbits stressed by formalin is altered after orchidectomy.

Al-Lami, F., Farman, N.: "Ultrastructural and histochemical study of the adrenal medulla in normal and cold-stressed Syrian hamsters." *Anat. Rec.* **181**: 113-129 (1975).

J19,965/75

Hedgehog. Suomalainen, P.: "Further investigations on the physiology of hibernation." *Proc. Finn. Acad. Sci. & Letters*, pp. 131-144. Helsinki, 1953. C852/53

The changes characteristic of hibernation in the hedgehog are compared to those of the G.A.S. Relationships between these two phenomena are discussed.

Lindner, E.: "Die Sacculi Mitochondriales der Diskochondrien und Sphaerochondrien in der Nebennierenrinde vom Igel (*Erinaceus europaeus L.*)" (The mitochondrial sacculi in discochondria and sphaerochondria of the adrenal cortex among hedgehogs [*Erinaceus europaeus L.*]). *Z. Zellforsch. Mikrosk. Anat.* **72**: 212-235 (1966). G39,703/66

In the hedgehog during hibernation, despite diminished function, the adrenal mitochondria retain their EM characteristics—discochondria and sphaerochondria are clearly demonstrable—although the amount of dense matrix is increased.

Horse. Alexander, F., Ash, R. W.: "The effect of emotion and hormones on the con-

centration of glucose and eosinophils in horse blood." *J. Physiol.* **130**: 703-710 (1955). C51,993/55

Handling and repeated venipuncture as well as EP in doses adequate to produce hyperglycemia failed to elicit eosinopenia in ponies, whereas ACTH in adequate dosages did induce this effect. Insulin hypoglycemia and histamine likewise caused eosinopenia in this species.

Forenbacher, S., Rode, B.: "Investigations on the role played by the insular apparatus in the pathogenesis of paralytic myoglobinuria in the horse." *Zentralbl. Veterinaermed.* **8**: 1-11 (1961). D12,281/61

Morphologic changes in the pancreas of the horse after exposure to a variety of agents may represent stress effects, although this has not been proven.

Irvine, C. H. G.: "Thyroxine secretion rate in the horse in various physiological states." *J. Endocrinol.* **39**: 313-320 (1967). F91,501/67

By use of labeled thyroxine, it has been found that adaptation to cold and muscular training increases the thyroxine secretion rate of the horse.

James, V. H. T., Horner, M. W., Moss, M. S., Rippon, A. E.: "Adrenocortical function in the horse." *J. Endocrinol.* **48**: 319-335 (1970). H32,502/70

In the horse, surgical trauma or hypoglycemia increases plasma cortisol, whereas exercise is much less effective in this respect. The cortisol variations are not necessarily associated with changes in the eosinophil count. "It is concluded that the mechanisms of control of adrenocortical function in the horse are not dissimilar to those described for other mammalian species."

Dieterich, R. A., Helleman, D. F.: "Hematology, biochemistry, and physiology of environmentally stressed horses." *Can. J. Zool.* **51**: 867-873 (1973). J24,387/73

Marsupial. Hopwood, P. R., King, S.: "Marsupial stress syndrome." *Aust. Vet. J.* **48**: 71-72 (1972). J20,508/72

Needham, A. D., Dawson, T. J., Hales, J. R. S.: "Forelimb blood flow and saliva spreading in the thermoregulation of the red kangaroo, *Megaleia rufa*." *Comp. Biochem. Physiol. [A]* **49**: 555-565 (1974).

H93,882/74

Mink. Gilbert, F. F., Bailey, E. D.: "The

effect of visual isolation on reproduction in the female ranch mink." *J. Mammal.* **48**: 113-118 (1967). J11,146/67

Isolation of female ranch minks from other members of the species inhibits sexual development and fertility.

Gilbert, F. F., Bailey, E. D.: "Visual isolation and stress in female ranch mink particularly during the reproductive season." *Can. J. Zool.* **47**: 209-212 (1969). J20,525/69

"Visual isolation is apparently more stressful to female mink during the anoestrous period but reduces stress during oestrus and pregnancy. The increased adrenal steroid output of control mink as part of the stress syndrome during the critical reproductive period might be responsible for increased *in utero* losses. But increased adrenocortical output associated with the stress of *long term* visual isolation might result in insufficient gonadal stimulation resulting in fewer pregnancies."

Mongoose. Stemmermann, G. N., Hayashi, T.: "A survey of the normal and morbid anatomy of the Hawaiian feral mongoose." *Am. J. Pathol.* **55**: 67a-68a (1969). H13,927/69

Among Hawaiian feral mongooses, acute stress ulcers are common and probably related to the method of capture. Yet, the finding of healing ulcers shows that these lesions also occur in the wild.

Monkey. Bahn, R. C., Glick, D.: "Studies in histochemistry: effects of stress conditions, ACTH, cortisone and desoxycorticosterone on the quantitative histological distribution of ascorbic acid in adrenal glands of the rat and monkey." *Endocrinology* **54**: 672-684 (1954). B94,671/54

In monkeys (*M. rhesus*, *M. cynomolgus*), as well as in rats, various stressors (cold, struggling, ether anesthesia, hypoxia and hyperthermia) cause a decrease in the ascorbic acid content of the outer fasciculata and reticularis zones of the adrenal cortex. Intraperitoneal ACTH produces the same result.

Mason, J. W., Harwood, C. T., Rosenthal, N. R.: "Influence of some environmental factors on plasma and urinary 17-hydroxycorticosteroid levels in the rhesus monkey." *Am. J. Physiol.* **190**: 429-433 (1957). C42,224/57

Adams, J. H., Daniel, P. M., Prichard, M. M. L.: "Volume of the infarct in the

anterior lobe of the monkey's pituitary gland shortly after stalk section." *Nature* **198**: 1205-1206 (1963). D69,623/63

Marsh, J. T., Lavender, J. F., Chang, S. S., Rasmussen, A. F.: "Poliomyelitis in monkeys: decreased susceptibility after avoidance stress." *Science* **140**: 1414-1415 (1963).

D69,198/63

In monkeys (*M. cynomolgus*), "avoidance stress" prior to inoculation with type I poliovirus protected against the fatal effect of the infection. The circulating lymphocytes decreased significantly during stress. These findings contrast sharply with earlier observations in which stressors diminished the resistance of mice to virus infection. However, the schedule of exposure to stress may be important (10 refs.).

Meier, R. M., Greenhoot, J. H., Shonley, I., Goodman, J. R., Porter, R. W.: "Sex differences in the serum cholesterol response to stress in monkeys." *Nature* **199**: 812-813 (1963).

E24,291/63

Stress caused by restraint decreased serum cholesterol in rhesus monkeys of both sexes, but particularly in males. A review of earlier data shows that some researchers found an increase, others a decrease, in plasma cholesterol levels in both animals and man, but the reasons for these discrepancies are not known (11 refs.).

Elmadjian, F., Forchielli, E.: "Characterization of hormonal steroids of the chimpanzee: changes observed in adrenal cortical function during simulated and actual space flight." In: Martini, L. and Pecile, A., *Hormonal Steroids. Biochemistry, Pharmacology, and Therapeutics*, Vol. 2, pp. 535-544. New York and London: Academic Press, 1965.

E5,498/65

Detailed report on changes in the urinary excretion and blood level of various steroids (corticoids, estrogens, androgens and so on) in chimpanzees during actual or simulated space flights. "Interpretation of the above data is difficult due to the varying degrees of time-lapse from the point of termination of the stress to the time of sampling."

St. Clair, R. W., MacNinch, J. E., Middleton, C. C., Clarkson, T. B., Lofland, H. B.: "Changes in serum cholesterol levels of squirrel monkeys during importation and acclimation." *Lab. Invest.* **16**: 828-832 (1967).

H1,895/67

In squirrel monkeys (*Saimiri sciureus*) captured in Colombia, serum cholesterol rose

significantly after transportation to North Carolina. This response was much less obvious in animals kept in a semisecluded environment than in those caged in laboratories with relatively high noise levels, and in frequent contact with men. The cholesterol changes could be completely accounted for by a similar alteration in β -lipoprotein cholesterol without any alteration in α -lipoprotein cholesterol. "It is suggested that the observed changes in serum cholesterol may reflect the squirrel monkeys' reaction to 'stress' resulting from changes in environment." However, the relative importance of relocation, captivity, noise and contact with men is difficult to appraise.

Hill, C. W., Greer, W. E., Felsenfeld, O.: "Psychological stress, early response to foreign protein, and blood cortisol in vervets." *Psychosom. Med.* **29**: 279-283 (1967).

G48,085/67

In vervet monkeys (*Cercopithecus aethiops*) exposed to psychogenic stress (noise, light, handling) serum cortisol levels rose considerably, and antibody formation to bovine serum albumin was delayed and diminished.

McHugh, P. R., Smith, G. P.: "Negative feedback in adrenocortical response to limbic stimulation in *Macaca mulatta*." *Am. J. Physiol.* **213**: 1445-1450 (1967).

F92,213/67

In conscious chair-confined *Macaca mulatta* the rise in plasma 17-OHCS following intravenous administration of cortisol was modified by stimulation of certain brain lesions with bipolar electrodes. The results obtained furnished "evidence for a negative feedback effect of injected hydrocortisone on the 17-OHCS response to amygdaloid stimulation but not to hypothalamic stimulation, and suggest the presence of a neural mechanism for negative feedback located functionally between amygdala and hypothalamus."

Lang, C. M.: "Effects of psychic stress on atherosclerosis in the squirrel monkey (*Saimiri sciureus*)."
Proc. Soc. Exp. Biol. Med. **126**: 30-34 (1967). F90,255/67

About two years of exposure to restraint, alone or combined with conditioned avoidance, accelerated the development of atherosclerosis, increased urinary 17-KS excretion and raised serum cholesterol.

Wheeler, T. E., New, A. E.: "A study of blood serum potassium concentration and stress in the squirrel monkey (*Saimiri*

sciureus)."
NAM1-1041. U.S. Naval Aerosp. Med. Inst. 1-8 (1968). J23,751/68

Brown, G. M., Grotta, L. J., Penney, D. P., Reichlin, S.: "Adrenal regulation in the wild captive squirrel monkey: a model of chronic stress." *Can. Psychiatr. Assoc. J.* **15**: 425-431 (1970). G78,935/70

Brown, G. M., Grotta, L. J., Penney, D. P., Reichlin, S.: "Pituitary-adrenal function in the squirrel monkey." *Endocrinology* **86**: 519-529 (1970). H22,206/70

Radiosteroid assays indicate that "the major steroid in squirrel monkey plasma is cortisol, that the values in resting, undisturbed caged animals are indeed uniquely high (405 $\mu\text{g}/100 \text{ ml} \pm \text{SE } 43$), and are capable of increasing in response to capture (672 $\mu\text{g}/100 \text{ ml} \pm \text{SE } 72$) and chair restraint (1024 $\mu\text{g}/100 \text{ ml} \pm \text{SE } 52$), that the bound fraction of plasma cortisol is not greater than in other primates, that the turnover rate of cortisol is extremely high (30 mg/day in chair restrained animals), that adrenal function in these animals is inhibited only by relatively large doses of dexamethasone, and that they are relatively unresponsive to exogenous ACTH."

Brown, G. M., Schalch, D. S., Reichlin, S.: "Patterns of growth hormone and cortisol responses to psychological stress in the squirrel monkey." *Endocrinology* **88**: 956-963 (1971). H37,353/71

In squirrel monkeys, various stressors (capture, chair restraint, intense sound and aversive conditioning) increase plasma STH and cortisol levels but the two responses are not parallel and presumably are regulated by diverse mechanisms. In the case of chair restraint, STH values fall to resting levels whereas cortisol continues to rise.

Brown, G. M., Schalch, D. S., Reichlin, S.: "Hypothalamic mediation of growth hormone and adrenal stress response in the squirrel monkey." *Endocrinology* **89**: 694-703 (1971). H45,128/71

In squirrel monkeys, the stress of emotional excitement (chair restraint, capture) increased plasma STH and corticoid levels, but the two changes were not parallel. The STH response to capture and ether was blocked by small lesions in either the anterior or posterior ME, while adrenal reaction to capture and chair restraint were blocked by lesions in the posterior ME. STH responses to ether were enhanced by midline optic chiasm lesions. However, great individual

variations interfered with the precise evaluation of these data.

Penney, D. P., Brown, G. M.: "The fine structural morphology of adrenal cortices of normal and stressed squirrel monkeys." *J. Morphol.* **143**: 447-466 (1971).

G85,767/71

In squirrel monkeys, EM observations show a close correlation between hyperdevelopment of the agranular reticulum and increased plasma cortisol levels during the stress of chair restraint. There is also "depletion and disorientation of membranes both of the agranular endoplasmic reticulum and mitochondria and a loss of ribosomes, lysosomes and, to some degree, intracellular lipid."

Baumann, H., Urmantscheeva, T. G., Wolter, F., Martin, G., Gurk, C.: "Multivariate evoked potential-Studien zur Quantifizierung zentralnervöser Adaptationsprozesse unter Stresseinfluss bei Rhesusmacacen" (Multivariate evoked potential studies for the qualification of central nervous adaptation processes under the influence of stress in Rhesus macaca). *Acta Biol. Med. Ger.* **31**: 415-422 (1973).

H83,654/74

Electric stimulation of the hypothalamus in rhesus monkeys caused a rise in plasma 17-OHCS, especially during the initial excitement. Although increases were obtained after stimulation of various sites scattered throughout the anterior, tuberal and posterior parts of the lateral hypothalamus, plasma STH was elevated only when posterior sites were stimulated. This pattern of a smaller hypothalamic area for STH than for ACTH release has also been observed in the rat,

cat and squirrel monkey, and is probably a general principle of organization.

"Monkeys agree—noise is upsetting!" *Med. Times* **102**: 71-76 (1974).

J17,048/74

Review on the effect of noise (industrial, rock music, intermittent gunfire) upon rhesus monkeys. Blood cortisol levels showed an initial rise followed by a drop during the third hour of exposure "despite behavioral indications that the animals continued to be stressed." [Based on an earlier article by Watson (H.S.).]

Michailov, M. L., Gnüchtel, U., Nitschkoff, S., Baumann, R., Gnauck, G.: "Verhalten von Fettsäuren im Blutplasma von Affen nach Einwirkung kurzfristiger Stressoren" (Plasma fatty acid changes in baboons after acute stress). *Acta Biol. Med. Ger.* **32**: 675-680 (1974).

J16,605/74

In baboons (*Papio hamadryas*), various stressors (restraint, jealousy) cause a rise in unsaturated plasma FFA, especially oleic acid, and a relative decrease in saturated FFA, particularly palmitinic acid.

Mouse. Anthony, A.: "Effects of noise on eosinophil levels of audiogenic-seizure-susceptible and seizure-resistant mice." *J. Acoust. Soc. Am.* **27**: 1150-1153 (1955).

E80,679/55

"A prolonged eosinopenia occurs with several successive noise bursts at a moderately low level (ca 250 eosinophils/cu mm blood) in seizure-resistant mice and at lower levels (ca 100 eosinophils/cu mm blood) in mice which experience convulsions during treatment. It was concluded that noise stimulation acts as a mild stress stimulus and is harmful only when it results in the production of fatal convulsions."

Bevan, W.: "Sound-precipitated convulsions: 1947 to 1954." *Psychol. Bull.* **52**: 473-504 (1955).

D78,855/55

Review of genetic and stress factors causing audiogenic convulsions. It is deplored that "despite general preference for a physiological model, nothing has been done to assay systematically physiological differences among susceptible and nonsusceptible animals. Although electroshock convulsions have been discussed within the framework of Selye's adaptation syndrome hypothesis, and although audiogenic seizures have been regarded as a stress phenomenon by both physiologically and psychologically biased in-

vestigators, no vigorous attempt to exploit Selye's logic has been made for the latter phenomenon" (145 refs.).

Anthony, A.: "Changes in adrenals and other organs following exposure of hairless mice to intense sound." *J. Acoust. Soc. Am.* **28**: 270-274 (1956). E82,034/56

On the basis of observations in hairless mice, it was concluded that both immobilization and intense sound vibrations on the skin surface can act as stressors. When the sound is very intense, the systemic response is similar to that seen after skin burns. Here, heat and not sound is considered to be the responsible stressor.

Anthony, A., Marks, B.: "Noise-induced convulsions in mice." *Experientia* **15**: 320-321 (1959). E80,668/59

Certain strains of mice are considered to be "seizure resistant," but noise sometimes caused convulsions among mongrel mice of the Swiss Albino type. The incidence of convulsions was highest among mice exposed to intense high frequency noise.

Smith, L. W., Molomut, N., Gottfried, B.: "Effect of subconvulsive audiogenic stress in mice on turpentine induced inflammation." *Proc. Soc. Exp. Biol. Med.* **103**: 370-372 (1960). C81,345/60

Thiessen, D. D., Nealey, V. G.: "Adrenocortical activity, stress response and behavioral reactivity of five inbred mouse strains." *Endocrinology* **71**: 267-270 (1962). D29,041/62

Bronson, F. H., Eleftheriou, B. E.: "Adrenal responses to crowding in *Peromyscus* and C57BL/10J mice." *Physiol. Zool.* **36**: 161-166 (1963). D63,122/63

Southwick, C. H.: "*Peromyscus leucopus*: an interesting subject for studies of socially induced stress responses." *Science* **143**: 55-56 (1964). F35/64

The white-footed mouse is particularly suitable for the study of social interactions in stress physiology. It possesses "tolerance of very high cage densities among social congeners; marked behavioral intolerance among social strangers; exceptionally large adrenal glands; and adrenal and eosinophil responses sensitive to social disturbance."

Levine, S., Treiman, D. M.: "Differential plasma corticosterone response to stress in four inbred strains of mice." *Endocrinology* **75**: 142-144 (1964). F15,512/64

Friedman, S. B., Ader, R.: "Parameters relevant to the experimental production of "stress" in the mouse." *Psychosom. Med.* **27**: 27-30 (1965). G26,082/65

"Merely moving mice from standard laboratory cages to experimental cages resulted in a significant decrease in weight gain. Mice subjected to periodic shock preceded by a stimulus light lost a greater amount of weight during the observation period than mice subjected to any of the other experimental conditions."

Castellion, A. W., Swinyard, E. A., Goodman, L. S.: "Effect of maturation on the development and reproducibility of audiogenic and electroshock seizures in mice." *Exp. Neurol.* **13**: 206-217 (1965). J22,995/65

Foss, C. R., Horvath, S. M.: "Reactions of wild and albino mice in response to forced swimming." *Proc. Soc. Exp. Biol. Med.* **120**: 588-592 (1965). F59,402/65

The ability of wild and domestic albino mice to swim until exhaustion was more limited in water of 20°C than 37°C. The drop in colonic temperature was an excellent indication of exhaustion in water of 28°C or less; but colonic temperature remained normal or even rose at higher temperatures. There was no significant difference in either colonic temperature or endurance between the two strains.

Lehmann, A.: "Action de crises répétées d'épilepsie acoustique sur le taux de noradrénaline des zones corticales et sous-corticales du cerveau de souris" (Effects of repeated acoustic epileptic seizures on noradrenaline levels of the cortical and subcortical zones of the brain in mice). *C.R. Soc. Biol. (Paris)* **159**: 62-64 (1965).

F44,990/65
In seizure-susceptible mice, repeated exposure to sound produces eventually fatal convulsive attacks. Mortality is also increased by reserpine, but is decreased by MAO inhibitors. Audiogenic seizures, especially if they are lethal, greatly diminish the NEP content of the brain, particularly in its subcortical layer. In conjunction with the observation that MAO inhibitors protect, it may be assumed that NEP depletion is the cause of lethality in audiogenic seizures. However, oft repeated exposure to sound elicits convulsions of diminishing intensity and eventually complete insensitivity ensues. Yet even in these resistant animals, the brain NEP concentra-

tion is low. Perhaps lethality depends upon a particularly rapid catecholamine loss.

Schlesinger, K., Boggan, W., Freedman, D. X.: "Genetics of audiogenic seizures: I. Relation to brain serotonin and norepinephrine in mice." *Life Sci.* **4**: 2345-2351 (1965).

G36.091/65

The brain levels of NEP and 5-HT were highest in strains of mice with the greatest susceptibility to audiogenic seizures.

Rabbit. Kracht, J., Kracht, U.: "Zur Histopathologie und Therapie der Schreckthyrotoxikose des Wildkaninchens" (The histopa-

thology and therapy of fright thyrotoxicosis in wild rabbits). *Virchows Arch. [Pathol. Anat.]* **321**: 238-274 (1952). B68,863/52

In some strains of wild rabbits, fear induced by a pursuing dog or man causes "stress thyrotoxicosis" with histologic signs of thyroid hyperactivity and exophthalmos.

Kracht, J., Spaethe, M.: "Über Wechselbeziehungen zwischen Schilddrüse und Nebennierenrinde. II. Mitteilg. Untersuchungen über den 'Hypophysenhemmstoff' p-Oxypropiophenon" (Interrelation between the thyroid and the adrenal cortex. II. Report: Studies on the "hypophyseal inhibitor" p-oxypropiophenone). *Virchows Arch. [Pathol. Anat.]* **323**: 629-644 (1953). B85,143/53

Wild rabbits respond to frightening stimuli not only with adrenocortical enlargement, but also with a marked discharge of TTH which causes thyroid hypertrophy. This peculiar response can be prevented by hypophysectomy or methylthiouracil. p-Oxypropiophenone is inactive.

Kracht, J., Spaethe, M.: "Über Wechselbeziehungen zwischen Schilddrüse und Nebennierenrinde. III. Mitt. Die thyreotrope Belastungsreaktion" (Interrelation between the thyroid and the adrenal cortex. III. Report: The thyrotropic stress reaction). *Virchows Arch. [Pathol. Anat.]* **324**: 83-109 (1953). B87,399/53

In wild rabbits, fear produces an acute discharge of TTH, often with an actual inhibition of ACTH secretion. "The symptomatology and the cause of fear thyrotoxicosis can be classified in terms of the phases of the alarm reaction, resistance and exhaustion (Selye). Increased thyrotropic function causes inhibition of ACTH secretion."

Griffiths, M. E., Calaby, J. H., McIntosh, D. L.: "The stress syndrome in the rabbit." *C.S.I.R.O. Wildl. Res.* **5**: 134-148 (1960).

D12,295/60

Detailed description of the stress syndrome in the wild rabbit, in which adrenal ascorbic acid content is extremely variable and cortical lipid granules increase after the animal has been kept in the laboratory for a "settling-in period." Cold has little effect on cortical ascorbic acid or lipid droplets, but subcutaneous formalin causes a threefold increase in adrenal size. Noise gives "cross resistance" to cold, but formalin does not.

Schäfer, H., Voss, C., Henschel, H. J., Hartmann, N.: "Jodtyrosin-Dejodesen im Stoffwechsel der Schilddrüsen-Hormone (Io-

dtyrosine deiodases in the metabolism of thyroid hormones). *Hoppe Seylers Z. Physiol. Chem.* **341**: 268-283 (1965).

J24,473/65

In wild rabbits, experimentally induced fright causes characteristic changes in the iodotyrosine deiodase content of various tissues which may be involved in the mechanism of stress-induced hyperthyroidism in animals and man (37 refs.).

Lybeck, H., Leppäläluoto, J., Virkkunen, P.: "The effect of pertinent and non-pertinent stimuli on the secretions of thyrotropin and corticotropin." *Int. J. Neurosci.* **5**: 47 (1973).

J19,727/73

ACTH secretion rises under the influence of cold in both the rat and the rabbit, but TTH release remains unchanged in the latter. [If this difference does depend upon strain in rabbits, then the stressor effect of cold varies from that of fear, since some wild rabbits develop acute hyperthyroidism when chased by a dog (H.S.).]

Roussel, A., Daniel, J. Y., Assenmacher, I.: "Les glucocorticostéroïdes circulants du Lapin, et leurs fluctuations nyctémérales" (Circulating glucocorticoids and circadian variations in rabbits). *C.R. Acad. Sci. (Paris)* **277**: 341-344 (1973). J6,395/73

In rabbits, both plasma corticosterone and cortisol undergo circadian variations, with a peak during the day and a drop at the end of the night. However, the two corticoids do not show complete parallelism.

Khitrov, N. K., Demurov, E. A.: "Concerning the method of acute experiments on rabbits." *Patol. Fiziol. Éksp. Ter.* **10** No. 2: 76-78 (1974) (Russian).

transl.: *J. Evol. Biochem. Physiol.* **10**: 149–153 (1974). J18,986/74

Adrenocortical mitotic activity in hamsters and rabbits stressed by formalin is altered after orchidectomy.

Rat. Hammett, F. S.: "Studies of the thyroid apparatus. V. The significance of the comparative mortality rates of parathyroidectomized wild Norway rats and excitable and non-excitable albino rats." *Endocrinology* **6**: 221–229 (1922). 13,183/22

Rogers, P. V., Richter, C. P.: "Anatomical comparison between the adrenal glands of wild Norway, wild Alexandrine and domestic Norway rats." *Endocrinology* **42**: 46–55 (1948). B4,924/48

In general, wild rats have proportionally much heavier adrenal glands than domesticated strains, presumably because the latter are more protected against the stressors of competitive life. The reduced size of the adrenals in the laboratory rats can be ascribed to comparative cortical atrophy, the medulla not being affected.

Covian, M. R.: "Role of emotional stress in the survival of adrenalectomized rats given replacement therapy." *J. Clin. Endocrinol. Metab.* **9**: 678 (1949). B48,388/49

In contrast to domesticated strains, wild Norway rats cannot be indefinitely maintained on sodium chloride after adrenalectomy and are particularly sensitive to the fatal effects of electroshock, "indicating that the emotional state of captive wild rats is such that therapy sufficient to offset the loss of adrenals in laboratory rats is insufficient to keep the wild rats alive."

Richter, C. P.: "Domestication of the Norway rat and its implications for the problem of stress." In: Wolff, H. G., Wolf, S. G. Jr. et al., *Life Stress and Bodily Disease*, pp. 19–47. Baltimore: Williams & Wilkins, 1950. B51,893/50

The organ weights of wild Norway rats (large adrenals, small thymus and so on) as well as many functional characteristics resemble those typical of the G.A.S. and in this respect differ from those of domesticated rats. Presumably, this can be ascribed to the more sheltered existence of the laboratory animals.

Richter, C. P., Rogers, P. V., Hall, C. E.: "Failure of salt replacement therapy in adrenalectomized recently captured wild Nor-

way rats." *Endocrinology* **46**: 233–242 (1950). D92,528/50

Unlike domesticated rats, wild Norways could not be maintained with sodium chloride after adrenalectomy, presumably because of their violent reactions to the usual stressor stimuli of daily life.

Woods, J. W.: "Differences in adrenal response to adverse conditions in wild and domesticated Norway rats." *Fed. Proc.* **12**: 159 (1953). B78,653/53

Wild and domesticated Norway rats were exposed to various stressors (cold, noise, fighting). "The results show that the wild rat endures the conditions of these experiments without a decrease in the amount of assayable ascorbic acid or stainable lipid in his adrenal cortex while results with the white rat are in agreement with the numerous reports of ascorbic acid and lipid depletion following similar stimulation." As indicated by ascorbic acid depletion, the adrenals of the wild rat are less sensitive than those of domesticated rats to traumatization of the intestines, hemorrhage, ether anesthesia, unilateral adrenalectomy or even ACTH administration.

Greenberg, L. A., Lester, D.: "The effect of alcohol on audiogenic seizures of rats." *Q. J. Stud. Alcohol* **14**: 385–389 (1953). J23,511/53

In rats, audiogenic seizures were largely inhibited by moderate ethanol intake.

Sines, J. O.: "Experimental production and control of stomach lesions in the rat." *J. Psychosom. Res.* **4**: 297–300 (1960). J23,258/60

Certain strains of rats are especially susceptible to restraint gastric ulcers. Such lesions can be controlled by anticholinergics but are increased by large doses of chlorpromazine. This "suggests that stomach lesion development in the rat is at least in part dependent upon parasympathetic hyperactivity."

Cole, J.: "A stress reaction in rats (*Rattus norvegicus*)."*Arzneim. Forsch.* **14**: 1048–1050 (1964). F22,700/64

Valtin, H., Schroeder, H. A.: "Familial hypothalamic diabetes insipidus in rats (Brattleboro strain)." *Am. J. Physiol.* **206**: 425–430 (1964). F1,711/64

In the strain of rats with familial hypothalamic diabetes insipidus, which can be corrected by vasopressin, the ability to concen-

urate urine in response to stress, dehydration, hypertonic saline or nicotine is greatly impeded.

Mikhail, A. A., Broadhurst, P. L.: "Stomach ulceration and emotionality in selected strains of rats." *J. Psychosom. Res.* **8**: 477-479 (1965). G27,799/65

Sackler, A. M., Weltman, A. S., Kreger, A. S.: "Metabolic and endocrine aspects of audiogenic-seizure susceptibility in female rats." *Exp. Med. Surg.* **24**: 258-269 (1966). F87,334/66

McCann, S. M., Antunes-Rodrigues, J., Nallar, R., Valtin, H.: "Pituitary-adrenal function in the absence of vasopressin." *Endocrinology* **79**: 1058-1064 (1966).

F74,055/66

In rats having hereditary hypothalamic diabetes insipidus and lacking vasopressin, stressors (ether, bleeding) raised plasma corticosterone, but to a significantly lesser extent than in normal controls. CRF activity in the stalk-ME and the pituitary ACTH concentration were essentially the same in the two strains. Presumably, "although vasopressin is not the corticotrophin-releasing factor, it may play a small role in adrenal cortical response to stress."

Weltman, A. S., Sackler, A. M.: "Timidity and metabolic elimination patterns in audiogenic-seizure susceptible and resistant female rats." *Experientia* **22**: 627-629 (1966).

G16,051/66

There is a positive relationship between timidity and seizure susceptibility in rats exposed to "auditory stress." At the same time, there is an increase in diuresis and the quantity of feces.

Arimura, A., Saito, T., Bowers, C. Y., Schally, A. V.: "Pituitary-adrenal activation in rats with hereditary hypothalamic diabetes insipidus." *Acta Endocrinol. (Kbh.)* **54**: 155-165 (1967). F76,127/67

In rats with hereditary hypothalamic diabetes insipidus, the basic plasma corticosterone concentrations are normal, and their reactions to stressors (ether, histamine, vasopressin, acetylcholine) are also within normal limits. Since these polyuric rats lack vasopressin, the latter is unlikely to be the physiologic CRF. On the other hand, the CRF content of the hypothalamus of these hereditarily stigmatized rats is normal, although their posterior lobe contains no CRF but a normal amount of ACTH.

Ader, R., Friedman, S. B., Grota, L. J.: "'Emotionality' and adrenal cortical function: effects of strain, test, and the 24-hour corticosterone rhythm." *Anim. Behav.* **15**: 37-44 (1967). G46,135/67

Weltman, A. S., Sackler, A. M., Owens, H.: "Effects of levels of audiogenic-seizure susceptibility on endocrine function of rats." *Physiol. Behav.* **3**: 281-284 (1968).

H5,154/68

Rats susceptible to audiogenic seizures developed adrenal hypertrophy and thymus involution upon exposure to the stressor effect of an alarm bell.

Sines, J. O., McDonald, D. G.: "Heritability of stress-ulcer susceptibility in rats." *Psychosom. Med.* **30**: 390-394 (1968).

G60,432/68

Martin, M. S., Martin, F., André, C., Lambert, R.: "Sélection du Rat Wistar en fonction de sa sensibilité à l'ulcère de contrainte" (Selection of Wistar rats as a function of sensitivity to restraint ulcers). *C.R. Soc. Biol. (Paris)* **162**: 2126-2128 (1968). H14,408/68

Selective breeding of rats to obtain strains that are resistant or sensitive to restraint ulcers.

Monastyrskaya, B. I., Prakh'e, I. B., Khaunina, R. A.: "The influence of sound on the hypophysis-adrenal system of healthy rats and those genetically highly sensitive to sound." *Bull. Éksp. Biol. Med.* **68** No. 12: 36-39 (1969) (Russian). J22,841/69

In rats genetically predisposed to audiogenic convulsions, hypertrophy of the pituitary and adrenals is manifest upon exposure to the stress of sound.

Ader, R.: "Adrenocortical function and the measurement of 'emotionality.'" *Ann. N.Y. Acad. Sci.* **159**: 791-805 (1969).

H18,024/69

Plasma and adrenal corticosterone measurements in rats failed to reveal any relationship to "emotionality" as appraised by the response to handling and open field activity.

Treiman, D. M., Fulker, D. W., Levine, S.: "Interaction of genotype and environment as determinants of corticosteroid response to stress." *Dev. Psychobiol.* **3**: 131-140 (1970). G82,877/70

In very young rats, "highly significant and opposing genetic and maternal effects interacted to limit extreme plasma corticosterone

concentrations following stress" (electroshock).

Allen, H. M.: "Gastrointestinal erosions in wild rats subjected to 'social stress.'" *Life Sci. [I]* 11: 351-356 (1972). G90,995/72

Lybeck, H., Leppäläluoto, J., Virkkunen, P.: "The effect of pertinent and non-pertinent stimuli on the secretions of thyrotropin and corticotropin." *Int. J. Neurosci.* 5: 47 (1973).

J19,727/73

ACTH secretion rises under the influence of cold in both the rat and the rabbit, but TTH release remains unchanged in the latter. [If this difference does depend upon the strain of rabbits, then the stressor effect of cold varies from that of fear, since some wild rabbits develop acute hyperthyroidism when chased by a dog (H.S.).]

Alexander, N. "Psychosocial hypertension in members of a Wistar rat colony." *Proc. Soc. Exp. Biol. Med.* 146: 163-169 (1974).

H87,183/74

Various social conditions (particularly aggregation and isolation) can cause hypertension in the rat.

Friedman, R.: "The effect of punishment on the blood pressure of rats with a genetic susceptibility to experimental hypertension," p. 78. Thesis, State University of New York at Stony Brook, 1974. J22,102/74

Hallbäck, M., Folkow, B.: "Cardiovascular responses to acute mental 'stress' in spontaneously hypertensive rats." *Acta Physiol. Scand.* 90: 684-698 (1974). J13,405/74

Genetically hypertensive rats showed more pronounced cardiovascular responses to the stressor effect of sound than did either normotensive controls or renal hypertensive rats of a normal strain. Hence, in his case, hyperreactivity is genetically conditioned.

Barnett, J. L., Cheeseman, P., Cheeseman, J., Douglas, J. M., Phillips, J. G.: "Adrenal responsiveness in ageing Brattleboro rats with hereditary diabetes insipidus." *Age and Ageing* 3: 189-195 (1974). J17,972/74

"Although the resting plasma corticosterone levels were drastically depressed in homozygous DI [diabetes insipidus] rats, there was no impairment of the response to stress; the adrenal glands of homozygous rats were significantly more responsive to stress than the corresponding heterozygous rats."

Wiley, M. K., Pearlmuter, A. F., Miller, R. E.: "Decreased adrenal sensitivity to

ACTH in the vasopressin-deficient (Brattleboro) rat." *Neuroendocrinology* 14: 257-270 (1974).

H88,352/74

In vasopressin-deficient Brattleboro rats, homozygous for diabetes insipidus, plasma corticosterone concentrations during stress (ether, laparotomy) rose much less than in genetically normal controls. That they did respond to some extent confirms that vasopressin is not identical with CRF. In vitro observations suggest that in the vasopressin-deficient strain, the adrenal glands themselves are relatively insensitive to ACTH. The presence of vasopressin in the internal milieu during early life may permanently influence adrenal sensitivity (18 refs.).

Murgas, K., Czako, M., Dobráková, M.: "Participation of 'emotionality' in activation of the adrenal cortex of rats in some stress situations." *Acta Neurobiol. Exp. (Warsz.)* 34: 467-475 (1974).

J15,408/74

Through the use of plasma corticosterone levels as indicators of stress, a relationship was found between the excitability of individual animals and the activity of their adrenal cortex upon exposure to various stressors.

Friedman, R., Dahl, L. K.: "The effect of chronic conflict on the blood pressure of rats with a genetic susceptibility to experimental hypertension." *Psychosom. Med.* (In press).

J24,878/

Rats genetically susceptible to experimental hypertension were exposed to several aversive stimuli. "Despite weekly fluctuations, a pattern emerged wherein subjects exposed to an approach (food)-avoidance (shock) conflict usually exhibited the highest blood pressures followed closely by rats given the same amount of food and shock but independent of their behavior." Usually the blood pressures returned to normal after the stressful experience, but there was "some indication in a few rats that the 'stress-induced' elevations could be maintained for extended periods following removal of the stress."

Sheep. Clegg, M. T., Ganong, W. F.: "The effect of hypothalamic lesions on ovarian function in the ewe." *Endocrinology* 67: 179-186 (1960).

J12,312/60

In ewes, stereotaxic lesions in various parts of the hypothalamus interfered selectively with diverse manifestations of adenohypophyseal activity. In two animals with stalk lesions, peripheral 17-OHCS failed to show a rise after stress (laparotomy), but in none

of the animals was there any significant adenohypophyseal atrophy.

Adams, J. H., Daniel, P. M., Prichard, M. M. L.: "The effect of stalk section on the volume of the pituitary gland of the sheep." *Acta Endocrinol. (Kbh.)* **43** Supp. 81: 1-27 (1963). E25,464/63

In sheep, the pituitary stalk was transected, a plate being inserted between the cut ends to prevent vascular regeneration. Comparatively small areas of the adenohypophysis escaped infarction, and the infundibular process decreased in volume. The location of the infarcted areas was attributed to differential distribution of the stalk vessel.

Bost, J., Dorleac, E.: "Influence de trois types de stimulation sonore sur le taux plasmatique des acides gras non estérifiés (FFA) chez le Mouton" (Effects of three types of auditory stimulation on plasma levels of non-esterified fatty acids in lambs). *C.R. Soc. Biol. (Paris)* **160**: 2340-2343 (1966).

F80,786/66

In lambs, various types of auditory stimulation greatly increased plasma FFA, although adaptation eventually occurred.

Panaretto, B. A., Ferguson, K. A.: "Comparison of the effects of several stressing agents on the adrenal glands of normal and hypophysectomized sheep." *Aust. J. Agric. Res.* **20**: 115-124 (1969). J24,295/69

Adrenocortical hemorrhages are seen in intact, but not in hypophysectomized and ACTH-maintained sheep, following treatment with EP, endotoxin or metyrapone.

Panaretto, B. A., Vickery, M. R.: "The rates of plasma cortisol entry and clearance in sheep before and during their exposure to a cold, wet environment." *J. Endocrinol.* **47**: 273-285 (1970). H28,932/70

In sheep exposed to cold, "decreased cortisol clearance rates did not appear to contribute to the great increases in plasma concentration until rectal temperature was about 34°." Curiously, the adrenal cortex and liver of the sheep were heavily infiltrated with fat after severe hypothermia.

Thwaites, C. J.: "Embryo mortality in the heat stressed ewe. III. The role of the corpus luteum, thyroid and adrenal glands." *J. Reprod. Fertil.* **21**: 95-107 (1970).

H21,604/70

Increased embryo mortality in ewes stressed during pregnancy is ascribed to the G.A.S.

Slee, J.: "Resistance to body cooling in male and female sheep, and the effects of previous exposure to chronic cold, acute cold and repeated short cold shocks." *Anim. Prod.* **12**: 13-21 (1970). J10,493/70

Resistance of shorn female sheep to cold can be greatly increased by a single previous exposure of a few hours. Females are more resistant to cooling than are males. Daily short cold shocks reduced cold resistance and inhibited acclimatization in females, but not in males.

Tollersrud, S., Baustad, B., Flatlandsmo, K.: "Effects of physical stress on serum enzymes and other blood constituents in sheep." *Acta Vet. Scand.* **12**: 220-229 (1971) (Norwegian). J20,894/71

Panaretto, B. A., Vickery, M. R.: "The distribution of cortisol and its rate of turnover in normal and cold-stressed shorn sheep." *J. Endocrinol.* **55**: 519-531 (1972). H64,137/72

Alexander, G., Bell, A. W., Hales, J. R. S.: "The effect of cold exposure on the plasma levels of glucose lactate, free fatty acids and glycerol and on the blood gas and acid-base status in young lambs." *Biol. Neonate* **20**: 9-21 (1972). J7,653/72

"When young lambs were exposed to very cold conditions, but maintained normal body temperature, there were substantial increases in the plasma concentration of glucose, lactic acid, free fatty acids and glycerol; muscle glycogen was depleted by about one third after three quarter h of exposure." Venous blood revealed an acidosis that was aggravated by infusions of EP or NEP.

Purchas, R. W.: "The response of circulating cortisol levels in sheep to various stresses and to reserpine administration." *Aust. J. Biol. Sci.* **26**: 477-489 (1973). J3,638/73

Alexander, D. P., Britton, H. G., Nixon, D. A., Ratcliffe, J. G., Redstone, D.: "Corticotrophin and cortisol concentrations in the plasma of the chronically catheterised sheep fetus." *Biol. Neonate* **23**: 184-192 (1973). J10,051/73

In chronically catheterized sheep fetuses, plasma ACTH levels were unusually elevated. Plasma cortisol was not strictly related to ACTH in individual samples but showed a high correlation in pooled data. The process of catheterization itself may have acted as a stressor.

Panaretto, B. A.: "Relationship of visceral blood flow to cortisol metabolism in cold-stressed sheep." *J. Endocrinol.* **60**: 235-245 (1974). H83,404/74

As long as sheep exposed to cold are capable of maintaining their body temperature, plasma cortisol levels are raised conjointly with cortisol metabolic clearance rates (radio-cortisol). Following continued exposure, when the animals lose their ability to maintain normal rectal temperatures, the plasma cortisol levels rise still further, but the metabolic clearance rates fall significantly below normal. The latter change is ascribed largely to reductions in hepatic and renal blood flow.

Hales, J. R. S., Brown, G. D.: "Net energetic and thermoregulatory efficiency during panting in the sheep." *Comp. Biochem. Physiol. [A]* **49**: 413-422 (1974).

H93,878/74

Clapp, J. F., Patel, N., Abrams, R. M.: "Fetal metabolic response to surgical stress" (abstracted). *Physiologist* **17**: 196 (1974).

H89,878/74

In lamb fetuses, surgical stress causes changes in oxygen and glucose utilization, lactate production and amino acid uptake.

Squirrel. Noble, G. A.: "Stress and parasitism. I. A preliminary investigation of the effects of stress on ground squirrels and their parasites." *Exp. Parasitol.* **11**: 63-67 (1961).

G38,126/61

In ground squirrels (*Citellus armatus*), exposure to various stressors increased susceptibility to infection with protozoa, mostly *Trichomonas*.

Tupaia. Sorenson, M. W., Conaway, C. H.: "Observations of tree shrews in captivity." *Sabah Soc. J.* **2**: 77-91 (1964).

J12,748/64

Sorenson, M. W., Conaway, C. H.: "Observations on the social behavior of tree shrews in captivity." *Folia Primatol.* (Basel) **4**: 124-145 (1966). J11,006/66

General review and personal observations on the effect of captivity upon behavior, particularly stress manifestations, in various tree shrews.

Autrum, H., Holst, D. von: "Sozialer 'Stress' bei Tupajas (*Tupaia glis*) und seine Wirkung auf Wachstum, Körbergewicht und Fortpflanzung" (Social stress in *tupaias* [*Tupaia glis*] and its effect on growth, body

weight and fertility). *Z. Vergl. Physiol.* **58**: 347-355 (1968). G58,325/68

Description of the autonomic nervous responses characteristic of social stress in the tree shrew.

Holst, D. von: "Sozialer Stress bei Tupajas (*Tupaia belangeri*). Die Aktivierung des sympathischen Nervensystems und ihre Beziehung zu hormonal ausgelösten ethologischen und physiologischen Veränderungen" (Social stress in *Tupaia* [*Tupaia belangeri*]. Activation of the sympathetic nervous system and its relation to hormonal stimulated ethologic and physiologic changes). *Z. Vergl. Physiol.* **63**: 1-58 (1969). G90,282/69

The hairs on the tail of the tree shrew normally lie flat, but they become erect and bushy at the slightest stimulation and thus act as a readily appraisable indicator of sympathetic activity. This response is elicited especially by other members of the species through sexual excitation or aggression. On the basis of studies on the mechanism of this reaction, "an attempt to interpret the results according to Selye's 'general adaptation syndrome' is made" (several hundred refs.).

Holst, D. von: "Renal failure as the cause of death in *Tupaia belangeri* exposed to persistent social stress." *J. Comp. Physiol.* **78**: 236-273 (1972). G93,301/72

When two adult male *Tupaia* are introduced, they immediately begin to fight. Subsequently, merely seeing the victor induces stress manifestations in the defeated *Tupaia*. This is associated with a constant decline in body weight, liver glycogen, blood hemoglobin and kidney weight, eventually resulting in fatal uremia. "The evidence from natural populations, when examined along with the findings from tree-shrews, show the great significance which social stress may have in the origin of renal disease—possibly in man as well as in animals."

Holst, D. von: "Die Funktion der Nebennieren männlicher *Tupaia belangeri*. Nebennierengewicht, Ascorbinsäure und Glucocorticoide im Blut bei kurzem und andauerndem soziopsychischem Stress" (The function of the adrenals in male *Tupaia belangeri*. Adrenal weight, ascorbic acid and glucocorticoids in the blood after acute and prolonged psychosocial stress). *J. Comp. Physiol.* **78**: 289-306 (1972). G93,303/72

Male *Tupaia*, after being defeated by a trained fighter, were separated from him by a wire mesh so that they could continually

see the victor without being attacked. The fight was repeated every one or two days. Under these conditions, the defeated *Tupaia* died in less than twenty days owing to the "psychosocial stress" associated with adrenal enlargement and increased ascorbic acid concentration. Plasma glucocorticoid levels initially dropped and then rose above normal. An elevation of adrenal ascorbic acid also occurred in *Tupaia* exposed to various other stressors, in contrast to the characteristic depletion in most other species.

D'Souza, F., Martin, R. D.: "Maternal behaviour and the effects of stress in tree shrews." *Nature* **251**: 309-311 (1974).

J23,295/74

In tree shrews, the noise of a fire bell accelerates the suckling rhythm but decreases the quantity of milk given over a forty-eight hour period. More severe stress causes cannibalism.

Vole. Clarke, J. R.: "The effect of fighting on the adrenals, thymus and spleen of the vole (*Microtus agrestis*)."
J. Endocrinol. **9**: 114-126 (1953). B77,639/53

Voles kept in a cage viciously attack any strangers of the same species introduced among them. The fighting results in adrenal enlargement and thymic atrophy characteristic of the alarm reaction, but instead of the usual splenic atrophy there is enlargement of the spleen, perhaps because of secondary infection.

Roth, R. R.: "The effect of temperature and light combinations upon the gonads of male red-back voles."
Biol. Reprod. **10**: 309-314 (1974).

J12,665/74

Various Mammals. Scharrer, E., Scharrer, B.: "Secretory cells within the hypothalamus."
Res. Public Assoc. Nerv. Ment. Dis. **20**: 170-194 (1940). 78,342/40

Excellent and well illustrated review on secretory neurons in the hypothalamus of various vertebrates.

Elton, R. L., Zarrow, I. G., Zarrow, M. X.: "Depletion of adrenal ascorbic acid and cholesterol: a comparative study."
Endocrinology **65**: 152-157 (1959). C71,402/59

"Exposure to severe cold produced significant depression of adrenal ascorbic acid in opossums and dogs, but failed to do so in frogs, toads, chickens, mice, hamsters, rabbits, and cats. ACTH failed to produce such a depletion in frogs, toads, chickens, rab-

bits, cats, or dogs; significant depressions were observed in opossums, mice and hamsters. Adrenal cholesterol concentrations remained unchanged in most species tested; however, increases were observed in rabbits following cold exposure, and in frogs, following ACTH treatment" (24 refs.).

Brodie, D. A., Hanson, H. M.: "A study of the factors involved in the production of gastric ulcers by the restraint technique."
Gastroenterology **38**: 353-360 (1960).

C87,271/60

Mice, rats, guinea pigs and hamsters exhibited a high incidence of gastric ulcers following restraint, whereas rabbits and monkeys were much more resistant. Fasting predisposed rats to this type of stress ulcer. Young rats proved to be more susceptible than old. Hypophysectomy and bilateral sub-diaphragmatic vagotomy did not significantly reduce the incidence of restraint ulcers, whereas bilateral adrenalectomy significantly increased it.

Christian, J. J.: "Phenomena associated with population density."
Proc. Natl. Acad. Sci. U.S.A. **47**: 428-449 (1961).

D79,921/61

Crowding produces typical manifestations of the G.A.S. in a variety of species, including *Mus*, *Rattus*, *Microtus*, *Clethrionomys*, *Marmota*, *Oryctolagus*, *Lepus*, *Sylvilagus*, *Cervus*, *Myocastor*, dog, guinea pig, monkey and man. The diminution in gonadotropic hormone production associated with the increased ACTH secretion characteristic of stress is an important factor in regulating population density (73 refs.).

Christian, J. J.: "The pathology of overpopulation."
Milit. Med. **128**: 571-603 (1963).

E22,467/63

A review of the literature on the effects of overpopulation in various species. In the mouse, woodchuck (*Marmota monax*) and Japanese deer (*Cervus nippon*), increased population density elicits structural and functional adrenal hyperactivity which—depending upon the species—is associated with decreased fertility, aggressiveness or renal glomerular disease.

Simoes, J.: *Stress nos Animais de Laboratorio* (Stress in laboratory animals), p. 43. Bahia, Brazil: Rockefeller Found. e Fund. Desenv. Cienc., 1963 (Portuguese).

G21,915/63

Monograph on the effect of stress upon

various experimental animals, especially under laboratory conditions (73 refs.).

Duvernoy, H., Koritke, J. G.: "Les vaisseaux sous-épendymaires du recessus hypophysaire" (Subependymal vessels of the hypophyseal recess). *J. Hirnforsch.* **10**: 227-245 (1968). J12,676/68

Extensive histologic studies on the subependymal origins of the hypothalamo-adenohypophyseal portal vessels in *various mammals* and *birds*. There exist numerous connections between the subependymal vessels and the cavity of the third ventricle, from which they are separated only by a thin and often discontinuous ependymal membrane. "Such a structure will possibly allow exchanges between the blood of the hypophysis and the ventricular liquid which is continuously in motion in the third ventricle."

Johke, T.: "Factors affecting the plasma prolactin level in the cow and the goat as determined by radioimmunoassay." *Endocrinol. Jap.* **17**: 393-401 (1970).

H39,458/70

Radioimmunologic determinations in *cows* and *goats* led to the conclusion that various stressors (venipuncture, pain, restraint, emotional disturbances) elevate the plasma LTH level, but milking is most effective in eliciting this response.

Augee, M. L., McDonald, I. R.: "Role of the adrenal cortex in the adaptation of the monotreme *Tachyglossus aculeatus* to low environmental temperature." *J. Endocrinol.* **58**: 513-523 (1973). H77,116/73

Various investigations suggest that although adrenocortical function has not developed very well in *monotremes* (the lowest order of mammals), their adrenocortical secretions are indispensable for resistance to cold. "The metabolic defect in adrenalectomized echidnas appears to be a failure of adequate mobilization of energy reserves to sustain increased metabolic heat production through muscular activity. In both intact and adrenalectomized echidnas the major factor leading to torpor was a fall in plasma glucose concentration." Adrenal hypertrophy in intact echidnas stressed by fasting or cold also shows the importance of these glands for resistance.

Birds. Siegel, H. S.: "The relation between crowding and weight of adrenal glands in

chickens." *Ecology* **40**: 495-498 (1959). J10,863/59

In laying *chickens*, crowding increases adrenal weight, although pituitary and thyroid weights remain unaffected.

Siegel, H. S.: "Egg production characteristics and adrenal function in White Leghorns confined at different floor space levels." *Poultry Sci.* **38**: 893-898 (1959).

J10,896/59

Crowding definitely diminished egg production in *chickens*. Although this was usually accompanied by adrenal hypertrophy, the two changes did not run strictly parallel. Presumably both were due to stress.

Brown, K. I.: "'Stress' and its implications in *poultry* production." *World Poultry Sci. J.* **15**: 255-263 (1959). D96,230/59

Sturkie, P. D., Textor, K.: "Relationship of blood pressure levels in *chickens* to resistance to physical stresses." *Am. J. Physiol.* **200**: 1155-1156 (1961). D10,931/61

Miller, R. A.: "Hypertrophic adrenals and their response to stress after lesions in the median eminence of totally hypophysectomized pigeons." *Acta Endocrinol. (Kbh.)* **37**: 565-576 (1961). D80,692/61

In *pigeons*, hypophysectomy causes adrenal atrophy but the interrenal tissue becomes hypertrophic during stress elicited by formaldehyde or insulin, even in the absence of the pituitary. Very large lesions in the ME and ventral hypothalamus produce adrenal hypertrophy rather than atrophy, even after total hypophysectomy. The suprarenals also react to formaldehyde. "It appears that the interrenal tissue of the pigeon responds to a humoral stimulus not of hypophyseal origin in the absence of the hypophyseal-hypothalamic system."

Brown, K. I.: "The validity of using plasma corticosterone as a measure of stress in the turkey." *Proc. Soc. Exp. Biol. Med.* **107**: 538-542 (1961). D20,460/61

In *turkeys*, the main free corticosteroid found in the plasma is corticosterone. Its concentration increases under the influence of ACTH and various stressors (water deprivation, cold). Hypophysectomy does not significantly alter the resting plasma corticosterone level, but prevents its rise under stress. Presumably, plasma corticosterone is a valid indicator of stress in these birds, although the adrenals are relatively autonomous in that their basic corticoid production

continues in the absence of the anterior pituitary.

Thompson, W. R., O'Kieffe, M. W.: "Imprinting: its effect on the response to stress in chicks." *Science* **135**: 918-919 (1962).

D21,133/62

Young *chicks* imprinted to surrogate mothers showed increased resistance to the stress of exposure to a doorbell (as judged by their activity level), both in the presence and in the absence of their surrogate mothers. No such difference was seen upon exposure to the more severe stress of total food and water deprivation.

Donoso, A. O.: "Concentration de l'adrénaline et de la noradrénaline dans le plasma de quelques espèces d'oiseaux. Action de divers facteurs" (Adrenaline and noradrenaline concentrations in the plasma of *various species of bird*. The effect of diverse factors). *C. R. Soc. Biol. (Paris)* **156**: 790-795 (1962).

Study on stress and adaptation in *chickens*.

Kendler, J., Harry, E. G.: "Systemic *Escherichia coli* infection as a physiological stress in chickens." *Res. Vet. Sci.* **8**: 212-218 (1967).

J23,505/67

In *chickens*, *coli*-septicemia caused a characteristic stress syndrome with involution of the spleen and bursa, associated with increased bursal β -glucuronidase.

Freeman, B. M.: "Effect of stress on the ascorbic acid content of the adrenal gland of *Gallus domesticus*." *Comp. Biochem. Physiol.* **23**: 303-305 (1967).

F90,188/67

In young *chickens*, adrenal ascorbic acid is depleted within ten minutes of handling. However, this decrease is only of a very short duration and has therefore been missed by many previous investigators (14 refs.).

Miller, R. A.: "Regional responses of interrenal tissue and of chromaffin tissue to hypophysectomy and stress in pigeons." *Acta Endocrinol. (Kbh.)* **55**: 108-118 (1967).

F79,962/67

In *pigeons*, the cortical and medullary cells of the adrenals are intermixed and hence three distinct cortical zones such as are seen in mammals cannot be distinguished. Yet there is some evidence that certain regions

of the avian interrenal tissue may be homologous with the mammalian cortical zones. Hypophysectomy causes only a slight decrease in the weight of the pigeon adrenal, due mainly to atrophy of interrenal (cortical) cells near the center of the gland. Stress (repeated injections of formalin when they are on a low sodium diet) elicits hypertrophy and hyperplasia of both interrenal and chromaffin tissue, even in hypophysectomized pigeons.

Thaxton, P., Sadler, C. R., Glick, B.: "Immune response of chickens following heat exposure or injections with ACTH." *Poultry Sci.* **47**: 264-266 (1968). G58,548/68

In *chickens* exposed to heat, treatment with ACTH or cortisone before antigen injection depresses the antibody response to sheep red blood cells. Such treatment also inhibits the development of the bursa of Fabricius and the spleen. This "might be explained by an interference with phagocytosis or immunoglobulin producing cells brought about by direct effect of the treatment or by some humoral substance like corticosterone."

Burton, R. R., Smith, A. H.: "Criteria for physiological stress produced by increased chronic acceleration." *Proc. Soc. Exp. Biol. Med.* **128**: 608-611 (1968). H2,172/68

"Physiological fitness relative to exercise capacity, sexual development, and survival of an individual with respect to a stressful environment, increased chronic acceleration, may be quantitatively determined in the *chicken* by hematological methods."

Sturkie, P. D., Poorvin, D., Ossorio, N.: Levels of epinephrine and norepinephrine in blood and tissues of duck, pigeon, turkey, and chicken." *Proc. Soc. Exp. Biol. Med.* **135**: 267-270 (1970). H32,255/70

In *ducks*, *pigeons*, *turkeys* and *chickens*, the plasma concentration of EP is considerably higher than that of NEP. The effect of excitement (handling) or lack of it (pentobarbital sedation) on plasma and tissue catecholamines is also reported. [The few super-

ficially described experiments do not lend themselves to interpretation (H.S.).]

Lawzewitsch, I. von, Sarrat, R.: "Das neurosekretorische Zwischenhirn-Hypophysensystem von Vögeln nach langer osmotischer Belastung" (The neurosecretory hypothalamo-hypophyseal system of birds after long-term osmotic stress). *Acta Anat. (Basel)* **77**: 521-539 (1970). G84,461/70

It is concluded that "the hypothalamo-hypophyseal neurosecretory system of *cocks* under a chronic stress of a 0.3 m NaCl solution ad libitum, resulting in an exhaustion of the system, enters into a period of adaptation during which new neurosecretory material is stored by the cells of the nucleus. This adaptation could either result from the synthesizing ability of the neurosecretory cells being increased by a prolonged stress or from the decrease in hormonal demand due to functional changes in the periphery."

Bhattacharyya, T. K., Ghosh, A.: "Influence of surgical and steroid bursectomy on the behavior of adrenal ascorbic acid during stress in juvenile pigeons." *Gen. Comp. Endocrinol.* **15**: 420-424 (1970).

H35,126/70

In juvenile *pigeons*, bursectomy facilitated the depletion of adrenal ascorbic acid during stress (formalin). Cortisol caused involution of the bursa but left adrenal ascorbic acid levels unaltered after exposure to stress.

Palokangas, R., Hissa, R.: "Thermoregulation in young black-headed gull (*Larus ridibundus L.*)" *Comp. Biochem. Physiol. [A]* **38**: 743-750 (1971). H36,410/71

Exposure of the *black-headed gull* to cold slightly elevates plasma corticosterone and NEP concentrations, whereas it significantly decreases EP content.

Siegel, H. S.: "Adrenals, stress and the environment." *World Poultry Sci. J.* **27**: 327-349 (1971). G87,043/71

A review of the literature suggests that in birds the hypothalamus is the source of an extrahypophyseal, ACTH-like polypeptide. "In any case, the adrenal glands of birds do respond directly to ACTH by hypertrophy and increased secretion of corticosteroids. Although various environmental stimuli produce evidence of a 'stress response' in birds, it is often necessary that several criteria of response be evaluated because specific responses to a particular stimulus may contradict or mask a single response." A period of apparent refractoriness to ACTH occurs in young birds, perhaps as a consequence of low reserve in steroid precursors (about 70 refs.).

Bhattacharyya, T. K., Ghosh, A.: "Cellular modification of interrenal tissue induced by corticoid therapy and stress in three avian species." *Am. J. Anat.* **133**: 483-493 (1972). G89,788/72

In three avian species (*quail, parakeet* and *myna*), dexamethasone caused atrophy of the cortical elements in the interrenal tissue, in which cortical and medullary cells are intermixed. However, zonal differences in the compensatory atrophy of the cortical cells were not detectable. "Following exposure to acute formalin stress at the termination of chronic corticoid therapy, the interrenal tissue regularly responded by hypertrophy in all three types of birds." The prompt response of the atrophic interrenal gland to stress also suggests that the hypothalamo-hypophyseal regulation of the adrenal is different from that in mammals (23 refs.).

Péczely, P.: "Effect of ether stress on CRF-ACTH system of the domestic *pigeon*." *Acta Biol. Acad. Sci. Hung.* **23**: 23-29 (1972). G99,695/72

"In 15 min after the stress, the CRF activity and the ACTH content of the pituitary gland decreased by 17 and 55 per cent, respectively, and the corticosterone produc-

tion of the adrenals increased by 218 per cent."

Smith, R. M.: "Circulation, respiratory volumes and temperature regulation of the pigeon in dry and humid heat." *Comp. Biochem. Physiol. [A]* **43**: 477-490 (1972).

H60,824/72

Description of respiratory and cardiovascular changes allegedly characteristic of stress in *pigeons* exposed to humid heat.

Rhees, R. W., Abel, J. H. Jr., Frame, J. R.: "Effect of osmotic stress and hormone therapy on the hypothalamus of the *duck* (*Anas platyrhynchos*)." *Neuroendocrinology* **10**: 1-22 (1972).

H58,144/72

Bouillé, C., Herbuté, S., Baylé, J. D.: "Modulatory influences of central nervous structures on pituitary-adrenocortical activity: effect of chronic deafferentation of the hypothalamus in the pigeon." *J. Physiol. (Paris)* **66**: 437-446 (1973). J9,213/73

In Carneau *pigeons*, deafferentation of the hypothalamus with a modified Halász knife suppressed the usual circadian variations in plasma corticosterone levels. Responses to ether stress were reduced but not abolished.

Abati, A. L., McGrath, J. J.: "Physiological responses to acute hypoxia in altitude-acclimatized *chickens*." *J. Appl. Physiol.* **34**: 804-808 (1973) (32 refs.). H81,614/73

Wise, P. M., Frye, B. E.: "Functional development of the hypothalamo-hypophyseoadrenal cortex axis in the chick embryo, *Gallus domesticus*." *J. Exp. Zool.* **185**: 277-291 (1973). J7,865/73

Studies on *chick* embryos, based mainly on plasma corticosterone determinations after stress produced by opening the shell and breaking one shank. "The adrenal exhibits significant autonomous functional capability prior to day 14, and the pituitary becomes important in maintaining both the resting level of hormone and the stress response between days 14 and 16 of incubation. The hypothalamus does not appear to control normal resting levels of corticosterone, but is essential for the stress response." The initial autonomy of the adrenal is demon-

strated by the persistence of significant plasma corticosterone levels after decapitation of the embryo.

Halawani, M. E. el, Waibel, P. E., Appel, J. R., Good, A. L.: "Effects of temperature stress on catecholamines and corticosterone of male turkeys." *Am. J. Physiol.* **224**: 384-388 (1973). H65,841/73

In male *turkeys*, neither heat nor stress had any pronounced effect upon adrenal, brain or heart catecholamine concentrations; however, plasma corticosterone levels rose. When α -MT (an inhibitor of catecholamine biosynthesis) was given prior to stress exposure, catecholamine concentrations fell markedly, unless the birds had previously been adapted to hot or cold environments. "These findings indicate that an increased rate of catecholamine and corticosterone release seems to be required during the initial response to temperature stress, and may be associated with the adaptive changes leading to temperature acclimation" (20 refs.).

Bouillé, C., Baylé, J. D.: "Experimental studies on the adrenocorticotrophic area in the pigeon hypothalamus." *Neuroendocrinology* **11**: 73-91 (1973). H66,001/73

In *pigeons*, hypothalamic control of stress-induced adrenocortical activity was examined by means of hypothalamic lesions combined with hypophysectomy or pituitary autografts. "A well-defined adrenocorticotrophic area is present in the posterior medial and lateral hypothalamic region. Destruction of the area leads to the same decrease of the plasma corticosterone level as is seen after adeno-hypophysectomy and also prevents the progressive recovery of adrenocortical function after autografting. The adrenal cortical response to various stressful stimuli is suppressed after lesioning of this same area." It remains to be seen whether the residual adrenocortical responsiveness of hypophysectomized pigeons is due to partial autonomy of the gland or to some extrahypophyseal control system. In any case, corticotrophic activity is abolished by destruction of the regulating hypothalamic area and hence the hypothesis of the functional autonomy of the pigeon adrenal "is invalidated."

Holmes, P. W., Smith, B. L.: "Ethanol consumption by pigeons under stress." *Q. J. Stud. Alcohol* **34**: 764-768 (1973).

J21,557/73

Pigeons chronically exposed to repeated electroshocks voluntarily drank solutions of 1 to 4 percent ethanol in preference to water.

Mitchell, B. W., Siegel, H. S.: "Physiological response of *chickens* to heat stress measured by radio telemetry." *Poultry Sci.* **52**: 1111-1119 (1973). J22,022/73

Nvota, J., Lamošová, D., Fáberová, A.: "Critical periods in the development of chicks." *Physiol. Bohemoslov.* **22**: 337-343 (1973).

J21,555/73

The stress of restraint during a critical period of about three to four weeks after hatching produced a maximal decrease in thyroid activity in adulthood and a significant drop in the BMR of the *chick*. "The critical phase for regulation of the function of the pituitary-adrenal and pituitary-gonad axis was found to be the period between the 15th and 21st day after hatching. Exposure to stress in this phase caused a significantly greater reaction of the adrenals to stress situations in the adult hens and significantly stimulated sexual maturation (egg-laying)."

Duncan, I. J. H.: "The behaviour of the domestic fowl in stressful situations." *Br. Vet. J.* **130**: 89-90 (1974). J20,870/74

Howard, B. R.: "The assessment of stress in *poultry*." *Br. Vet. J.* **130**: 88-89 (1974). J20,868/74

Baylé, J. D., Bouillé, C.: "Activité corticosurrénalienne après lésion de l'hippocampe chez le pigeon" (The adrenal cortex function after lesion of the hippocampus in the pigeon). *Gen. Comp. Endocrinol.* **22**: 360-361 (1974). H83,189/74

Bilateral electrolytic lesions in the hippocampus in *pigeons* raise the basic plasma corticosterone level. The response to immobilization stress is only slightly reduced. Conversely, stimulation of the hippocampus diminishes plasma corticosterone.

Péczely, P., Szokoly, P. M.: "The effect of acute and chronic stimulation on ACTH cell of the pigeon's adenohypophysis." *Gen. Comp. Endocrinol.* **22**: 367 (1974).

H83,210/74

In pigeons, acute insulin hypoglycemia and fourteen-day treatment with metyrapone were studied in connection with their effect upon the epsilon cells (which were stained light red by Herland's stain). "Insulin stress causes a strong hypertrophy of the ACTH cells. The endoplasmic reticulum shows an extreme hyperplasia, and the quantity of the secretion granules and the ACTH content of the pars distalis decrease. Metyrapone treatment causes hypertrophy and hyperplasia of the ACTH cells. The quantity of the endoplasmic reticulum increases; the cisternae are dilated, and they form vesicles. A great number of secretory granules appear, mainly on the periphery of the cells. The ACTH content of the pars distalis increases." These findings are in accordance with the assumption that the epsilon cells of birds are the source of ACTH, and that acute and chronic stimulation leads to different EM changes.

Brown, K. I., Nestor, K. E.: "Implications of selection for high and low adrenal response to stress." *Poultry Sci.* **53**: 1297-1306 (1974).

J21,587/74

Turkey lines were selected for high and low adrenal reactions to stress (heat). "Elevated plasma corticosterone in response to stress will probably induce elevated plasma catecholamines. This combination may result in hyperactivity, higher blood pressure, poorer feed efficiency, and poorer reproductive performance. The converse would be true of low adrenal response."

Gross, W. B.: "Stressor effects of initial bacterial exposure of chickens as determined by subsequent challenge exposures." *Am. J. Vet. Res.* **35**: 1225-1228 (1974).

J23,893/74

Chickens bred for a low concentration of plasma corticosterone "inoculated initially with live or killed *Escherichia coli* had increased resistance to *E. coli*, lessened resistance to *Mycoplasma gallisepticum*, and reduced capability to produce antibody." Chickens selected for a high corticosterone concentration were less responsive to the initial inoculation. Metyrapone blocked the resistance induced by the exposure to *E. coli*.

Nestor, K. E., Brown, K. I., Renner,

P. A.: "Effect of genetic changes in egg production, growth rate, semen yield and response to cold stress on early mortality of turkey poulets." *Poultry Sci.* **53**: 204-210 (1974).

Groscolas, R.: "Effet d'une exposition à la chaleur sur la température corporelle et quelques paramètres hématologiques du manchot empereur, *Aptenodytes forsteri*" (Effect of heat exposure on body temperature and hematology in the emperor penguin, *Aptenodytes forsteri*). *Comp. Biochem. Physiol. [A]* **50**: 533-543 (1975).

H98,407/75

Reptiles. Miller, M. R.: "The normal histology and experimental alteration of the adrenal of the viviparous lizard, *Xantusia vigilis*." *Anat. Rec.* **113**: 309-323 (1952).

B36,730/52

In the viviparous Yucca night lizard, as in other lacertilians, the adrenals consist of dorsal medullary and ventral interrenal portions. Hypophysectomy, cortisone and DOC cause lipid depletion and involution of the interrenal cells. ACTH likewise depletes them of lipids but induces hypertrophy and, in large doses, even degenerative changes. Similar alterations indicative of hyperactivity are obtained by the stress of starvation.

Daly, O. W., Davis, G., Siegel, S. M.: "General and comparative biology of experimental atmospheres and other stress conditions: experiments with the turtle, *Pseudemys scripta elegans*." *Aerosp. Med.* **36**: 363-368 (1965).

G28,211/65

Turtles "showed an ability to adapt to a range of atmospheres varying from anaerobic to those containing 100 per cent oxygen, to high and low atmospheric pressures, ultraviolet radiation and reduced temperatures. Such adaptability makes the turtle an excellent specimen for stress experimentation."

Algauhari, A. E. I.: "Experimental studies on the blood sugar in reptiles. Effect of fasting, temperature and insulin administration in *Psammophis sibilans*." *Z. Vergl. Physiol.* **54**: 395-399 (1967).

G45,974/67

In the snake *Psammophis sibilans* the blood sugar is remarkably constant, and fasting up to five months as well as extreme temperature variations fail to alter it. However, this snake is also very (though not completely) resistant to insulin hypoglycemia, and it is questionable whether the constant level of its blood sugar upon exposure to

otherwise active stressors really does indicate resistance to stress as such.

Spigel, I. M., Ramsay, A.: "Excretory electrolytes and response to stress in a reptile." *J. Comp. Physiol. Psychol.* **68**: 18-21 (1969). G67,129/69

"Elevated urinary alkali metal (combined Na^+ and K^+) was observed in electrically shocked turtles."

Banerjee, S. K.: "Histochemical studies on the neurosecretory system of the common garden lizard *Calotes versicolor* (Daudin) under experimental condition." *Histochemie* **23**: 59-62 (1970). J21,402/70

Gist, D. H.: "Effects of mammalian ACTH on liver and muscle glycogen levels in the South American caiman (Caiman sclerops)." *Gen. Comp. Endocrinol.* **19**: 1-6 (1972).

H58,201/72

In the South American *caiman*, liver and muscle glycogen concentrations were not affected even after twenty days of starvation, but relative hepatic weight decreased. ACTH augmented the liver glycogen in July and October, but not in February or May. Apparently, the pituitary-adrenal axis is operative in reptiles.

Webb, G. J. W., Johnson, C. R.: "Head-body temperature differences in turtles." *Comp. Biochem. Physiol. [A]* **43**: 593-611 (1972). H60,828/72

Extensive review and personal observations on temperature regulation in *turtles* exposed to "heat stress." [No special studies have been made of the characteristic stress effects (H.S.).]

Deparis, P.: "Modifications hématologiques provoquées par la manipulation et la saignée chez *Pleurodeles waltl* Michah (Amphibien, Urodèle)" (Hematologic modifications induced by manipulation and bleeding in *Pleurodeles waltl* Michah [Amphibian, Urodele]). *J. Physiol.* (Paris) **64**: 19-30 (1972). G91,179/72

In the *newt Pleurodeles*, hemorrhage causes pronounced neutrophilia followed within a few hours by lymphopenia and eosinopenia. The same results are obtained by other stressors, even by mere manipulation of the animals. These hematologic variations are ascribed to stress under the influence of corticoids.

Funkhouser, D., Goldstein, L.: "Urea response to pure osmotic stress in the aquatic toad *Xenopus laevis*."*Am. J. Physiol.* **224**: 524-529 (1973). H67,004/73

Juráni, M., Murgaš, K., Mikulaj, L., Babušková, F.: "Effect of stress and environmental temperature on adrenal function in *Rana esculenta*."*J. Endocrinol.* **57**: 385-391 (1973). H71,773/73

Gona, A. G., Gona, O.: "Prolactin-releasing effects of centrally-acting drugs in the red-spotted *newt*."*Neuroendocrinology* **14**: 365-368 (1974). H89,271/74

Turney, L. D., Hutchison, V. H.: "Metabolic scope, oxygen debt and the diurnal oxygen consumption cycle of the *leopard frog*,

Rana pipiens."*Comp. Biochem. Physiol. [A]* **49**: 583-601 (1974). H93,883/74

Juráni, M., Mikulaj, L.: "The effect of repeated stress upon the reaction of interrenal tissue in frogs and hens."*Gen. Comp. Endocrinol.* **22**: 401 (1974). H83,309/74

In frogs (*Rana ridibunda*) and hens (*Gallos domesticus*), brief immobilization causes hyperactivity of the interrenal tissue, as indicated by increased plasma corticosterone levels and excess synthesis of corticoids by adrenal homogenates. This response is more pronounced after the first than after subsequent immobilizations.

Fish. Merrick, A. W.: "Cardiac glycogen following fulminating anoxia."*Am. J. Physiol.* **176**: 83-85 (1954). G62,149/54

In the *goldfish*, the cardiac glycogen stores are extremely high and difficult to exhaust, even by fulminating anoxia. "Cardiac glycogen is an emergency stand-by used by the heart during periods of anoxic stress." However, complete removal of cardiac glycogen is not necessary for the induction of cardiovascular and respiratory failure, and the observations do not prove any particular resistance of this fish to other stressors.

Mahon, E. F., Hoar, W. S., Tabata, S.: "Histophysiological studies of the adrenal tissues of the goldfish."*Can. J. Zool.* **40**: 449-464 (1962). D58,580/62

The distribution of chromaffin (medullary) and interrenal (cortical) tissues is variable in fish. In some, they are completely separated; in others, they approach the condition in higher vertebrates. In the *goldfish* (*Carassius auratus*), they are closely intermixed. ACTH did not modify the granulation of the interrenal cells, but caused condensation of their cytoplasm with predominance of the "type I" nuclei, as well as alterations in the chromaffin cells. "High temperature produced an exhaustion of large areas of the interrenal cells and alterations in the chrome cells. It is suggested that sudden heat exposure leads to release of secretions and that death occurs before the cells can make an adaptive response. On the other hand, the picture associated with chilling was less extreme and more variable and, in this case, it is probable that the more slowly acting low temperature permits time for considerable cell activation" (36 refs.).

Ball, J. N., Slicher, A. M.: "Influence of hypophysectomy and of an adrenocortical in-

hibitor (SU-4885) on the stress-response of the white blood cells in the teleost fish, *Mollieenesia latipinna Le Sueur*." *Nature* **196**: 1331-1332 (1962). D50,507/62

(*Salmo gairdnerii*) at successive stages in the sexual cycle." *Endocrinology* **78**: 791-800 (1966). F63,818/66

Fontaine, M., Mazeaud, M., Mazeaud, F.: "L'adrénalinémie du *Salmo* *salar* L. à quelques étapes de son cycle vital et de ses migrations" (Adrenalinemia in the *Salmo* *salar* L. during some stages of its vital cycle and its migrations). *C.R. Acad. Sci. (Paris)* **256**: 4562-4565 (1963). J10,785/63

In the *Pacific salmon*, plasma 17-OHCS concentrations rose at various phases of migration upstream during the spawning season, as well as after bleeding, confinement in a tank or injection of ACTH. Spawning steelhead trout showed an even higher rise in plasma corticoids after ACTH injection than did spawning salmon.

In the *salmon* the blood EP content rises during migration to its spawning grounds. This coincides with the previously demonstrated increase in the activity of the interrenal body and in blood corticoid concentrations.

Slicher, A. M., Pickford, G. E., Pang, P. K. T.: "Effects of 'training' and of volume and composition of the injection fluid on stress-induced leukopenia in the *mummichog*." *Progr. Fish-Culturist* **28**: 216-219 (1966). G47,904/66

Mazeaud, M.: "Influence de divers facteurs sur l'adrénalinémie et la noradrénalinémie de la carpe" (Influence of different factors on blood adrenaline and noradrenaline in the carp). *C.R. Soc. Biol. (Paris)* **158**: 2018-2021 (1964). F36,962/64

Comparative studies on the stressor effects particularly the leukopenia produced by several agents in the *mummichog* (*Fundulus heteroclitus*). Earlier literature on the actions of hypophysectomy, ACTH and various stressors upon other fish is briefly reviewed.

In the *carp*, muscular activity and hypoxia cause a slight increase in the EP and a marked rise in the NEP content of the blood. The latter values also rise considerably after hemorrhage and trauma.

Rasmussen, R. A., Rasmussen, L. E.: "Some observations on the protein and enzyme levels and fractions in normal and stressed elasmobranchs." *Trans. N.Y. Acad. Sci.* **29**: 397-413 (1967). J10,798/67

Thomson, D. A.: "Ostracitoxin: an ichthyotoxic stress secretion of the boxfish, *Ostracion lentiginosus*." *Science* **146**: 244-245 (1964). F21,880/64

In various *elasmobranchs*, stressors (muscular fatigue, hypoxia, confinement, osmotic and temperature shock) produced serum and brain enzyme changes interpreted as characteristic of stress.

Under conditions of stress, the *boxfish* exudes a nonprotein hemolytic poison designated "ostracitoxin." Introduction of a newly captured, highly excited specimen into an aquarium can cause the death of all other fish within a few minutes. Partial purification of the toxin suggests that it may be a steroid saponin. It is poisonous also for vertebrates. [Its possible relationship to pheromones is not mentioned (H.S.).]

Stabrowskii, E. M.: "The distribution of adrenaline and noradrenaline in the organs of the baltic lamprey *Lampetra fluviatilis* at rest and under various functional stress." *Zh. Evol. Biokhim. Fiziol.* **3** No. 3: 216-221 (1967). J11,822/67

Fleming, W. R., Pasley, J. N.: "Effect of cold shock, disease, and mammalian corticoids on the spleen of *Lepomis macchirus*." *Proc. Soc. Exp. Biol. Med.* **120**: 196-199 (1965). F53,560/65

In the *lamprey*, chromaffin cells containing EP and NEP are found in various organs, but particularly in the heart. The stress of hypoxia diminishes the EP level in the heart, skeletal muscles and liver, whereas the NEP content increases in liver tissue. "It is suggested that the chromaffin tissue of the lamprey heart acts as the medulla of mammalian suprarenals."

In the *blue-gill fish*, cortisol causes splenic hypertrophy. DOC and various stressors induce atrophy with pigment deposition in the spleen.

Todd, W. R., Laastuen, L. E., Thomas, A. E.: "Effect of amino acid imbalance on liver glycogen levels in young salmon." *Comp. Biochem. Physiol.* **23**: 431-435 (1967). F92,686/67

Hane, S., Robertson, O. H., Wexler, B. C., Krupp, M. A.: "Adrenocortical response to stress and ACTH in Pacific salmon (*Oncorhynchus tshawytscha*) and steelhead trout

In the *chinook salmon* (*Oncorhynchus tshawytscha*), stress was induced by a special device that forced them to swim strongly

against a current until they became exhausted and were swept through an electrical field into an outlet. This stress was associated with a drop in liver glycogen that could be counteracted by a glycine-containing diet whose effect was in turn blocked by concurrent feeding with tyrosine.

Fagerlund, U. H. M.: "Plasma cortisol concentration in relation to stress in adult sockeye salmon during the freshwater stage of their life cycle." *Gen. Comp. Endocrinol.* **8**: 197-207 (1967). F83,321/67

In *salmon*, various forms of stress (handling, physical exercise, disease) greatly increase plasma cortisol concentrations.

Hill, C. W., Fromm, P. O.: "Response of the interrenal gland of rainbow trout (*Salmo gairdneri*) to stress." *Gen. Comp. Endocrinol.* **11**: 69-77 (1968). H2,458/68

Although very intense acute stressors raise plasma cortisol in the rainbow trout, the effect of chronic low-level stress is transitory in this respect. Plasma cortisol concentrations "do not appear to be a useful indicator of the existence of chronic stressful conditions."

Yamashita, H.: "Haematological study of a species of *rockfish*, *Sebasticus marmoratus*. IV. Change of the amount of blood elements and the electrophoretic pattern of serum protein under the influence of stress." *Bull. Jap. Soc. Sci. Fish.* **34**: 1066-1071 (1968).

J12,696/68

Leibson, L. G., Plisetskaya, E. M.: "Hormonal control of blood sugar level in cyclostomes." *Gen. Comp. Endocrinol. Supp.* **2**: 528-534 (1969). H27,325/69

Review of the literature showing that the chromaffin cells of *cyclostomes* produce catecholamines, and the interrenal cells, corticoids. Changes in the environment as well as surgical and physical stressors of various kinds induce hyperglycemia in cyclostomes, presumably as a result of catecholamine liberation.

Mazeaud, M.: "Adrénalinémie et noradrénalinémie chez la Lamproie marine (*Petromyzon marinus L.*)" (Adrenalinemia and noradrenalinemia in the sea lamprey [*Petromyzon marinus L.*]}. *C.R. Soc. Biol. (Paris)* **163**: 349-352 (1969). H15,743/69

In the *lamprey*, various stressors (surgical trauma, forced exercise, bleeding) greatly increase plasma NEP and to a lesser extent EP concentrations. Presumably these increases

are a nonspecific defense mechanism. Comparable data on other fish are discussed (7 refs.).

Mazeaud, M.: "Influence de stress sur les teneurs en catécholamines du plasma et des corps axillaires chez un Sélaïen, la Roussette (*Scyliorhinus canicula L.*)" (Effects of stress on catecholamine content in the plasma and axillary bodies in a Selachian, the Roussette [*Scyliorhinus canicula L.*]}. *C.R. Soc. Biol. (Paris)* **163**: 2262-2266 (1969).

H26,453/69

In the *Roussette* (spotted dogfish), which possesses no adrenal medulla comparable to that of mammals but has suprarenal and axillary chromaffin bodies, various types of stressors can raise the blood catecholamine concentration, although the changes are generally less pronounced than in mammals and become evident only during intense and prolonged stress. Short exposure may even produce an inverse response. The literature on catecholamine release during stress in other fish and lower vertebrates is briefly reviewed (10 refs.).

Fontaine, M.: "Les poissons migrateurs" (Migrating fish). *Atomes* **24**: 715-720 (1969).

G81,184/69

Brief, semipopular review on the stressor effect of seasonal migration in fish.

Wedemeyer, G.: "Stress-induced ascorbic acid depletion and cortisol production in two salmonid fishes." *Comp. Biochem. Physiol.* **29**: 1247-1251 (1969). H13,688/69

In the coho *salmon* and rainbow trout, interrenal ascorbic acid decreased and serum cortisol increased upon exposure to stressors (cold, forced exercise).

Szakolczai, J.: "Reaction of the intestine of the *carp* (*Cyprinus carpio L.*) to environmental stress." *Acta Vet. Acad. Sci. Hung.* **19**: 153-159 (1969).

J23,971/69

Kimbrell, G. M., Weinrott, M. R., Morris, E. K. Jr., Scheid, J., Sangston, D.: "Alarm pheromone and avoidance conditioning in *goldfish*, *Carassius auratus*." *Nature* **225**: 754 (1970).

H21,093/70

"The alarm reaction in fish is believed to be produced by a chemical substance (pheromone) secreted by specialized cells in the epidermis." A crude preparation of "alarm pheromone," dropped into an aquarium, causes "not only 'fright' and 'alarm' behaviour but also flight or withdrawal." Presumably, the pheromone can enhance avoid-

ance conditioning. [It is not clear whether the "alarm reaction" described here is equivalent to the first phase of the G.A.S. (H.S.).]

Wedemeyer, G.: "The role of stress in the disease resistance of fishes." In: Snieszko, S. F., *A Symposium on Diseases of Fishes and Shell Fishes*, pp. 30-35. Washington, D.C.: Amer. Fish. Soc., Spec. Publ. No. 5, 1970.

J12,695/70

Henderson, I. W., Chan, D. K. O., Sandor, T., Jones, I. C.: "The adrenal cortex and osmoregulation in teleosts." In: Benson, G. K. and Phillips, J. G., *Hormones and the Environment*, pp. 31-55. Cambridge: Cambridge University Press, Mem. Soc. Endocrinol., No. 18, 1970.

E9,136/70

Review on the role of corticoids in osmoregulation among *teleosts*, with a brief section on adrenal responses to various other forms of stress, such as the prolonged swimming without feeding from Europe to spawning grounds 3,000 mi. away.

Pickford, G. E., Srivastava, A. K., Slicher, A. M., Pang, P. K. T.: "The stress response in the abundance of circulating leucocytes in the killifish, *Fundulus heteroclitus*. I. The cold-shock sequence and the effects of hypophysectomy." *J. Exp. Zool.* **177**: 89-96 (1971).

G83,471/71

In the *killifish*, brief immersion in very cold water causes peculiar waves of leucopenia followed by leucocytosis, a phenomenon ascribed to stress. Hypophysectomy inhibits the leukocytic phase.

Pickford, G. E., Srivastava, A. K., Slicher, A. M., Pang, P. K. T.: "The stress response in the abundance of circulating leucocytes in the *killifish*, *Fundulus heteroclitus*. II. The role of catecholamines." *J. Exp. Zool.* **177**: 97-108 (1971).

G83,472/71

Pickford, G. E., Srivastava, A. K., Slicher, A. M., Pang, P. K. T.: "III. The role of the adrenal cortex and a concluding discussion of the leucocyte-stress syndrome." *J. Exp. Zool.* **177**: 109-117 (1971).

G83,473/71

The singular leukocytic response of *killifish* is ascribed to stress. On the basis of some experiments, "a tentative interpretation of the cold-shock sequence is proposed on the assumption that catecholamines (presumably epinephrine) are leucopenic and that cortisol is leucocytic."

Saddler, J. B., Cardwell, R.: "The effect of tagging upon the fatty acid metabolism of

juvenile pink salmon." *Comp. Biochem. Physiol. [A]* **39**: 709-721 (1971).

J19,852/71

In tagged *salmon*, excessive fatty acid transfer from muscle to liver was ascribed to the stressor effect of the operation itself. The literature on other stress manifestations, particularly increased cortisol production in salmons following exposure to various stressors, is reviewed.

Cardwell, R. D., Saddler, J. B., Smith, L. S.: "Hematological effects of Dennison tagging upon juvenile pink salmon (*Oncorhynchus gorbuscha*)."*Comp. Biochem. Physiol. [A]* **38**: 497-508 (1971).

H39,511/71

In juvenile pink *salmon*, implantation of Dennison tags, handling, netting and the length of exposure to anesthetics required for this procedure are considered to be stressors responsible for certain hematologic and plasma protein alterations. [It remains to be proved whether these changes are really characteristic of stress and could be produced by other stressors (H.S.).]

Singley, J. A., Chavin, W.: "Cortisol levels of normal goldfish, *Carassius auratus* L., and response to osmotic change." *Am. Zool.* **11**: 653 (1971).

J12,378/71

In *goldfish*, blood cortisol levels show a clearcut circadian rhythm and a particularly rapid increase following exposure to a variety of stressors.

Baskin, F., Masiarz, F. R., Agranoff, B. W.: "Effect of various stresses on the incorporation of [³H] orotic acid into *goldfish* brain RNA." *Brain Res. (Amst.)* **39**: 151-162 (1972).

Singley, J. A., Chavin, W.: "Serum cortisol in normal goldfish (*Carassius auratus L.*)."
Comp. Biochem. Physiol. [A] **50**: 77-82 (1975). H96,696/75

Data on the circadian rhythm of serum cortisol in normal and cold-stressed goldfish.

Invertebrates

In the cockroach, the corpora cardiaca contain a substance with adrenergic properties alleged to be closer to EP than to NEP. This substance is released during stress and causes temporary paralysis, which presumably has an adaptive value by making the insect inconspicuous and less subject to attack. Similar effects are elicited by extracts of corpora cardiaca. The latter also appear to regulate circadian cycles of activity in this species.

In the desert locust, the intercerebralis-corpora cardiaca system plays a major role in oocyte development. Blood from ovipositing or stressed females accelerates the beat of the locust heart in vitro, and the same effect is obtained by extracts of corpora cardiaca. Another arthropod, the millipede, widely distributed in Louisiana and Mississippi, emits a highly pungent aromatic secretion (consisting of benzaldehyde and hydrogen cyanide) when disturbed in various ways. This substance is discharged by special paired glands and evidently has a defensive function, as it repulses attacking fire ants.

Among other invertebrates, data on nonspecific, usually defensive responses—which

may or may not be closely related to stress as we know it in vertebrates—have been described in the silk worm, grasshopper, house fly, drosophila and a variety of crustaceans and molluscs.

Invertebrates

(See also our earlier stress monographs, p. xiii)

Barton-Browne, L., Dodson, L. F., Hodgson, E. S., Kiraly, J. K.: "Adrenergic properties of the cockroach corpus cardiacum." *Gen. Comp. Endocrinol.* 1: 232-236 (1961).

D13,086/61

Corpora cardiaca extract from the *cockroach* inhibits the contractions of the uterus and colon of the rat but loses much of this property if the roaches are previously exposed to electric shocks. The active principle of the extract is closer to EP than to NEP. When it is injected into roaches, it temporarily paralyzes them. It remains to be shown whether "the release of an adrenergic factor from the corpus cardiacum is necessarily an adaptive reaction to stress, similar to the well-known vertebrate adrenal response."

Hodgson, E. S.: "Hormonal control of reproductive and adaptive behavior. Neurosecretion and behavior in arthropods." *Gen. Comp. Endocrinol.* Supp. 1: 180-187 (1962).

D23,449/62

In *cockroaches*, injection of EP causes a sluggishness similar to that elicited by corpora cardiaca extract or exposure to different stressors. "It remains to be shown, also, to what extent the release of neurosecretory hormones from the corpora cardiaca is normally produced by stresslike stimuli during the life of the animal, and what selective advantage the behavioral results would confer."

Highnam, K. C.: "Variations in neurosecretory activity during oocyte development in *Schistocerca gregaria*." *J. Endocrinol.* 24: iv-v (1962).

D23,864/62

Blood from the pars intercerebralis-corpora cardiaca system of the desert *locust* plays a major role in the control of oocyte development. "Blood from ovipositing and from stressed females will accelerate the rate of beating of the locust heart in vitro. Homogenates of corpora cardiaca also accelerate the rate of heart-beat."

Fukuda, S.: "Endocrine regulation during development. II. Hormonal control of dia-

pause in the silkworm." *Gen. Comp. Endocrinol.* Supp. 1: 337-340 (1962).

D23,465/62

Observations on *silkworms* "led the author to the assumption that the production of diapause or nondiapause eggs is affected by nonspecific stressful stimuli." After localized thermocauterization, trauma, injury to the nervous system, injection of EP, of thyroid preparations, or of air, insertion of a piece of glass or silkworm cocoon into the body cavity, "some of the moths from diapause pupae laid varying number of nondiapause eggs together with diapause eggs and some of those from nondiapause pupae deposited some diapause eggs besides nondiapause eggs."

Blum, M. S., Woodring, J. P.: "Secretion of benzaldehyde and hydrogen cyanide by the millipede *Pachydesmus crassicutis* (Wood)." *Science* 138: 512 (1962).

D36,850/62

When disturbed in various ways, the *millipede Pachydesmus crassicutis* (an arthropod widely distributed in Louisiana and Mississippi) emits a highly pungent aromatic secretion consisting of a mixture of benzaldehyde and hydrogen cyanide. The substance which is discharged by paired glands exerts a defensive function, for example, repulsing attacking fire ants. [Although this reaction is nonspecific, it remains to be proven that it represents a true manifestation of stress elicited by any type of demand (H.S.).]

Plants and Microorganisms

Several investigations suggest that nonspecific stress reactions occur also in plants. The so-called "stress-satellite DNA" is induced in growing seedlings of certain plants when exposed to various stressors. This DNA is presumed to be of bacterial origin and therefore cannot be "taken as evidence for the amplification of ribosomal-RNA genes under this condition of physiological stress."

In tobacco plants grown in culture solution, various stressors impair shoot turgor.

A more detailed discussion of the many data concerning nonspecific stress reactions in plants would be beyond the scope of this treatise.

Plants

(See also our earlier stress monographs, p. xiii)

Zatyko, J.: "A növények életképessé gének növelése 'veszélyt jelző' informaciokkal" (Enhancement of viability of plants by "danger-indicating" information). *Fertődi Növényterm. Kutató, Int. Közl.* **2**: 83-90 (1965) (Hungarian). G78,905/65

Report on experiments "extending to plants the validity of the theory of 'stress' elaborated by Selye in animal tests. The present experiments deal with the case of 'cross resistance' or 'nonspecific resistance' of fun-

damental importance in the theory of 'stress'" (7 refs.).

Cannon, R. E., Shane, M. S.: "The effect of antibiotic stress on protein synthesis in the establishment of lysogeny of *Plectonema boryanum*." *Virology* **49**: 130-133 (1972). G92,363/72

Evidence is presented for the establishment of lysogeny in *Plectonema boryanum* by LPP-1D and LPP-2 phycoviruses after treatment of the alga with chloramphenicol.

Mizrahi, Y., Richmond, A. E.: "Hormonal modification of plant response to water

stress." *Aust. J. Biol. Sci.* **25**: 437-442 (1972). G92,927/72

In tobacco plants grown in culture solution, various stressors impaired the water balance as evidenced by a decline of shoot turgor.

Pearson, G. G., Ingle, J.: "The origin of stress-induced satellite DNA in plant tissues." *Cell Different.* **1**: 43-51 (1972).

G90,501/72

A so-called "stress-satellite DNA" is induced in growing seedlings of various *Cucurbitaceae* exposed to darkness, trauma and other stressors. The present observations suggest that, in response to cold storage, the appearance of the stress-satellite is of bacterial origin and therefore cannot be "taken as evidence for the amplification of the ribosomal-RNA genes under this condition of physiological stress."

Zatyko, J.: "Érvényes-e a növényekre Selye stress-elmélete?" (Is Selye's stress theory applicable to plants?) *Az élet és Tudomány Kalendáriuma* **73**: 37-41 (1973) (Hungarian). G96,678/73

Brief summary in lay language of scientific evidence indicating that stress can occur in plants.

Newman, E. I.: "Competition and diversity in herbaceous vegetation." *Nature* **244**: 310 (1973). H78,385/73

Few species develop at "low-stress" sites where conditions for growth of herbaceous vegetation are highly favorable, in comparison with intermediate-stress sites.

Zatyko, J. M.: "Effect of low concentration colchicine on the cytokinin content of pinto bean leaves." *Naturwissenschaften* **60**: 105-106 (1973). J5,100/73

In pinto beans (*Phaseolus vulgaris L.*), treatment with synthetic cytokinins enhances resistance to various noxious agents (for example, high or low temperatures, fungi, viruses, chemical mutagens, colchicine and so

on). "The data support the idea that there may be a non-specific protective mechanism, in which significance is attributed to cytokinin hormones. We venture to compare it with Selye's stress theory, which describes the endocrinologic basis of the non-specific protective mechanism of the body. Corticoids, the adrenal hormones, play an important role in this mechanism and we suggest that cytokinins in plants may play an analogous role to corticoids in man."

Lacroix, L. J., Nalborczyk, E.: "The effect of low temperature acclimation on temperature sensitive carbon dioxide exchange of rape seedlings" (abstracted). *Proc. Can. Fed. Biol. Soc.* **17**: 101 (1974). H92,134/74

"Most plants respond to low temperature stress (acclimation) by metabolic changes which result in increased frost tolerance."

Coxon, D. T., Price, K. R., Howard, B., Osman, S. F., Kalan, E. B., Zacharius, R. M.: "Two new vетисpirane derivatives: stress metabolites from potato (*Solanum tuberosum*) tubers." *Tetrahedron Lett.* No. 34: 2921-2924 (1974). J20,766/74

Chemical description of vетисpirane and other sesquiterpenes, which are considered to be "stress metabolites" obtainable from infected potato tubers.

Microorganisms

Bissonnette, G. K., Jezeski, J. J., McFeters, G. A., Stuart, D. G.: "Influence of environmental stress on enumeration of indicator bacteria from natural waters." *Appl. Microbiol.* **29**: 186-194 (1975).

J22,070/75

"Bacterial cells may become physiologically injured due to the environmental stress imposed by the aquatic environment" (25 refs.).

TUMORS

It is hardly surprising that both experimental and spontaneous tumors can evoke typical manifestations of the G.A.S. since they are evidently severe stressors. Very large, necrotizing transplantable tumors also produce certain hitherto unexplained,

apparently more specific changes, namely extramedullary hemopoiesis, especially in the spleen, liver and adrenals.

Tumors

(See also our earlier stress monographs, p. xiii)

McEuen, C. S., Selye, H.: "Histologic changes in the adrenals of tumor-bearing rats." *Am. J. Med. Sci.* **189**: 423-424 (1935). 36,705/35

In rats bearing large necrotizing Walker tumors, the adrenals were enlarged and contained many lymphocytic and leukocytic infiltrations. Since similar islands are occasionally seen after various infections, they cannot be regarded as specific to tumors.

Hilf, R., Burnett, F. F., Borman, A.: "The effect of Sarcoma 180 and other stressing agents upon adrenal and plasma corticosterone in mice." *Cancer Res.* **20**: 1389-1393 (1960). C94,528/60

In mice, growing Sarcoma 180 tumors cause adrenal and plasma corticoid changes similar to those obtained with other stressors.

Hilf, R., Breuer, C., Borman, A.: "The effect of Sarcoma 180 and other stressing

agents upon adrenal adenine nucleotide-metabolizing enzymes." *Cancer Res.* **21**: 1439-1444 (1961). D15,008/61

In mice, Sarcoma 180 transplants caused typical stress reactions, with a rise in blood corticoids and an increase in adrenal ATPase activity. "Liver 5'-nucleotidase activity was elevated by tumor growth but not altered by the other stresses studied."

Moore, D. C., Holton, C. P., Marten, G. W.: "Psychologic problems in the management of adolescents with malignancy. Experiences with 182 patients." *Clin. Pediatr.* **8**: 464-473 (1969). J22,517/69

Ertl, N.: "'Systemic effects' during the growth of malignant experimental tumors." *Oncology (Basel)* **27**: 415-429 (1973).

J6,691/73

In rats bearing Walker carcinosarcomas, there is thymus atrophy and adrenal hypertrophy in association with hepatomegaly. [These are deemed to be the "systemic effects" of growing tumors without considering the possible role of stress (H.S.).]

COMBINED EFFECT OF VARIOUS AGENTS

(See also Resistance under Characteristic Manifestations of Stress [Functional Changes] and Treatment)

Multiple Stressors (Cross-resistance and Cross-sensitization)

Even the earliest studies on the G.A.S. showed that several stressors applied simultaneously can have a cumulative effect. For example, cold and hunger decrease resistance to almost any stressor, and concurrent application of various drugs and/or physical agents may result in the summation of their stressor potency. In this case, it became customary to speak of "cross-sensitization." On the other hand, during or immediately following an alarm reaction produced by one stressor, there may develop a "cross-resistance" against the damaging effect of another. In all these instances, it is very important to distinguish between specific and truly nonspecific or stressor effects. Certain agents may augment or diminish each other's toxicity merely because one increases or decreases the specific effect of the other. For example, all specific antidotes, blocking agents and remedies work through this type of mechanism, just

as do factors that cause specific hypersensitivity. These pharmacologic interactions do not fall within the scope of this monograph; here, we shall consider only evidence of nonspecific, that is, stress-induced, changes in resistance.

As we saw in the section on age as a conditioning factor, the literature is somewhat contradictory with regard to the effect of handling and gentling neonatal rats upon their resistance to various stressors later in life. This may depend upon differences in the experimental conditions used by various investigators, but the subject as such is certainly pertinent to the problem of cross-resistance as originally defined.

Most of the so-called exogenous conditioning agents may be regarded as acting through cross-resistance or cross-sensitization, as long as their effect is nonspecific.

According to one theory, schizophrenics are less responsive to stressors because they are already under stress, and virtually all forms of so-called nonspecific prophylaxis and therapy (for example, muscular exercise, hot or cold baths, shock treatments, and so on) are actually instances of cross-resistance. The phenomenon has also been found in a local variant in that topical tissue resistance can be produced by repeated application of different stressors to the same body region or even by a systemically applied agent having a topical stressor effect. The most striking demonstrations of local cross-resistance and cross-sensitization have been observed using the granuloma pouch technique, which permits the concurrent or consecutive application of several stressors to the same tissue region.

A perusal of the literature on systemic and local cross-resistance reveals that many of the statements are apparently contradictory, one study showing an increase, another a decrease, in resistance following exposure to stress under seemingly identical conditions. It must be kept in mind, however, that cross-resistance or cross-sensitization depends on a large number of factors, such as duration and intensity of the stressor action, associated specific effects of the stressors, age, genetic background, species susceptibility, and so on. That is why the interested reader must primarily consult the original publications cited in this section and should interpret each case with the preceding considerations in mind. The only valid generalization that we can make is that under appropriate conditions both cross-sensitization and cross-resistance can be produced at will by the consecutive application of various stressors.

Undoubtedly, a preparatory overproduction and secretion of certain stress hormones by the hypophysis and the adrenals may play an important role; for example, an increased glucocorticoid discharge elicited by a stressor can surely augment resistance to agents which are damaging mainly because they provoke responses (inflammation, immune reactions) whose suppression is advantageous under given conditions. On the other hand, a preparatory slow discharge of potentially noxious reserves of hormones and other endogenous toxic metabolites may likewise be beneficial in offering protection against severe stressors whose toxicity is due mainly to a sudden flooding of the organism by substances of this type. In any event, it is unlikely that all forms of cross-resistance and cross-sensitization could be dependent upon a single mechanism; that is, a pituitary or adrenal hormone discharge could hardly be implicated in those types of cross-resistance that have been demonstrated after hypophysectomy or adrenalectomy.

One review (Selye, C95,972/61, p. 446) deals with most of the fundamental aspects involved in nonspecific or cross-resistance and sensitization; it provides a more detailed analysis of the pertinent literature than can be given here.

Multiple Stressors (Cross-resistance, Cross-sensitization)

(See also our earlier stress monographs, p. xiii, and cf. Resistance under Morphology)

Selye, H.: "Studies on adaptation." *Endocrinology* **21**: 169-188 (1937).

38,798/37

In rats, "hunger and cold are very active factors in aggravating the effects of alarming stimuli. In fact, cold or any other stimulus which is able to cause an alarm reaction by itself acts in a similar way. Thus it is possible, for instance, to obtain a typical alarm reaction by giving one quarter of the alarming dose of 4 different drugs within 48 hours, although one quarter of the alarming dose of any one of these drugs has no effect by itself."

Selye, H.: "The prevention of adrenalin lung edema by the alarm reaction." *Am. J. Physiol.* **122**: 347-351 (1938). A7,154/38

In rats, an alarm reaction produced by EP, formaldehyde, cold, forced exercise or surgical trauma increases resistance to the lung edema elicited by subsequent intravenous injection of EP. "This observation invalidates the possibility that the alarm reaction increases resistance only because it delays the absorption of toxic agents into the blood stream." The pulmonary edema normally produced in rats given large amounts of intravenous sodium chloride after bilateral nephrectomy can be prevented by an alarm reaction (forced exercise). This is a good example of cross-resistance.

Fischer, R., Agnew, N.: "A hierarchy of stressors." *J. Ment. Sci.* **101**: 383-386 (1955). C7,812/55

Schizophrenic patients may be less responsive to stressors because they are already under stress. "The concept of a hierarchy of stressors is introduced. Such a concept explains the different adaptive answers elicited if an organism is threatened (1) by a life stressor of primary importance or (2) by 'alarming' stimuli directed toward less basic urges and needs. Stressors of primary importance may establish new adaptive responses, while stressors perceived as less important are practically disregarded if the organism is already under stress of similar importance and magnitude."

Adolph, E. F.: "General and specific

characteristics of physiological adaptations."

Am. J. Physiol. **184**: 18-28 (1956).

C12,038/56

In rats, adaptation was induced to single stressors such as cold air, simulated altitude, hypoxia, water, sodium chloride or sucrose. In most cases, after discontinuation of stressor treatment the disappearance of adaptation was slower than its induction. There was cross-resistance between some stressors, but more often adaptation was specific (28 refs.).

Griffiths, M. E., Calaby, J. H., McIntosh, D. L.: "The stress syndrome in the rabbit." *C.S.I.R.O. Wildl. Res.* **5**: 134-148 (1960).

D12,295/60

Detailed description of the stress syndrome in the wild rabbit, in which adrenal ascorbic acid content is very variable and cortical lipid granules increase after the animal has been kept in the laboratory for a "settling-in period." Cold has little effect on cortical ascorbic acid or lipid droplets, but subcutaneous formalin causes a threefold increase in adrenal size. Noise gives "cross-resistance" to cold, but formalin does not.

Winokur, G., Stern, J. A., Graham, D. T.: "Stress as an inhibitor of pathological processes." *Psychiatr. Res. Rep. APA* **12**: 73-80 (1960).

J11,150/60

In cancer-susceptible mice, various stressors inhibit the loss of hair caused by painting with methylcholanthrene.

Bajusz, E., Selye, H.: "Adaptation to the cardiac necrosis-eliciting effect of stress." *Am. J. Physiol.* **199**: 453-456 (1960).

C83,948/60

"True cross-resistance to the cardiotoxic action of various stressors can be demonstrated under these circumstances, in rats sensitized by F-COL [9α -fluoro-hydrocortisone] and Na-acetate: the cardiac necrosis-producing effect of muscular exercise could be prevented by pretreatment with cold, that of cold by muscular exercise, that of noradrenaline by restraint, that of restraint by noradrenaline, and that of bone fractures by muscular exercise."

McMichael, R. E.: "The effects of preweaning shock and gentling on later resistance to stress." *J. Comp. Physiol. Psychol.* **54**: 416-421 (1961).

G46,161/61

Review of the literature and personal observations on the effect of various stressors (administered immediately after birth) upon resistance to other stressors in later life.

Selye, H., Bajusz, E., Strelbel, R.: "Cross-resistance to cardiotoxic agents." *Can. J. Biochem.* **39**: 519-525 (1961). C90,422/61

The ESCN produced in rats by various stressors in combination with fluorocortisol and sodium salts could be prevented by gradual adaptation to the stressors.

Selye, H.: "Nonspecific resistance." *Ergeb. Allg. Pathol. Pathol. Anat.* **41**: 208-241 (1961). C95,972/61

Extensive review on nonspecific or cross-resistance and sensitization, with numerous instances of both the systemic and the local variants. Very often stressors are used to induce this type of resistance as, for example, in the so-called "nonspecific therapy." Protection by stressors against the most diverse inflammatory lesions is particularly striking, and certain types of cross-resistance are demonstrable even in adrenalectomized animals. In some cases, increased thyroid hormone secretion also appears to induce tolerance. A special section is devoted to interrelations between systemic and local nonspecific resistance, that is, the influence of the L.A.S. upon the G.A.S. and vice versa (85 refs.).

Selye, H.: "Nonspecific resistance." *Patol. Fiziol. Éksp. Ter.* **5** No. 3: 3-14; No. 4: 3-15 (1961) (Russian). C99,248/61

Review on stress, especially in relation to nonspecific resistance.

Selye, H.: "Stress and cardiovascular disease." *World Wide Abstr. Gen. Med.* **4**: 8-13 (1961). C93,900/61

Review on the effect of stress upon the development of cardiovascular disease, particularly CHD. Special emphasis is placed upon the production of cardiac necrosis following humoral conditioning by sudden exposure to unaccustomed stress, and upon the fact that previous exposure to a stressor (for example, exercise) can protect the heart against this type of damage.

Schutz, K.: "Practical application of Selye's stress concept." *Ulster County Med. Bull.* **11**: 16-17 (1962). D43,449/62

Brief résumé of the literature concerning the therapeutic actions of stressors.

Strelbel, R., Bajusz, E., Selye, H.: "Fasting as a protective stressor against the potential cardiotoxic action of various agents." *Cardiologia* (Basel) **41**: 179-190 (1962).

C95,845/62

"In the rat fasting can protect the heart

against the production of necrosis, inflammation and/or calcification by various agents such as: plasmocid, papain, dihydrotachysterol plus NaH_2PO_4 , dihydrotachysterol plus Ca-acetate, nephrectomy plus $\text{Na}_3\text{citrate}$ and restraint after sensitization with fluorocortisol plus Na-acetate. These observations furnish additional examples of stress-induced cross-resistance of cardiac muscle, assuming that here—as in earlier experiments with other stressors—fasting acts through its nonspecific effect."

Leonov, B. V., Lomova, M. A., Rudakov, I. A.: "Connection of radiosensitivity of rats with antioxidative activity of bone marrow and content of unesterified fatty acids in their blood under conditions of 'stress.'" *Radiobiologia* **3**: 518-522 (1963) (Russian). Engl. trans.: *Radiobiology* **3**: 43-49 (1963). J24,546/63

Experiments on rats "suggested that the increased expenditure of antioxidants under conditions of 'stress' may be connected with mobilization of fats from fat depots and that one of the mechanisms of the increase of radiosensitivity of animals in 'stress' can be the oxidation of mobilized lipids." It is assumed that cross-sensitization by stressors to x-rays may result from the loss of antioxidants during stress.

Broadbent, D. E.: "Differences and interactions between stresses." *Q. J. Exp. Psychol.* **15**: 205-211 (1963). J11,836/63

In man simultaneous application of different stressors showed that "the effects of heat appear to be independent of those of noise and sleeplessness, while the latter two conditions partially cancel each other. It is therefore argued that noise and sleeplessness affect the same mechanism in opposite directions, while heat affects some other mechanism. Tentatively, noise is regarded as over-arousing and lack of sleep as under-arousing."

Swinyard, E. A., Miyahara, J. T., Clark, L. D., Goodman, L. S.: "The effect of experimentally-induced stress on pentylenetetrazol seizure threshold in mice." *Psychopharmacologia* (Berlin) **4**: 343-353 (1963).

E21,626/63

Various stressors decreased the pentylenetetrazol seizure threshold in mice.

Wallgren, H., Tirri, R.: "Studies on the mechanism of stress-induced reduction of alcohol intoxication in rats." *Acta Pharmacol. (Kbh.)* **20**: 37-38 (1963). E25,256/63

Review of the literature showing that various stressors (fear, trauma) have a sobering effect on ethanol intoxication. A similar action of exercise has been demonstrated in rats. This type of cross-resistance is not prevented by hypophysectomy.

Pirozyński, T., Parus, N.: "Les modifications neuro-endocrines déterminées par le stress thérapeutique appliquée aux malades psychiques" (Neuroendocrine changes caused by therapeutic stress applied to mental patients). *Ann. Méd. Psychol.* **1**: 567-593 (1964). G13,498/64

Selye, H., Gabbiani, G., Tuchweber, B.: "Protection by restraint against parathyroid-extract intoxication in absence of the adrenals." *Am. J. Physiol.* **207**: 573-576 (1964). E24,132/64

Restraint protects the rat against the soft tissue calcification normally produced by large doses of parathyroid extract. This protection is evident even in adrenalectomized animals maintained on corticoids.

Gauron, E.: "Infantile shock traumatization and subsequent adaptability to stress." *J. Genet. Psychol.* **104**: 167-178 (1964).

J22,968/64

In rats, "previous experience with shock produced decremental performance on a stressful test involving the repetition of shock, but not on a stressful test not involving shock nor on a nonstressful test."

Fridrich, R.: "Die Auswirkungen von Kombinationsschäden auf den bestrahlten Organismus" (The effects of combined stress on the irradiated organism). *Strahlentherapie* **124**: 302-307 (1964). G19,723/64

In mice, production of stress by traumatic injuries (removal of part of the omentum) forty-eight hours before or after x-irradiation offers considerable protection. This type of increased resistance is ascribed to the stressor effect of pituitary-adrenocortical mobilization, ("cross-resistance") since it can be blocked by morphine or barbiturates that inhibit hypothalamic reactivity (40 refs.).

Jahnke, V.: "Stress and pathologic calcification." *J. Am. Osteopath. Assoc.* **65**: 258-267 (1965). J23,646/65

Most experimental calciphylactic syndromes can be prevented by pretreatment with stressors.

Stahnke, H. L.: "Stress and the toxicity of venoms." *Science* **150**: 1456-1457 (1965). F57,253/65

The resistance to scorpion or rattlesnake venom is diminished by previous exposure to various stressors.

Technique for studying the interaction between a physical (cold) and an interpersonal (severe criticism) stressor in man.

Sanchez, C., Miya, T. S., Bousquet, W. F.: "Effects of conditioning upon stress responses in the rat." *Proc. Soc. Exp. Biol. Med.* **123**: 615-618 (1966). F73,973/66

Pretreatment of rats with small amounts of intravenous sodium chloride for five days inhibited the marked elevation of plasma corticosterone induced by saline in unpretreated controls. Similar pretreatment offered no protection however, against the more pronounced stressor effect of intravenous histamine. The resting plasma corticosterone and ascorbic acid levels did not show any consistent seasonal variations, and there was no manifest relationship between the two values. This "suggests that caution be employed in relying upon adrenal ascorbic acid determinations as an index of adrenocortical activity or response to stressors."

Ducommun, P., Vale, W., Sakiz, E., Guillemin, R.: "Reversal of the inhibition of TSH secretion due to acute stress." *Endocrinology* **80**: 953-956 (1967). F83,273/67

In rats, chronic mild stress (transfer from the animal room to the laboratory, handling and brief ether anesthesia at different times of the day) prevents the usual inhibition of TTH secretion by acute stress (sojourn in a noisy centrifuge). This inhibition is also reversed by reserpine. Furthermore, chronic stress leads to continuously increased resting levels of plasma TTH.

J17,473/74

Studies on plasma and adrenal corticosterone in rats exposed to different stressors (heat, restraint, noise) alone or in combination. "A moderate increase in the levels of both plasma and adrenal corticosterone was observed after 24 hrs of hypokinesia. In a subsequent period of 60 days the corticosterone levels did not differ significantly from the levels found in the control animals. However, a marked decrease in adrenal weight and a slighter response to additional thermal stress were demonstrated after 60 days of hypokinesia. Differences between the restrained and the control animals were also found in the adaptation to chronic auditory stress."

III. CHARACTERISTIC MANIFESTATIONS OF STRESS

In this chapter, we shall discuss all the functional, chemical and morphologic changes that are truly nonspecific and which hence characterize the stress response. Some of these are of diagnostic value in that they permit us to recognize stress. A special section is devoted to the so-called "stress tests" that are commonly used to determine whether a procedure or activity is particularly stressful, or to predict how a person is likely to respond to stressors as, for example, in responsible administrative posts, or in emergencies during catastrophes, fires, combat or aviation.

Another reason why we had to devote such a large section to the characteristics of stress is that, in medical research, we are continuously faced with the necessity of distinguishing specific symptoms and signs of disease, or actions of remedies, from their nonspecific side effects. It is somewhat arbitrary to separate the "physiologic" manifestation of stress from the progression of the same effect to a point where we would call it pathologic, that is, a stress-induced malady. Hence, the reader should also consult Chapter IV, Diseases of Adaptation. For example, minor stress-induced changes in behavior, cognition, and emotion will be discussed in this chapter under Nervous System, whereas major, definitely morbid derangements of a similar kind will be found in the section, Neuropsychiatric Diseases of Adaptation.

CHEMICAL CHANGES

Most of the studies concerned with the biochemistry of stress have dealt with hormones and hormone-like substances. One reason for this is that the G.A.S. was first characterized on the basis of observations on the mediating role of the hypophysis-adrenocortical axis. Furthermore, even today, we know much more about this field; the neuroendocrine mechanisms that transmit the initial stimulus of the "First Mediator" humoral substances (for example, CRF, EP, NEP, 5-HT) are recognized as playing a decisive role.

However, many other biochemical changes, not involved in the actual mediation of the stress response, proved to be characteristic of it. Hence, we shall also have to deal here with alterations in body weight and in the BMR as well as in the metabolism of lipids, proteins, carbohydrates, electrolytes and enzymes.

Body Weight

In the earliest studies a loss of body weight was recognized as a particularly characteristic response to stress, no matter how produced. Usually, the general catabolism

of energy-yielding materials responsible for this change is most intense during the first days, after which the rate of weight loss tends to diminish. The reason for this reaction is that most stressors cause a decrease in appetite and hence in caloric intake, so that the requirements must be supplied by endogenous sources, namely, the breakdown of fat, protein and carbohydrate stores.

Paradoxically, sometimes—especially under the influence of chronic psychogenic stress of moderate intensity—people have a tendency to eat more, because a full stomach has a tranquilizing effect and also takes their mind off the psychogenic irritant to which they are exposed. Such people tend to become overweight as they are driven to food in a manner very similar to that of subjects who turn to alcohol or drugs for much the same reason.

Body Weight

Hart, J. S., Heroux, O.: "Utilization of body reserves during exposure of mice to low temperatures." *Can. J. Biochem.* **34**: 414-421 (1956). E93,320/56

"Mice acclimated for four weeks to 6°C had a body water content on an absolute and on a fat-free basis that was greater than that of mice acclimated to 23°C. When exposed to freezing temperatures, the weight loss and loss of water were greater in the cold acclimated group. Fat was the major tissue energy reserve utilized under these conditions. In both acclimation groups it accounted for 85 to 89% of the total calories, the remainder being supplied mostly by protein." The results are discussed in relation to the catabolic changes characteristic of stress.

Basal Metabolic Rate (BMR)

Surprisingly few investigators have dealt with changes in the BMR during stress. Of course, it is generally known that in very severe stress, as exemplified by the final stages of traumatic, hemorrhagic or toxic shock, the BMR decreases, whereas the reverse is true in the acute alarm reaction, for example, that produced by pain, emotional arousal, or extreme muscular effort. However, the BMR is particularly subject to conditioning factors which influence it through specific effects; hence it is not a very reliable characteristic of stress.

Basal Metabolic Rate (BMR)

(See also our earlier stress monographs, p. xiii)

Cannon, W. B.: "Traumatic shock." In: Lewis, D., Pool, E. H. et al., *Surgical Monographs*, p. 201. New York and London: D. Appleton, 1923. E142/23

Early observations on soldiers wounded during World War I and severely injured experimental animals concerning the decrease in BMR produced by trauma and hemorrhage. It can largely be overcome by appropriate blood transfusions and may be due to reduced oxygen supply.

Jugenburg, A.: "Über die Einwirkung der Röntgenbestrahlung auf den Gasstoffwechsel Experimentelle Untersuchungen an Meerschweinchen" (The effect of x-irradiation on oxygen consumption in guinea pigs). *Acta Radiol.* (Stockh.) Supp. 3: 168-169 (1928). A32,641/28

In severely x-irradiated guinea pigs, the BMR decreases.

Post, R. S., Visscher, P. H., Wiggers, C. J.: "Sequential changes in oxygen consumption during oligemic and normovolemic shock, and their meaning." *Am. J. Physiol.* 153: 71-80 (1948). B25,993/48

Studies on dogs in normovolemic and oligemic shock produced by hemorrhage with or without restoration of the withdrawn heparinized blood show that reduction of oxygen consumption is not a necessary concomitant of irreversible shock. "Even when body temperature is kept constant oxygen consumption is not a measure of basal metabolic rate during shock. This is due to the fact that oxygen uptake is predominately affected by reduction in oxygen transport capacity, excessive respiratory effort and varying degrees of acidosis with accumulation of oxygen debt."

Kirschner, L. B., Prosser, C. L., Quastler, H.: "Increased metabolic rate in rats after x-irradiation." *Proc. Soc. Exp. Biol. Med.* 71: 463-467 (1949). B37,743/49

Pressor Test, Flickerlicht, Lärm, körperliche Arbeit" (Individual differences in the reaction of circulation and oxygen consumption to standardized stress. Cold Pressor Test, flicker-light, sound, muscular work). *Arch. Kreislaufforsch.* 30: 1-2 (1959).

C72,354/59

Extensive review on changes in the BMR and circulatory apparatus induced in man by the Cold Pressor Test, light, sound, muscular work and other stressors.

Paré, W. P.: "Premature aging as a function of long-term environmental stress." *J. Genet. Psychol.* 104: 185-191 (1964).

G41,960/64

A review on the relationship between stress and aging revealed that with old age the BMR decreases and the prostate undergoes hypertrophy. In experiments on rats chronically exposed to stressors (sound, electric shocks), aging defined in terms of BMR and prostatic hypertrophy, was in fact accelerated. The animals also showed eosinopenia and lymphopenia. It was concluded that "an animal's environment may 'require' or 'cause' adaptive responses that produce irreversible damage and hence shorten lifespan. A concept such as 'normal' aging may be misleading since aging cannot be represented as a unitary concept. Aging is the cumulative effect of responses made by biological systems as these systems adapt themselves to environmental stressors" (21 refs.).

Mitkova, N.: "Changes in the metabolism and in the functional activity of the thyroid in workers exposed to noise and vibrations." *Abstr. Bulg. Sci. Lit. Biol. Med.* 8: 51 (1965).

F47,432/65

In boilermiths, exposure to vibration and noise during their work increases the BMR.

Strydom, N. B., Wyndham, C. H., Williams, C. G., Morrison, J. F., Bredell, G. A. G., Joffe, A.: "Oral/rectal temperature differences during work and heat stress." *J. Appl. Physiol.* 20: 283-287 (1965).

G27,148/65

Studies on the relationship of the BMR to oral and rectal temperatures under different conditions. Despite the title, the authors made no effort to show a relationship to stress, and presumably studied the specific effects of work at different temperatures.

Harrison, T. S., Seaton, J. F., Feller, I.: "Relationship of increased oxygen consump-

tion to catecholamine excretion in thermal burns." *Ann. Surg.* **165**: 169-172 (1967).

G44,078/67

In seriously burned patients an increase in BMR occurs simultaneously with a rise in the excretion of EP and NEP. Catecholamines may help to provide the burned patient with an increased energy supply from oxidatively available stores of fat and muscle (13 refs.).

Macho, L., Palkovič, M., Mikulaj, L., Kvetňanský, R.: "Tissue metabolism in rats adapted to immobilization stress." *Physiol. Bohemoslov.* **17**: 173-178 (1968).

Bünte, H.: "Der Energiehaushalt des chirurgischen Patienten" (The energy metabolism of postoperative patients). *Bruns Beitr. Klin. Chir.* **216**: 577-586 (1968).

G83,616/68

In postoperative patients the BMR rises concurrently with body temperature and tissue catabolism. The contrary is true later, during the anabolic recovery phase (50 refs.).

Corson, S. A., Corson, E. O., Kirilcuk, V., Hajek, J., Hajkova, M.: "Individual differences in oxygen consumption under emotional stress." *Fed. Proc.* **28**: 648 (1969).

H10,465/69

Depending upon racial or constitutional factors, certain dogs respond to the emotional stress of an anticipated "fight-or-flight" situation with a rise in BMR even if they do not actually perform excessive muscular work.

Oyama, J., Chan, L.: "Oxygen consumption and carbon dioxide production in rats during acute centrifugation stress and after adaptation to chronic centrifugation." *Fed. Proc.* **32**: 392 (1973).

H67,544/73

In rats, stress produced by continuous centrifugation causes a pronounced hypothermia and a decrease in BMR. However, with continued exposure to the stressor, adaptation occurs and the BMR rises above normal. The authors conclude that "the principal factor responsible for the centrifugation stress-induced hypothermia in rats is a decrease in their rate of heat production."

HORMONES AND HORMONE-LIKE SUBSTANCES

Corticoids

The abstracts presented in this section deal primarily with the effect of various stressors upon plasma and urinary corticoids as well as their metabolites. Some data are also presented on the changes in the corticoid content of tissues (for example, the brain, muscles, CSF) but in this regard, the pertinent literature is too scanty for detailed evaluation.

The most striking data in the literature abstracted in this section reveal the fairly regular and intense increase in glucocorticoid secretion—observed primarily in man but also in many other species such as the monkey, rabbit, rat, fish—under the influence of various stressors.

Evidence of increased glucocorticoid production in man has been noted especially during the anxiety preceding surgery, in stress induced by surgical operations, burns, malignancies and other diseases, aircraft piloting, vibration, the work of underwater demolition teams, circadian variations, electroshock, shift work, and various types of emotional arousal, including sitting for academic examinations.

In several studies, a rise in mineralocorticoids, particularly aldosterone and 18-OH-DOC, has also been observed in people discussing "stressful subjects," sitting for examinations, experiencing preoperative anxiety, undergoing electroshock and being admitted to intensive care units.

In general, these increases in corticoid production were associated with other manifestations of stress, such as enhanced catecholamine and STH secretion, eosinopenia, fibrinolysis.

It is well known that after going through the stages of alarm and resistance, an organism kept in a state of continuous stress eventually reaches the stage of exhaustion. This is characterized by the loss of all adaptability and by changes in the adrenals which suggest hyperactivity similar to that of the alarm reaction. These alterations are sometimes accompanied by hemorrhages and small necrotic lesions, at least in certain animals exposed to stressors that may have a specific adrenotoxic effect.

Such findings have led many investigators to speak of "adrenal exhaustion." While this may occur under very special conditions (for example, in the Waterhouse-Friderichsen syndrome or after severe damage with diphtheria toxin), it is certainly not often observed in patients exposed chronically to common stressor agents. In fact, studies on agonal patients revealed an impaired metabolism of corticoids, despite continued secretion by the adrenals. Under these conditions, terminal patients excreted most of their 17-OHCS in conjugated form.

Radiocortisol, injected intracardially, is rapidly excreted in rats under normal conditions, but during stress its clearance from the muscles (the main area of storage) is greatly delayed.

Some investigators emphasized that adrenal ascorbic acid depletion does not closely parallel the rise in plasma corticoids during stress; hence, the former cannot be regarded as a reliable indicator of corticoid synthesis and/or release.

During the NASA Gemini VII mission, one group of investigators reported a striking decrease of 17-OHCS during flight. Another study called attention to an inflight rise in aldosterone excretion, and concluded that the secretion of this hormone may be one characteristic of man's adaptation to a weightless environment.

Contrary to expectations, the presumably severe emotional stress preceding suicide as well as depressive illness itself is not associated with high levels of cortisol in the cerebral cortex, whereas patients who died from stressful somatic diseases exhibited elevated brain cortisol, proportionate to the duration and severity of their physical illness.

In some instances, it has been possible to show that treatment with exogenous corticoids partially inhibits the stress-induced excess endogenous corticoid production through the well-known feedback mechanism.

Only a few studies have attempted to identify individual corticoids and their metabolites in the adrenal venous blood.

After perusing the data in this section, the reader is advised also to consult the section on hormone secretion in the discussions devoted to each Stressor and Conditioning Agent.

Corticoids

C20,121/56

In agonal patients the plasma clearance of intravenous radiocortisol was delayed, and terminal patients excreted most of the 17-OHCS in conjugated form. These and other findings are interpreted as indicating that elevated plasma corticoid levels in dying patients "are due to impaired metabolism of these steroids in the presence of continued production and secretion of steroids by the adrenal cortex at normal or reduced rates."

Hume, D. M., Nelson, D. H., Miller, D. W.: "Blood and urinary 17-hydroxycor-

ticosteroids in patients with severe burns." *Ann. Surg.* **143**: 316-329 (1956).

C15,326/56

17-OHCS in the plasma and urine of severely burned patients was greatly increased, and subsequent examinations revealed no evidence of adrenal exhaustion. Indeed, the adrenal was capable of responding to exogenous ACTH during the postburn period (10 refs.).

Nelson, D. H.: "Adrenocortical secretion and factors affecting that secretion." In: Selye, H. and Heuser, G., *Fifth Annual Report on Stress*, pp. 169-184. New York: MD Publications, 1956.

C15,956/56

Review of the literature and personal observations on the identification of individual corticoids secreted under the influence of various stressors into the adrenal venous blood in different species (145 refs.).

Nelson, D. H., Egdahl, R. H., Hume, D. M.: "Corticosteroid secretion in the adrenal vein of the non-stressed dog exposed to cold." *Endocrinology* **58**: 309-314 (1956).

D85,585/56

In dogs, the 17-OHCS concentration of adrenal venous blood was elevated subsequent to surgical trauma and following warming after a period of exposure to cold.

Lamson, E. T., Elmadjian, F., Hope, J. M., Pincus, G., Jorjorian, D.: "Aldosterone excretion of normal, schizophrenic and psycho-neurotic subjects." *J. Clin. Endocrinol. Metab.* **16**: 954 (1956).

C14,904/56

In schizophrenics, aldosterone excretion is somewhat diminished on the average, but individual variations are very great. Insulin shock treatment causes a rise in aldosterone elimination.

Schwartz, T. B., Shields, D. R.: "Urinary excretion of formaldehydogenic steroids and creatinine. A reflection of emotion tension." *Psychosom. Med.* **18**: 159-172 (1956).

C25,345/56

In students undergoing stressful final examinations, increased urinary corticoid excretion occurs fairly regularly, but urinary volume and creatinine elimination are not clearly related to this stressor.

Firschein, H. E., Venuto, F. de, Fitch, W. M., Pearce, E. M., Westphal, U.: "Distribution of injected cortisol-4-C¹⁴ in normal and shocked rats." *Endocrinology* **60**: 347-358 (1957).

J10,793/57

In rats, radiocortisol injected intracardially is rapidly excreted under normal conditions. However, after stress or injection of corticosterone, clearance from muscles (the main area of storage) is greatly delayed. The same is true after tourniquet shock.

Venning, E. H., Dyrenfurth, I., Beck, J. C.: "Effect of anxiety upon aldosterone excretion in man." *J. Clin. Endocrinol. Metab.* **17**: 1005-1008 (1957).

C38,804/57

In students sitting for oral examinations, the degree of anxiety was graded in terms of an arbitrary scale. The rise in aldosterone excretion roughly paralleled the degree of anxiety and was associated with increased 17-OHCS elimination.

Genest, J.: "III. Clinical states associated with abnormal aldosterone excretion." *Can. Med. Assoc. J.* **77**: 780-785 (1957).

J7,341/57

Mental and emotional stress (especially anxiety states) as well as surgical operations can raise aldosterone production.

Birke, G., Dunér, H., Liljedahl, S. O., Pernow, B., Plantin, L. O., Troell, L.: "Histamine, catechol amines and adrenocortical steroids in burns." *Acta Chir. Scand.* **114**: 87-98 (1958). J10,862/58

In severely burned patients, blood and urinary histamine, EP and NEP content, as well as the excretion of corticoids (17-KGS) were considerably increased during the first twenty-four hours, but the duration of the rise varied according to the substances examined. Their role in the genesis of burn shock is discussed.

Marchbanks, V. H.: "Effect of flying stress on urinary 17-hydroxycorticosteroid levels. Observations during a 22½-hour mission." *J. Aviat. Med.* **29**: 676-682 (1958).

C58,431/58

Urinary "steroids were increased almost two-fold in the pilot" of a B-52 aircraft on a 22.5 hour nonstop flight from Florida to Argentina to New York. "The 17-OH-CS urinary output is a favorable index for measuring stress in flying personnel."

Euler, U. S. von, Gemzell, C. A., Levi, L., Ström, G.: "Cortical and medullary adrenal activity in emotional stress." *Acta Endocrinol. (Kbh.)* **30**: 567-573 (1959).

C66,890/59

Brief technical note on cortical and medul-

lary adrenal activity during emotional stress, based on new techniques of corticoid and catecholamine determinations.

Mason, J. W., Brady, J. V., Polish, E., Bauer, J. A., Robinson, J. A., Rose, R. M., Taylor, E. D.: "Patterns of corticosteroid and pepsinogen change related to emotional stress in the monkey." *Science* **133**: 1596-1598 (1961). D4,949/61

In rhesus monkeys, conditioned avoidance sessions of seventy-two hours caused an increase in 17-OHCS levels and an initial drop, followed by a prolonged, marked elevation in the pepsinogen concentration of the plasma.

Bugard, P.: "Etude hormonale et métabolique de la fatigue. II. Personnel volant à bord d'avions intercontinentaux" (Hormonal and metabolic study of fatigue. II. Crew members on intercontinental flights). *Ann. Endocrinol. (Paris)* **22**: 1008-1016 (1961).

D22,366/61

Hyperaldosteronism was more pronounced on jets than on conventional aircraft, and was definitely related to emotional tension. A decrease in 17-KS was evident in men but not in women. Excretion of 17-OHCS and creatinine was raised under the same conditions. Allegedly, endocrine-metabolic examinations can provide valuable early indices of fatigue among aviators.

Hyde, P. M., Skelton, F. R.: "Influence of stress on plasma and adrenal corticosterone levels in rats with intact and regenerating adrenals." *Endocrinology* **69**: 250-256 (1961). D9,289/61

"Rats with two regenerating adrenals responded to stress with higher peripheral plasma levels of corticosterone than did animals with one regenerating gland, but these values were always less than those of the controls."

Fukui, S.: "The influence of stress upon the excretion of adreno-cortical hormone in pulmonary tuberculosis. II." *Kekkaku* **37**: 125-129 (1962) (Japanese). J23,475/62

Elmadjian, F.: "Epinephrine, norepinephrine, and aldosterone: release and excretion." In: Schaefer, K. E., *Man's Dependence on the Earthly Atmosphere*, pp. 100-116. New York and London: Macmillan, 1962.

D30,946/62

Studies on EP and NEP secretion during stressful life situations in normal people and psychiatric patients "support the hypothesis

that active, aggressive, emotional displays are related to increased excretion of norepinephrine, whereas tense, anxious, but passive emotional displays are related to increased excretion of epinephrine." Aldosterone elimination was elevated in certain anxiety states without demonstrable increases in catecholamine excretion. The stressors examined were manipulation of the Hoagland-Werthessen pursuit meter, hockey, boxing, basketball, baseball and anxiety-inducing interviews.

Yates, F. E., Urquhart, J.: "Control of plasma concentrations of adrenocortical hormones." *Physiol. Rev.* **42**: 359-443 (1962).

D30,548/62

Very meticulous and detailed review of the literature on the stressors and feedback system responsible for corticoid concentrations in the plasma and tissues (727 refs.).

Hedner, P., Rerup, C.: "Plasma corticosteroid levels and adrenal ascorbic acid after intravenous corticotrophin injections and 'stressful' stimuli in the rat." *Acta Endocrinol. (Kbh.)* **39**: 527-538 (1962).

D21,246/62

In rats the increase in plasma corticoid levels unlike the depletion of adrenal ascorbic acid produced by ether anesthesia is blocked by dexamethasone. The corresponding effects of unilateral adrenalectomy are less readily influenced. Apparently, corticoids can only partially inhibit the stress-induced endogenous corticoid discharge. [Of course, if these feedback mechanisms were perfect during stress, the latter could never significantly increase corticoid production (H.S.).]

Arguelles, A. E., Ibeas, D., Ottone, J. P., Chekherdemian, M.: "Pituitary-adrenal stimulation by sound of different frequencies." *J. Clin. Endocrinol. Metab.* **22**: 846-852 (1962).

D28,851/62

In healthy young men, and even more markedly in anxious psychoneurotic patients, exposure to various pure sound frequencies for one-hour periods caused substantial elevations in 17-OHCS and 17-KGS excretion. "Adrenal cortical function in man may be remarkably sensitive to auditory stimulation, probably through the effect of ACTH released by intense sound."

Hedner, P.: "Adrenocortical activity studied by determining plasma corticosteroids. With special regard to the effect of exogenous corticotrophin." *Acta Endocrinol. (Kbh.)* **44** Supp. 86: 1-30 (1963).

E36,550/63

Monograph on the value of plasma corticoid determinations in assessing adrenocortical activity during stress.

Knigge, K. M., Hoar, R. M.: "A procedure for measuring plasma binding of adrenal corticoids; effect of acute and chronic stress." *Proc. Soc. Exp. Biol. Med.* **113**: 623-627 (1963).
E21,455/63

In guinea pigs and rats, the acute stressor effect of ether or pentobarbital anesthesia and the chronic stress of cold exposure markedly increase peripheral plasma corticoid levels; "the increment in corticoids during acute stress is predominately unbound, while the increment during chronic cold is associated with protein."

Pankov, Y. A.: "Some data on the changes of the adrenal cortex function in the animals during development of stress." *Probl. Endokrinol. Gormonoter.* **9** No. 6: 3-6 (1963) (Russian).
E33,281/63

Fazekas, I. G.: "Über die Mobilisierbarkeit des Corticosterongehaltes der 'Peripherischen Hormondepoten'" (On the mobilization of the corticosterone content of the 'peripheral hormone depot'). *Endokrinologie* **46**: 133-138 (1964) (44 refs.).

F16,013/64

Vecsei-Weisz, P., Kemény, V., Harangozó, M.: "Further investigations concerning functional changes in the adrenal cortex at the resistance stage of the general adaptation syndrome." *Acta Physiol. Acad. Sci. Hung.* **27**: 265-273 (1965).
G34,303/65

"The resistance stage of the general adaptation syndrome has been evoked in rats by the repeated administration of formalin, and the resulting functional changes were studied by the in vitro incubation of surviving adrenal slices. The aldosterone production was found to be augmented, the corticosterone production unaltered. After adding a progesterone precursor to the incubation medium the rate of production of corticosterone and aldosterone increased. The increase in aldosterone production after formalin treatment was equal to that in the controls. The increase in corticosterone synthesis was more pronounced in formalin-treated animals."

Blivaiss, B. B., Litta-Modignani, R., Galansino, G., Foa, P. P.: "Endocrine and metabolic response of dogs to whole body vibration." *Aerosp. Med.* **36**: 1138-1144 (1965).
F75,989/65

In dogs, horizontal whole body vibration produced an increase of plasma 17-OHCS and EP but not of 5-HT or NEP. This response persisted but was less severe under pentobarbital anesthesia.

Dörner, G., Stahl, F., Wendt, F., Schädlich, M.: "Beurteilung der Nebennierenrindefunktion beim Operationsstress durch fluormetrische Bestimmung von unkonjugiertem Kortisol und Kortikosteron im Plasma und Harn" (Evaluation of adrenal cortex function in surgical stress by fluorometric determination of unconjugated cortisol and corticosterone in plasma and urine). *Brun's Beitr. Klin. Chir.* **212**: 467-480 (1966).

G45,937/66

With an improved method for the fluorometric determination of unconjugated cortisol and corticosterone (11-OHCS), a distinct rise in blood and urine was noted. "The method easily allows to estimate quantitatively stress reactions of the hypothalamic-anterior lobe pituitary-suprarenal cortical system."

D'Amelio, G., Marchiori, C., Busonera, G., Celon, E.: "Modificazioni della eliminazione urinaria delle catecolamine dei 17-idrossicorticoidi e dei 17-ketosteroidi, nello stress da stimolazione vestibolare" (Changes in urinary elimination of catecholamines, 17-hydroxycorticosteroids and 17-ketosteroids in stress caused by vestibular stimulation). *Endocrinol. Sci. Cost.* **29**: 57-63 (1966).

J24,555/66

Sanchez, C., Miya, T. S., Bousquet, W. F.: "Effects of conditioning upon stress responses in the rat." *Proc. Soc. Exp. Biol. Med.* **123**: 615-618 (1966).

F73,973/66

Pretreatment of rats with small amounts of intravenous sodium chloride for five days inhibited the marked elevation of plasma corticosterone induced by saline in unpretreated controls. Similar pretreatment offered no protection, however, against the more pronounced stressor effect of intravenous histamine. The resting plasma corticosterone and ascorbic acid levels did not show any consistent seasonal variation, and there was no manifest relationship between the two values. This finding "suggests that caution be employed in relying upon adrenal ascorbic acid determinations as an index of adrenocortical activity or response to stressors."

Bridges, P. K., Jones, M. T.: "Personality, physique and the adrenocortical response to

a psychological stress." *Br. J. Psychiatry* **113**: 601-605 (1967). G47,391/67

In male medical students, plasma cortisol levels rose considerably during oral examinations.

Wegmann, H. M., Klein, K. E., Brüner, H.: "Die Auswirkung fliegerischer Belastung auf einige Blutkomponenten" (Effects of flying stress on certain components of the blood). *Int. Z. Angew. Physiol.* **23**: 293-304 (1967).

G45,957/67

Among the indicators examined in jet pilots training for Starfighter F-104 G flights, corticoids and certain enzyme activities in the blood proved most sensitive to stress, whereas other enzymes and blood sugar variations were unreliable (24 refs.).

Oyama, T., Takiguchi, M., Kudo, T., et al.: "Effects of halothane anesthesia and surgical operation on adrenocortical function." *Jap. J. Anesthesiol.* **16**: 361-368 (1967) (Japanese).

J24,054/67

In man, halothane anesthesia produces a rise in plasma corticoids that becomes more pronounced following surgical intervention.

Fazekas, I. G., Fazekas, A. T.: "Die Corticosteroid-Fraktionen des menschlichen Gehirns" (Corticosteroids and their derivatives in the human brain). *Endokrinologie* **51**: 183-210 (1967).

F86,025/67

Extensive studies on concentrations of various corticoids and their derivatives in different parts of the brain in normal people (accidental death) and in patients who suffered from alcoholism or chronically distressful diseases (37 refs.).

Hill, C. W., Fromm, P. O.: "Response of the interrenal gland of rainbow trout (*Salmo gairdneri*) to stress." *Gen. Comp. Endocrinol.* **11**: 69-77 (1968).

H2,458/68

Although very intense acute stressors raise plasma cortisol in rainbow trout, the effect of chronic low-level stress is transitory. Plasma cortisol levels "do not appear to be a useful indicator of the existence of chronic stressful conditions."

Oyama, T., Saito, T., Isomatsu, T., Samejima, N., Uemura, T., Arimura, A.: "Plasma levels of ACTH and cortisol in man during diethyl ether anesthesia and surgery." *Anesthesiology* **29**: 559-564 (1968).

G57,525/68

Mason, J. W., Jones, J. A., Ricketts, P. T., Brady, J. V., Tolliver, G. A.: "Urinary aldosterone and urine volume responses to 72 hr.

avoidance sessions in the monkey." *Psychosom. Med.* **30**: 733-745 (1968).

H6,461/68

"Urinary aldosterone levels showed marked fluctuations in relation to 72-hr. conditioned avoidance sessions in the monkey. Two different response patterns were observed. The first was a biphasic response characterized by an initial depression during avoidance, followed by a rebound elevation during the recovery period. The second was characterized by an elevation, in some cases quite marked, during avoidance with a return to basal level during the recovery period" (53 refs.).

Golikov, P. P., Popova, A. M.: "Corticosterone secretion and some indices of stress reaction." *Patol. Fiziol. Éksp. Ter.* **13** No. 1: 71-72 (1969) (Russian). J22,379/69

In rats, neither the corticosterone and ascorbic acid content of the adrenals nor the blood eosinopenia is an accurate indicator of the intensity of stress caused by restraint, but both do give approximations of it.

Winkler, G., Graef, V.: "Nachwirkungen einmaliger Nebennierenrindenstimulierung auf den Verlauf der Aldosteronausscheidung im Harn" (The effect of a single stimulation of the adrenal cortex on the course of urinary aldosterone excretion). *Z. Klin. Chem. Klin. Biochem.* **7**: 179-180 (1969). J22,932/69

In man, the stress of exhaustive muscular exercise increases aldosterone and potassium excretion as well as sodium retention, followed by a decrease in aldosterone and potassium elimination, which in turn initiates a rebound phenomenon. This cyclicity must be taken into account in evaluating pertinent information.

Plumpton, F. S., Besser, G. M.: "The adrenocortical response to surgery and insulin-induced hypoglycaemia in corticosteroid-treated and normal subjects." *Br. J. Surg.* **56**: 216-219 (1969). H9,868/69

In patients undergoing major surgery or experiencing insulin hypoglycemia, the concurrent administration of prednisolone usually, though not always, failed to cause the increase in plasma corticoids normally elicited by these stressors, but only for a limited length of time.

Lutwak, L., Whedon, G. D., Lachance, P. A., Reid, J. M., Lipscomb, H. S.: "Mineral, electrolyte and nitrogen balance studies of the Gemini-VII fourteen-day orbital space

flight." *J. Clin. Endocrinol. Metab.* **29**: 1140-1156 (1969). H16,831/69

Studies on two astronauts during two weeks of orbital space flight (NASA Gemini-VII) showed considerable individual variability of metabolic responses. "In one man, significant increases in urinary calcium occurred during the second week of flight, and persisted during the recovery phase; calcium balance became less positive in flight in both subjects. Urinary phosphate excretion increased substantially in flight in both subjects despite reduction in phosphate intake. Urinary nitrogen and sulfate excretion decreased in flight but less than would be expected from the reduction in intake. Patterns of excretion of magnesium, sodium, potassium and chloride were different for each subject and could in part be correlated with changes in adrenocortical steroid production. The principal hormonal change was a striking decrease during flight in the urinary excretion of 17-hydroxycorticosteroids."

Conroy, R. T. W. L., Elliott, A. L., Mills, J. N.: "Circadian rhythms in plasma concentration of 11-hydroxycorticosteroids in men working on night shift and in permanent night workers." *Br. J. Ind. Med.* **27**: 170-174 (1970). H24,017/70

Comparative studies were made of plasma corticoids in newspaper printing shop employees who regularly worked at night, and in engineering factory workers on monthly rotation shifts. Among the newspaper workers maximal concentrations were noted around 14:00 when they awoke, whereas the pattern was much more irregular in the engineering shift employees. "It appears that the adrenal cortical rhythm can be adapted to night work in a community in which this is universal, accepted and lifelong, but that such adjustment is unusual in men on night shift work for limited periods, and whose associates are mainly following a usual nyctohemeral existence."

Rubin, R. T., Rahe, R. H., Clark, B. R., Arthur, R. J.: "Serum uric acid, cholesterol and cortisol levels. Interrelationships in normal men under stress." *Arch. Intern. Med.* **125**: 815-819 (1970). G74,760/70

In healthy young U.S. Navy men undergoing underwater demolition training, physical and psychologic stress is associated with increases in serum uric acid, cholesterol and cortisol concentrations (34 refs.).

Katz, J. L., Weiner, H., Gallagher, T. F.,

Hellman, L.: "Stress, distress, and ego defenses. Psychoendocrine response to impending breast tumor biopsy." *Arch. Gen. Psychiatry* **23**: 131-142 (1970). G77,008/70

Women waiting for breast tumor biopsy showed widely different psychologic defense patterns and anxiety. The associated corticoid excretion also varied considerably, and was only roughly proportionate to the psychiatric score regarded as indicative of stress.

Golstein-Golaire, J., Vanhaelst, L., Bruno, O. D., Leclercq, R., Copinschi, G.: "Acute effects of cold on blood levels of growth hormone, cortisol, and thyrotropin in man." *J. Appl. Physiol.* **29**: 622-626 (1970).

G79,353/70

In man, a two-hour exposure to 4°C caused no change in plasma STH concentrations and only moderate variations in plasma cortisol, but TTH values rose as expected.

Takahashi, K., Daughaday, W. H., Kipnis, D. M.: "Regulation of immunoreactive growth hormone secretion in male rats." *Endocrinology* **88**: 909-917 (1971).

H37,347/71

Plasma immunoreactive STH rose more in gentled rats than in nongentled controls, whereas plasma corticosterone levels showed the opposite relationship. Pentobarbital anesthesia caused a significant rise in plasma STH in both gentled and nongentled rats and a corresponding decrease in plasma corticosterone. Ether, hypertonic glucose, 2-deoxyglucose, insulin and EP caused a marked suppression of plasma STH and an increase in plasma corticosterone; these changes were partly or totally blocked by pentobarbital anesthesia.

Brown, G. M., Schalch, D. S., Reichlin, S.: "Hypothalamic mediation of growth hormone and adrenal stress response in the squirrel monkey." *Endocrinology* **89**: 694-703 (1971). H45,128/71

In squirrel monkeys the stress of emotional excitement (chair restraint, capture) increased plasma STH and corticoid levels but the two changes did not run parallel. The STH response to capture and ether was blocked by small lesions in either the anterior or posterior ME, while adrenal responses to capture and chair restraint were blocked by lesions in the posterior ME. STH responses to ether were enhanced by midline optic chiasm lesions. However, great individual variations interfered with the precise evaluation of these data.

Coppen, A., Brooksbank, B. W. L., Noguera, R., Wilson, D. A.: "Cortisol in the cerebrospinal fluid of patients suffering from affective disorders." *J. Neurol. Neurosurg. Psychiatry* **34**: 432-435 (1971).

G90,735/71

The cortisol concentrations in the CSF of patients with depression or mania showed no significant differences.

Brown, G. M., Schalch, D. S., Reichlin, S.: "Patterns of growth hormone and cortisol responses to psychological stress in the squirrel monkey." *Endocrinology* **88**: 956-963 (1971).

H37,353/71

In squirrel monkeys, various stressors (capture, chair restraint, intense sound, aversive conditioning) increase plasma STH and cortisol levels, but the two responses are not parallel and presumably are regulated by diverse mechanisms. In the case of chair restraint, STH values fall to resting levels while cortisol continues to rise.

Lantos, C. P., Dahl, V., Basso, N., Cordero-Funes, J. R., Wassermann, G. F.: "A correlative study between adrenal function and the duration and intensity of an experimentally produced disease of adaptation." *J. Steroid Biochem.* **2**: 335-347 (1971).

G88,441/71

In rats, stress produced by repeated intramuscular injections of formaldehyde caused a particularly pronounced increase in the secretion of aldosterone, and to a lesser extent of corticosterone, into the adrenal vein blood. 18-OH-DOC discharge was less markedly raised, and was not as clearly correlated with the intensity and duration of stress as were the other two corticoids. Plasma renin concentrations diminished during stress. The authors believe that "the present results exclude the possibility that the increased aldosterone secretion was secondary to an augmented plasma angiotensin concentration."

Courtney, G. A., Marotta, S. F.: "Adrenocortical steroids during acute exposure to environmental stresses: I. Disappearance of infused cortisol." *Aerosp. Med.* **43**: 46-51 (1972).

J20,019/72

Courtney, G. A., Marotta, S. F.: "II. Uptake and release of infused cortisol by the hind limb of dogs." *Aerosp. Med.* **43**: 52-55 (1972).

J20,018/72

In dogs, the disappearance rate of infused cortisol was not very consistently affected by a variety of stressors.

Juráni, M., Mikulaj, L., Murgaš, K.: "Phylogenetic aspects of adrenocortical activity during the process of adaptation." *Adv. Exp. Med. Biol.* **33**: 619-629 (1972). J23,809/72

Bailey, R. E., Bartos, D., Bartos, F., Castro, A., Dobson, R. L., Grettie, D. P., Kramer, R., Macfarlane, D., Sato, K.: "Activation of aldosterone and renin secretion by thermal stress." *Experientia* **28**: 159-160 (1972). H54,154/72

Devlin, J. G., Varma, M. P. S., Kuti, J., O'Boyle, A.: "Studies on growth hormone release and cortisol with intravenous glucose loading." *Ir. J. Med. Sci.* **141**: 69-78 (1972). J19,599/72

Data on patients under extreme stress following myocardial infarction or major surgical interventions. "1. Growth hormone release is not readily suppressible by glucose in the stress situation studied. 2. Circulating catecholamines are probably not primarily involved in releasing excess growth hormone, as insulin release is more frequently elevated at the same time. 3. The paradoxical rise in glucose which can occur in extreme stress, appears to be a reversion to a primitive pattern of growth hormone secretion which is observed in the newborn infant. 4. The effect of glucose in adequately suppressing A.C.T.H. while producing statistically insignificant suppression of growth hormone releases, suggests either that the A.C.T.H. secreting cell is more sensitive to the direct effect of glucose, or that extra-pituitary factors, either neuronal or hormonal, may be of more significance in controlling growth hormone release."

Christison, G. I., Johnson, H. D.: "Cortisol turnover in heat-stressed cows." *J. Anim. Sci.* **35**: 1005-1010 (1972). J19,902/72

Stoeckel, H., Korpassy, A.: "Das Verhalten der Aldosteronexkretion und Hydrokortisonsekretion bei prolongiertem Stress und Langzeitbeatmung" (Investigations of hydrocortisone secretion and aldosterone excretion in patients with prolonged stress and long-term artificial respiration). *Z. Prakt. Anaesth.* **7**: 28-37 (1972). H65,375/72

In all of 11 intensive care patients with various diseases, aldosterone and cortisol secretion was increased for prolonged periods.

Leach, C. S., Alexander, W. C., Johnson, P. C.: "Adrenal and pituitary response of the

Apollo 15 crew members." *J. Clin. Endocrinol. Metab.* **35**: 642-645 (1972).

H61,627/72

"Inflight studies during the 14-day Gemini 7 mission showed increased urinary aldosterone excretion." Inflight specimens were not collected during the Apollo 15 mission, but when pre- and postflight levels were compared, postflight elevated excretion of urinary aldosterone was again manifest. "Increased secretion of this hormone could be one of man's adaptations to the weightless environment."

Rahe, R. H., Rubin, R. T., Gunderson, E. K. E.: "Measures of subjects' motivation and affect correlated with their serum uric acid, cholesterol, and cortisol." *Arch. Gen. Psychiatry* **26**: 357-359 (1972).

G90,674/72

Among trainees of a U.S. Navy Underwater Demolition Team, "predominantly positive correlations were seen between the subjects' serum uric acid levels and their estimates of their own motivation. Their serum cholesterol concentrations demonstrated consistently negative correlations with their motivational and pleasant affect scores. Highest correlations were positive ones found between the subjects' serum cholesterol levels and their unpleasant affect scores. Serum cortisol correlations with the three psychological criteria demonstrated wide variability around a zero correlation baseline."

Korpassy, A., Stoeckel, H., Vecsei, P.: "Investigations of hydrocortisone secretion and aldosterone excretion in patients with severe prolonged stress." *Acta Anaesthesiol. Scand.* **16**: 161-168 (1972). G97,967/72

Among patients in an intensive care unit for various reasons, as well as in normal post-operative patients, "excessive hyperaldosteronism and hypercortisolism were found in all of the cases, although the relationships between these hormones were variable."

Engquist, A., Winther, O.: "Variations of plasma cortisol and blood fibrinolytic activity during anaesthetic and surgical stress." *Br. J. Anaesth.* **44**: 1291-1297 (1972). J672/72

In man, during thirty to ninety-three minutes of surgical stress, "enhancement of fibrinolysis was significantly correlated with increase of plasma cortisol levels."

Hartley, L. H., Mason, J. W., Hogan, R. P., Jones, L. G., Kotchen, T. A., Mougey,

E. H., Wherry, F. E., Pennington, L. L., Ricketts, P. T.: "Multiple hormonal responses to graded exercise in relation to physical training." *J. Appl. Physiol.* **33**: 602-606 (1972). H79,757/72

In man the stress of heavy bicycle exercise increased plasma STH, cortisol and EP values but decreased insulin concentration.

Wise, L., Margraf, H. W., Ballinger, W. F.: "Adrenal cortical function in severe burns." *Arch. Surg.* **105**: 213-220 (1972).

G92,241/72

"Severely burned patients have prolonged high levels of free plasma cortisol and a decrease in plasma corticosteroid binding globulin... The sustained increase of 17-ketogenic steroids, as opposed to the rapid decrease of Porter-Silber chromogens, suggests that corticosteroids other than cortisol are secreted in larger than normal quantities, in response to the prolonged stress of severe burns" (22 refs.).

Brooksbank, B. W. L., Brammall, M. A., Cunningham, A. E., Shaw, D. M., Camps, F. E.: "Estimation of corticosteroids in human cerebral cortex after death by suicide, accident, or disease." *Psychol. Med.* **2**: 56-65 (1972). G97,911/72

The cortisol content of the frontal cerebral cortex of healthy individuals who had committed suicide was as low or lower than that of control patients who died suddenly without antecedent illness. "It is concluded therefore that neither the presumed severe emotional stress preceding suicide nor depressive illness itself is associated with high levels of cortisol in the cerebral cortex." On the other hand, in patients who died from stressful somatic diseases, brain cortisol was raised proportionately to the duration and severity of their physical illness.

Roussel, A., Daniel, J. Y., Assenmacher, I.: "Les glucocorticostéroïdes circulants du Lapin, et leurs fluctuations nyctémérales" (Circulating glucocorticoids and circadian variations in rabbits). *C.R. Acad. Sci. (Paris)* **277**: 341-344 (1973). J6,395/73

In rabbits, both plasma corticosterone and cortisol undergo circadian variations, with a peak during the day and a drop at the end of the night. However, the two corticoids do not show complete parallelism.

Kraus, M., Erdösová, R.: "Effects of chronic environmental stimulation on the activity of the rat adrenal cortex." In: Németh,

Š., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 129-141. Bratislava: Slovak Academy of Sciences, 1973. E10,463/73

In rats repeatedly submitted to the stress of nervous stimuli (for example, electroshock), corticosterone formation gradually decreases, whereas aldosterone and 18-OH-DOC become more conspicuous (30 refs.).

Hogan, R. P., Kotchen, T. A., Boyd, A. E., Hartley, L. H.: "Effect of altitude on renin-aldosterone system and metabolism of water and electrolytes." *J. Appl. Physiol.* **35**: 385-390 (1973). J5,657/73

In healthy young males, exposure to a simulated altitude of 12,000 ft. decreased plasma renin activity and urinary aldosterone excretion in proportion to the symptoms of acute mountain sickness that were manifested. It remains to be proven whether these changes are due to stress or to the specific effects of anoxia (45 refs.).

Turton, M. B., Deegan, T.: "Central and peripheral levels of plasma catecholamines, cortisol, insulin and non-esterified fatty acids." *Clin. Chim. Acta* **48**: 347-352 (1973). J8,031/73

In patients undergoing cardiac catheterization, elevations of EP, NEP, FFA and cortisol, and decreased levels of insulin are ascribed to stress. However, certain differences are noted in the concentration of these substances in various vascular territories.

Smith, G. P.: "Adrenal hormones and emotional behavior." *Prog. Physiol. Psychol.* **5**: 299-351 (1973). J11,271/73

Review mainly concerned with the role of catecholamines and corticoids in affecting or being produced by psychogenic stress (about 120 refs.).

Spat, A., Józán, S.: "Displacement analysis of aldosterone and corticosterone in the rat adrenal venous blood." *J. Steroid Biochem.* **4**: 509-518 (1973). J9,302/73

Simultaneous determination of aldosterone and corticosterone in the adrenal venous blood of rats is possible by means of a new technique. Even the mild stress of changing the environment caused consistent increases in corticosterone, but rises in aldosterone were only irregularly observed even after severe surgical stress.

Kraus, M., Erdösová, R.: "Effect of chronic stress on the production ofaldo-

sterone, 18-hydroxydeoxycorticosterone and corticosterone in rat adrenal glands." *Česk. Fysiol.* **22**: 469 (1973) (Czech).

Marple, D. N., Cassens, R. G.: "Increased metabolic clearance of cortisol by stress-susceptible swine." *J. Anim. Sci.* **36**: 1139-1142 (1973). J19,910/73

Rahe, R. H., Rubin, R. T., Arthur, R. J.: "The three investigators study. Serum uric acid, cholesterol, and cortisol variability during stresses of everyday life." *Psychosom. Med.* **36**: 258-268 (1974). J21,223/74

The authors studied their own responses to various life events. "Marked elevations in serum cholesterol were seen in one investigator throughout an unpleasant residential move; repeated peaks in serum cortisol were seen in one investigator during times of anguish and anger over personal disappointments and work changes. Two of the three men showed uric acid elevations into the 'gout range' prior to eagerly taking on a physical change. Occasionally, serum uric acid and cortisol values reached magnitudes previously reported as characteristic of men entering underwater demolition training and jumping into the ocean from hovering helicopters."

Ortiz, G. A., Argüelles, A. E., Crespin, H. A., Sposari, G., Villafaña, C. T.: "Modifications of epinephrine, norepinephrine, blood lipid fractions and the cardiovascular system produced by noise in an industrial medium." *Horm. Res.* **5**: 57-64 (1974).

H81,167/74

In aircraft factory workers exposed to turbine noise for three hours, there was generally a marked elevation of catecholamine excretion, blood cholesterol levels, FFA values, blood pressure and pulse frequency. Unexpectedly, the plasma corticoid concentrations were slightly subnormal, but this may have been due to circadian variations.

Follenius, M., Brandenberger, G.: "Influence de l'exercice musculaire sur l'évolution de la cortisolémie et de la glycémie chez l'homme" (Effect of muscular exercise on diurnal variations of plasma cortisol and

glucose in normal men). *Eur. J. Appl. Physiol.* **33**: 23-33 (1974). J16,058/74

In man, exercise on a bicycle ergometer raises plasma cortisol within ten minutes. Blood glucose decreases at first but is elevated to the initial level twenty minutes after cessation of work.

Fazekas, A. T. A.: "Konzentration und Verteilung von Cortisol in peripheren Geweben und Nebennieren unter physiologischen und pathophysiologischen Bedingungen" (Concentration and distribution of cortisol in peripheral tissues and adrenals under physiologic and pathophysiologic conditions), p. 346. Thesis, University of Ulm, 1974.

E10,669/74

Monograph on the cortisol content of the adrenals and various other tissues of guinea pigs as influenced by x-irradiation, pregnancy, age, corticoids, ACTH and so on. The distribution of radioactive cortisol in tissues plays a significant part in determining the blood level and excretion rate of the hormone during stress and after ACTH administration (394 refs.)

E10,668/74

Monograph on the distribution of twelve corticoids as determined by paper chromatography in the organs of rats, guinea pigs, dogs, cats and rabbits, showing great differences in their concentrations in the brain, heart, lungs, spleen, liver, kidney, muscles and adrenals. Special attention is given to the effect of various stressors and hormones on the metabolism and distribution of corticoids (numerous refs.).

Carroll, B. J., Heath, B., Jarrett, D. B.: "Corticosteroids in brain tissue." *Endocrinology* (In press). J20,878/

"A clear circadian variation of brain corticosteroid values was found in mice, together with a rapid elevation of the tissue levels in response to stress. Reduction of both plasma and tissue concentrations was observed after adrenalectomy and in response to dexamethasone treatment of mice. Between 24 and 48 hours *post mortem* mouse brain corticosteroid values decreased greatly." Brain areas not concerned with adrenocortical regulation contain particularly large amounts of corticoids.

Various Steroids

Urinary 17-KS may represent the metabolites of testoids or corticoids. Since it is often difficult to ascertain from the descriptions of the techniques used how the results should be interpreted, observations on the excretion of all these steroid metabolites will be presented here together. In general, it may be said that various stressors raise the excretion of corticoid, and decrease the elimination of testoid metabolites in consonance with the findings that adrenal function is increased while testicular activity is diminished during stress.

In man, 17-KS excretion exhibits circadian variations similar to those of corticoid elimination. In normal individuals, 17-KS excretion usually rises during the first three days after traumatic injury, but subsequently falls until convalescence. The rise is not observed in debilitated patients, probably because "due to a previous alarm, they are already in the stage of resistance or even approaching the stage of exhaustion." It was concluded that these findings support the concept that "alterations in adrenal cortical function are an integral part of the adaptation syndrome of Selye and a link in our understanding of the part this syndrome plays in clinical medicine." In these, as in many other studies, 17-KS excretion has obviously been considered to be characteristic of corticoid production, but this is not always justified. To properly evaluate alterations in testosterone secretion, it is best to measure blood or urinary testosterone itself, or its glucuronide. For example, under the influence of psychogenic stress, plasma testosterone is usually decreased.

Colonized squirrel monkeys showed elevated 17-OHCS but unchanged 17-KS and catecholamine excretion. The dominant animals had the highest 17-OHCS and the lowest catecholamine levels, whereas subordinate monkeys showed lower 17-OHCS and elevated catecholamine concentrations. The 17-KS level did not always parallel that of 17-OHCS. It is concluded that perhaps high corticoid production is necessary for the maintenance of dominance, but these results on primates differ from most studies on rodents in which other methods of dominance determination were used.

Various Steroids

(See also our earlier stress monographs, p. xiii)

Fraser, R. W., Forbes, A. P., Albright, F., Sulkowitch, H., Reifenstein, E. C.: "Colorimetric assay of 17-ketosteroids in urine. A survey of the use of this test in endocrine investigation, diagnosis, and therapy." *J. Clin. Endocrinol.* 1: 234-256 (1941).

A36,086/41

Depending upon the technique used, urinary 17-KS may represent androgen or corticoid metabolites. Various stressors lower the production of the former while raising that of the latter.

Forbes, A.: *The 17-Ketosteroid Excretion in Stress. Preliminary Report.* The Josiah Macy, Jr. Foundation Report. New York, 1942.

B27,227/42

Among four thousand patients with the most diverse types of stress-producing diseases, urinary 17-KS output was first enhanced and subsequently diminished.

Pincus, G.: "Studies of the role of the adrenal cortex in the stress of human subjects." *Rec. Prog. Horm. Res.* 1: 123-145 (1947). 98,426/47

Excellent review on the biochemical changes characteristic of the G.A.S. in man, with special reference to 17-KS excretion and blood count under the influence of circadian variations, the stresses of daily life, operating a Hoagland-Werthessen pursuit meter, flying and exposure to heat. The response of schizophrenics is abnormal in many respects, and the question is raised whether adrenal malfunction may play a pathogenic role in mental disease (20 refs.).

Forbes, A. P., Donaldson, E. C., Reifenstein, E. C. Jr., Albright, F.: "The effect of trauma and disease on the urinary 17-ketosteroid excretion in man." *J. Clin. Endocrinol.* **7**: 264-288 (1947). 98,825/47

In normal individuals, 17-KS excretion usually rises for about one to three days following injury and almost always falls later until convalescence is achieved. "In those debilitated patients where an alarm is not followed by a rise in 17-ketosteroids it is probable that, due to a previous alarm, they are already in the stage of resistance or even approaching the stage of exhaustion.... In chronically ill or debilitated individuals on the other hand, the initial level is subnormal and the response to injury usually small or absent. It is believed that these findings are further evidence that alterations in adrenal cortical function are an integral part of the adaptation syndrome of Selye and a link in our understanding of the part this syndrome plays in clinical medicine."

Pincus, G.: "Adrenal cortex function in stress." *Ann. N.Y. Acad. Sci.* **50**: 635-645 (1949). B37,780/49

General review of changes in adrenocortical function during stress and psychiatric illness. Special emphasis is placed upon blood sugar, blood lymphocytes, corticoids and 17-KS.

Zimmermann, W.: "Die Ausscheidung der 17-Ketosteroide im Harn als Methode zur Beurteilung der Nebennierenrindenaktivität" (Urinary 17-ketosteroid excretion as a method for the appraisal of adrenal cortex activity). *Klin. Wochenschr.* **29**: 371 (1951).

J6,106/51

Review on the value of urinary 17-KS determinations in the appraisal of clinical stress situations.

B73,567/53

Extensive review on clinical indices of adrenal responses to stress in man and the role of the G.A.S. in the pathogenesis of diseases of adaptation. Special emphasis is placed upon reactivity to infusions of ACTH, corticoids and EP, as well as upon the diagnostic value of blood eosinophils and 17-KS excretion, as indicators of adrenocortical participation in stress responses (47 refs.).

Kitay, J. I.: "Pituitary-adrenal function

in the rat after gonadectomy and gonadal hormone replacement." *Endocrinology* **73**: 253-260 (1963). E23,024/63

The pituitary-adrenal function during stress is partly dependent upon gonadal hormones, as shown by experiments on gonadectomized rats or those treated with male and/or female hormones. "Testosterone depressed ACTH secretion and steroid clearance but increased adrenal responsiveness to ACTH, whereas estradiol exerted a consistently stimulatory effect."

Mason, J. W., Taylor, E. D., Brady, J. V., Tolliver, G. A.: "Urinary estrone, estradiol, and estriol responses to 72-hr. avoidance sessions in the monkey." *Psychosom. Med.* **30**: 696-709 (1968). H6,458/68

"Urinary estrone, estradiol and estriol all show a similar biphasic response to 72-hr. conditioned avoidance sessions in the monkey, characterized by a decline in levels during avoidance, usually followed by a rebound elevation in the recovery period" (40 refs.).

Mason, J. W., Tolson, W. W., Robinson, J. A., Brady, J. V., Tolliver, G. A., Johnson, T. A.: "Urinary androsterone, etiocholanolone, and dehydroepiandrosterone responses to 72-hr. avoidance sessions in the monkey." *Psychosom. Med.* **30**: 710-720 (1968).

H6,459/68

"Urinary androsterone, etiocholanolone, and dehydroepiandrosterone levels show substantial responses in association with 72-hr. avoidance sessions." In most cases, there is a biphasic response characterized by a decline during avoidance, followed by a rebound elevation during recovery.

Mason, J. W., Kenion, C. C., Collins, D. R., Mougey, E. H., Jones, J. A., Driver, G. C., Brady, J. V., Beer, B.: "Urinary testosterone response to 72-hr. avoidance sessions in the monkey." *Psychosom. Med.* **30**: 721-732 (1968). H6,460/68

In association with seventy-two hour avoidance sessions there is an initial decrease of urinary testosterone during avoidance followed by a rebound elevation during the recovery period (25 refs.).

Rose, R. M.: "Androgen responses to stress. I. Psychoendocrine relationships and assessment of androgen activity." *Psychosom. Med.* **31**: 405-417 (1969). G70,682/69

17-KS have often been used as an indication of androgen secretion during stress. However, this test is unreliable because

glucocorticoids may also be metabolized to 17-KS. "To properly evaluate alterations in testosterone secretion, which is the most potent of androgens, it is best to measure blood or urinary production rates. It is also possible to measure the excretion of testosterone glucuronide to evaluate the possible inhibition of testosterone secretion during exposure to potential stress."

Matsumoto, K., Takeyasu, K., Mizutani, S., Hamanaka, Y., Uozumi, T.: "Plasma testosterone levels following surgical stress in male patients." *Acta Endocrinol.* (Kbh.) **65**: 11-17 (1970). H30,322/70

In man, plasma testosterone decreased after surgical interventions but returned to normal by the sixth postoperative day.

Wise, L., Margraf, H., Ballinger, W. F.: "The effect of surgical trauma on the excretion and conjugation pattern of 17-ketosteroids." *Surgery* **71**: 625-630 (1972). G89,558/72

Aono, T., Kurachi, K., Mizutani, S., Hamanaka, Y., Uozumi, T.: "Influence of major surgical stress on plasma levels of testosterone, luteinizing hormone and follicle-stimulating hormone in male patients." *J. Clin. Endocrinol. Metab.* **35**: 535-542 (1972). H59,966/72

Leshner, A. I., Candland, D. K.: "Endocrine effects of grouping and dominance rank in squirrel monkeys." *Physiol. Behav.* **8**: 441-445 (1972). G90,599/72

17-OHCS, 17-KS and total catecholamine excretions were used as indices of social stress in colonized and isolated squirrel monkeys. "Compared to the isolated animals, the colonized monkeys showed elevated 17-OHCS but unchanged catecholamine and 17-KS levels. In the colonized group the dominant animals had the highest 17-OHCS levels and the lowest catecholamine levels, while the subordinate animals showed lower 17-OHCS levels and elevated catecholamine levels. 17-KS levels were related to dominance rank by a J-shaped function." Presumably, high adrenocortical output is necessary for the maintenance of dominance. These results on primates differ from most studies on rodents which use other methods to determine dominance.

Kreuz, L. E., Rose, R. M., Jennings, J. R.: "Suppression of plasma testosterone levels

and psychological stress." *Arch. Gen. Psychiatry* **26**: 479-482 (1972).

G89,651/72

Among young officer candidates, plasma testosterone was decreased during the "stressful part of the course."

Carstensen, H., Amér, I., Wide, L., Amér, B.: "Plasma testosterone, LH and FSH during the first 24 hours after surgical operations." *J. Steroid Biochem.* **4**: 605-611 (1973). J10,319/73

In patients, plasma LH and testosterone decreased four to five hours after surgery. LH subsequently returned to normal, whereas testosterone remained low over the twenty-four-hour observation period. No change in plasma FSH was noted.

Daly, J. R., Evans, J. I.: "Daily rhythms of steroid and associated pituitary hormones in man and their relationship to sleep." *Adv. Steroid Biochem. Pharmacol.* **4**: 61-110 (1974). J15,152/74

Detailed review on the function of the hypothalamo-pituitary-adrenal axis in man during sleep, with a description of the methodology for EEG measurement of sleep and a periodic obtention of blood specimens by means of an intravenous catheter throughout the night. The plasma corticoids drop gradually from a zenith at 08:00 to a nadir at midnight. The circadian rhythm of plasma testosterone has been less carefully studied but appears to run parallel to that of cortisol; however, unlike the latter, it cannot be inhibited by dexamethasone. The circadian variations of FSH and LH likewise receive comparatively little attention, but sleep-related rises in LH secretion are regularly observed during adolescence. There are two phases of cortisol elimination, "basal" and "impulsive"; only the latter shows an early morning peak sensitive to corticoid inhibition (about 220 refs.).

Howland, B. E., Beaton, D. B., Jack, M. I.: "Changes in serum levels of gonadotropins and testosterone in the male rat in response to fasting, surgery and ether." *Experientia* **30**: 1223-1225 (1974). H98,258/74

Rose, R. M., Bernstein, I. S., Gordon, T. P.: "Consequences of social conflict on plasma testosterone levels in rhesus monkeys." *Psychosom. Med.* **37**: 50-61 (1975). J23,314/75

ACTH

In comparison with the vast literature on the corticoid content of blood and urine during stress, there is relatively little on plasma ACTH. Few investigators have made accurate ACTH determinations in the plasma because the necessary technology is somewhat complicated. However, available data merely confirm what could be expected, namely, that whenever there is evidence of increased corticoid secretion, the ACTH content of the plasma is also high.

Even the first observations in rats have shown that the response of the pituitary is extremely rapid. As soon as two minutes after application of stressors, there is a definite rise in plasma ACTH. This is particularly pronounced after adrenalectomy, which in itself suffices to cause an ACTH discharge by eliminating the corticoid feedback mechanism.

Various stressors (sound, histamine, cold, pain) differ in the intensity and speed of the ACTH discharge that they provoke in rats, but essentially their effects are quite comparable. Ether first augments, then inhibits ACTH release, whereas pentobarbital exerts only an inhibitory effect. The suppression by anesthetics and sedatives has been ascribed to a depression of the brain stem reticular system activity.

In patients exposed to various stressors, especially surgical trauma, radioimmuno-logic assays revealed an almost tenfold increase in plasma ACTH with relatively brief peaks, which can easily be missed in the event of single determinations.

In man, the ACTH (radioimmunoassay) concentration of the plasma is highest in the evening and lowest in the morning. The reverse is true in the rat, presumably because it is a nocturnal animal, and thus its activity cycle is opposite to that of man.

Normally, the ACTH content of the CSF parallels that of the plasma, but following the stress of pneumoencephalography, the plasma ACTH content rises, whereas that of the CSF remains normal, suggesting that the transfer from plasma to CSF is slow.

ACTH

(See also our earlier stress monographs, p. xiii)

Sydnor, K. L., Sayers, G.: "Blood and pituitary ACTH in intact and adrenalectomized rats after stress." *Endocrinology* **55**: 621-636 (1954). B99,016/54

Two minutes after application of stressors in rats, there is a rapid increase in the ACTH content of the blood but not in that of the pituitary. Adrenalectomy enhances the increase in ACTH caused by stressors.

Royce, P. C., Sayers, G.: "Blood ACTH: effects of ether, pentobarbital, epinephrine and pain." *Endocrinology* **63**: 794-800 (1958). C61,941/58

In rats, painful stimuli markedly elevate blood ACTH within a few minutes. "Ether first excites, then inhibits ACTH release. Pentobarbital exhibits only a depressant action. The excitatory action of ether is blocked by decerebration and by destruction

of the median eminence area of the hypothalamus. The excitatory action of epinephrine is manifest in the decerebrate but not in the median eminence lesioned rat. Since ether and pentobarbital depress the brain stem reticular system, it is reasonable to speculate that the action of these two agents in inhibiting ACTH release involves this multi-synaptic conduction system."

Rochefort, G. J., Rosenberger, J., Saffran, M.: "Depletion of pituitary corticotrophin by various stresses and by neurohypophysial preparations." *J. Physiol.* **146**: 105-116 (1959). C67,709/59

In rats, various stressors (sound, histamine, cold) differ in the intensity and speed with which they deplete the anterior or posterior pituitary of its ACTH content; hence the differentiation between "neurogenic" and "systemic" stressors appears to be justified. CRF causes a prompt and sustained fall in the ACTH content of the anterior pituitary

with only a momentary dip at sixty minutes in the posterior lobe. Commercial and synthetic vasopressin preparations are less effective than CRF; hence, the latter is assumed to be the physiologic releasing substance. Pretreatment with cortisol decreases but does not abolish the sensitivity of the anterior lobe to CRF.

Holub, D. A., Kitay, J. I., Jailer, J. W.: "Alteration of pituitary ACTH secretion in rats after injection and handling." *Endocrinology* **65**: 968-971 (1959).

Yalow, R. S., Varsano-Aharon, N., Echendemia, E., Berson, S. A.: "HGH and ACTH secretory responses to stress." *Horm. Metab. Dis.* **1**: 3-8 (1969).

H12,001/69

In man, electroshock therapy was always followed by an abrupt rise in plasma ACTH, but without significant alterations in STH release. Histalog, an analogue of histamine, caused an elevation of plasma STH twenty to thirty minutes after the increase in plasma ACTH. "Dissociation of ACTH and growth responses to these stimuli as well as to surgery and vasopressin suggests that the two hormones are not discharged through a common pathway responding in a nondiscriminatory fashion to all noxious stimuli. The secretory response of growth hormone to a variety of stimuli characterized by carbohydrate deficit, established in previous studies, seems to be independent of pathways responding generally to 'stress.'"

Matsuyama, H., Ruhmann-Wennhold, A., Nelson, D. H.: "Radioimmunoassay of plasma ACTH in intact rats." *Endocrinology* **88**: 692-695 (1971).

H36,540/71

In rats, which are most active at night, the ACTH (radioimmunoassay) content of the plasma was higher between 18:00 and 03:00 than between 08:00 and 12:00. This is the opposite of the circadian pattern in man. Metyrapone increased plasma ACTH after two to eight hours. Five minutes after ex-

posure to stress even more pronounced rises were observed.

Newsome, H. H., Rose, J. C.: "The response of human adrenocorticotrophic hormone and growth hormone to surgical stress." *J. Clin. Endocrinol. Metab.* **33**: 481-487 (1971). H45,875/71

Observations on patients who have undergone various forms of surgery suggest that STH and ACTH plasma levels rise in a parallel fashion and are presumably mediated through a common afferent pathway in the spinal cord.

Matsuyama, H., Ruhmann-Wennhold, A., Johnson, L. R., Nelson, D. H.: "Disappearance rates of exogenous and endogenous ACTH from rat plasma measured by bioassay and radioimmunoassay." *Metabolism* **21**: 30-35 (1972). H50,163/72

H52,549/72

In rats, noise, vibration, ether, cold, insulin, pentylenetetrazol, amphetamine and 2-D-deoxyglucose caused a rise in plasma corticosterone with a corresponding fall in STH. Gentling or administration of pentobarbital lowers corticosterone and increases STH in plasma. The results are interpreted as indicating an inverse relationship between ACTH and STH secretion that is in accordance with the "pituitary-shift" theory.

Nelson, D. H., Ruhmann-Wennhold, A.: "The assay of ACTH in plasma." *Mt. Sinai J. Med.* **40**: 315-322 (1973). J3,809/73

Description of a sensitive and accurate radioimmunoassay of ACTH in plasma which revealed an almost tenfold increase in patients exposed to various stressors, particularly surgical trauma. However, the peaks are relatively short and may readily be missed in single determinations. The circadian variations generally show a peak around 06:00.

Kendall, J. W., McGilvra, R., Lamorena, T. L.: "ACTH in cerebrospinal fluid and brain" (abstracted). *Program 55th Ann. Meeting Endocr. Soc.*, p. A-78. Chicago, 1973. H72,960/73

Previous reports have indicated that ACTH is present in the CSF of unstressed men in approximately the same concentration as in plasma. The stress of pneumoencephalog-

rathy causes a pronounced rise of ACTH in plasma but not in CSF, suggesting that transport from plasma into the CSF is slow.

STH (Somatotrophic or Growth Hormone)

Hypoglycemia is a potent stimulus for STH secretion, and hence, stressors (for example, insulin) that cause a fall in blood sugar increase the plasma STH level in various species, including man. This response is inhibited by glucocorticoids.

On the other hand, the plasma STH levels are suppressed by glucose administration and subsequently rise as the blood glucose diminishes even without there being actual hypoglycemia. Stressors (for example, fasting, exercise) likewise inhibit the glucose-induced STH secretion, perhaps because of accelerated sugar utilization.

The response to stress is dependent on numerous conditioning factors. However, under ordinary conditions, a variety of stressors (insulin, fasting, muscular exercise, anesthesia during surgery, electroconvulsive therapy, emotional stress, pyrogens) increase plasma STH in man. At the same time, plasma FFA levels rise, even without any change in plasma insulin. Presumably, STH discharge is at least partly responsible for the mobilization of readily oxidizable FFA to satisfy the increased energy requirements during stress.

In one carefully conducted study, the stress of arterial catheterization caused a rise in the serum immunoreactive STH in man, but infusion of NEP and a cold pressor test failed to duplicate this response. Plasma STH often rises during periods of muscular work, while insulin values remain unchanged or even decrease. The failure of plasma insulin to rise in response to stress-induced hyperglycemia is consistent with the finding that EP infusion impairs insulin discharge. Possibly, certain stressors are diabetogenic, not only because of EP and corticoid release, but also because of an STH discharge combined with EP-induced suppression of insulin secretion.

According to some investigators, in man, the acute stress of electroshock is less active in causing STH secretion than are stressors with long-lasting effects (for example, physical or mental trauma, endotoxins). The selective suppression of STH secretion by dexamethasone does not interfere with STH production during insulin hypoglycemia. This finding further supports the view that the secretion of the two hormones is relatively independent.

Endotoxin usually elevates ACTH and STH levels almost simultaneously in the plasma of man. However, in rats, there is no strict parallelism between ACTH and STH release during stress, perhaps because of different thresholds of stimulation or

different pathways through which the secretion of these hormones can be differentially regulated. In any event, the dissociation between STH and ACTH (or glucocorticoid) secretion has been demonstrated following exposure to a variety of stressors. Thus, heat raises serum STH in man much more readily than it does the glucocorticoid level. Similar observations were made on U.S. marines injured in battle. Here again, a rise in plasma STH proved to be a more constant manifestation of stress than the elevation of plasma cortisol.

Despite certain above-mentioned exceptions, in general the stress-induced STH discharge parallels ACTH and glucocorticoid secretion, and since animal experiments have shown that the latter can be blocked by hypothalamic or infundibular lesions, it is presumably mediated through the CNS. Yet the fact that STH and ACTH secretion can be elicited independently of each other confirms that release of the two hormones is not mediated through the same mechanism. The same is true of LTH whose secretion is likewise often, but not always, parallel to that of STH during stress. For example, in nursing women, plasma LTH may rise considerably without any associated increase in STH production.

In patients undergoing surgery and receiving morphine (in connection with anesthesia), plasma cortisol and STH rises were largely blocked, but adrenocortical responsiveness to exogenous ACTH was maintained.

The STH content of human fetal plasma rises during the stress of delivery and this response may prevent neonatal hypoglycemia.

Serum STH is greatly increased in man following ingestion of L-dopa (a precursor of dopamine) whereas chlorpromazine (an antiadrenergic drug) depresses the STH level.

There is some evidence that STH secretion is stimulated both by dopaminergic and by serotonergic pathways. In any event, in the rat and in man, 5-HT antagonists, such as cyproheptadine, or the pineal hormone melatonin, can inhibit STH release.

Most of the studies on STH secretion during stress have been performed in man and the rat. However, it has also been demonstrated that in pigeons there is a definite circadian cycle of plasma STH which reaches a peak at 06:00 and a low point at 18:00.

The rhesus monkey has been most extensively used for studies on stress-induced STH secretion. In this species, intravenous lysine-vasopressin increased plasma STH, but so did a variety of other stressors, such as pain, hemorrhage, surgical trauma, conditioned avoidance sessions and allegedly, even chlorpromazine. In squirrel monkeys, rises in plasma STH and cortisol were observed after capture, chair restraint, intense sound, and aversive conditioning, but the two responses were not parallel.

Much less attention has been given to the effect of stress upon the STH content of the pituitary. Usually, formaldehyde injections and ringing of a doorbell raised pituitary STH, while cold depleted it. Fasting caused a biphasic reaction according to one group of investigators, whereas others found that starvation for four days progressively depleted the STH content of the rat adenohypophysis. Such a depletion has also been noted after treatment with EP, vasopressin, cold or insulin. Although individual reports differ, depending upon the intensity and the duration of the stress applied, it may be said that in general the pituitary STH content decreases as the plasma level rises, as might be expected in the event of its discharge from the gland at a rate which cannot be easily compensated for by resynthesis.

To summarize the many contradictory reports just surveyed, the bulk of evidence

supports the view that a rise in blood glucose (produced by administration of glucose or catecholamines) is associated with a decrease in STH secretion, whereas hypoglycemia (induced by fasting or insulin) exerts an opposite effect.

Although, in general, stress produces an increased discharge of both STH and ACTH, their rates of release are not necessarily parallel. This fact as well as the identification by electrolytic lesions of separate centers regulating the discharge of ACTH and STH show that their production during stress is not strictly interdependent.

It also appears well established that, as a rule, an increase in plasma STH is associated with a decreased concentration of this hormone within the adenohypophysis. This finding may be expected if we agree that, normally, a discharge of STH from the gland into the blood is not easily compensated for by rapid resynthesis.

Evidently, depending upon experimental conditions (nutritional status, species differences, severity of stress, associated specific effects and intensity of the eliciting agent), stress may activate or inhibit some of the many regulating mechanisms more or less selectively. This explains why the results are not always identical, but in general it may be concluded that a discharge of STH is characteristic of the stress response.
