hypothalamic lesions exerted only a partial inhibition of the compensatory adrenal hypertrophy, whereas in our experience median eminence lesions completely inhibit the hypertrophy of the remaining adrenal gland. It is likely that in McCann's experiments the production of the CRF was not entirely inhibited and that consequently hydrocortisone caused a further block of the CRF release."

Egdahl, R. H., Irons, G., Jackson, B. T.: "Pituitary ACTH release in dogs with removal of hypothalamus and higher CNS structures." *Fed Proc.* 18: 41 (1959).

J10,795/59

The authors' earlier experiments showed that removal of the brain down to the hypothalamus does not prevent the maximal release of ACTH following operative trauma. Now it has been demonstrated that if the hypothalamus is removed in addition to the cerebral cortex, hippocampus and thalamus (brain stem intact below the level of the inferior colliculus), the resting 17-OHCS values of adrenal venous blood are increased and will rise even higher after burns. [Histologic examination showed remnants of ME in at least some animals (H.S.).] It is concluded that the pituitary can be activated to secrete ACTH even in the absence of the hypothalamus and higher CNS structures. Dogs with these operations have high resting adrenal corticoid outputs which "could be due to the removal of high CNS inhibition of ACTH release from the pituitary. This would leave a pituitary remarkably sensitive to previously inhibited stimuli. It is possible that intact dogs with hypothalamic lesions fail to show adrenal cortical responses to trauma because of unopposed higher CNS inhibition of pituitary ACTH release."

Knigge, K. M., Penrod, C. H., Schindler, W. J.: "In vitro and in vivo adrenal corticosteroid secretion following stress." *Am. J. Physiol.* 196: 579-582 (1959).

C65,769/59

In rats, scalding or restraint produces an initial biphasic response in ACTH and corticosterone secretion in which the drop is not due to adrenal exhaustion since it occurs at the time when the pituitary contains approximately twice the normal amount of ACTH. "The low level of hormone secretion was replaced by very high levels by treatment of the stressed rat with reserpine or by placement of hypothalamic lesions. At a variable time after stress, corresponding to time of least corticosteroid secretion, there

appears to exist an inability of the pituitary to release ACTH, which may be due to cessation of the initial hypothalamic stimulation or to a neural mechanism which temporarily suppresses or inhibits the secretion of endogenous ACTH."

Kovács, S., Lissák, K., Endrőczi, E.: "Effect of the lesion of paraventricular nucleus on the function of the pituitary, thyroid, adrenal cortex and gonadal systems." *Acta Physiol. Acad. Sci. Hung.* **15**: 137-144 (1959). C72,311/59

In rats, lesions of the paraventricular nucleus decreased the corticoid content of the adrenals. This was interpreted as an indication of adrenal hyperactivity.

Winkler, G., Blobel, R., Tonutti, E.: "17-OH-Corticoidausscheidung bei Meerschweinchen mit Läsionen im mittleren Hypothalamus" (The effect of lesions in the middle region of the hypothalamus on 17-OH-corticoid excretion in guinea pigs). *Acta Neuroveg. (Wien)* **20**: 230-237 (1959). C76,659/59

Smelik, P. G., Bouman, P. R., Wied, D. de: "Influence of hypothalamic lesions on compensatory adrenal hypertrophy." *Acta Physiol. Pharmacol. Neerl.* **8**: 515 (1959). D91,593/59

In rats, destruction of the ME diminished the compensatory hypertrophy of the remaining adrenal following unilateral adrenalectomy. Extensive bilateral lesions in the anterior or posterior hypothalamus did not produce this effect.

Halász, B., Szentágothai, J.: "Histologischer Beweis einer nervösen Signalübermittlung von der Nebennierenrinde zum Hypothalamus" (Histologic evidence of nervous signals from the adrenal cortex to the hypothalamus). *Z. Zellforsch. Mikrosk. Anat.* **50**: 297-306 (1959). J13,010/59

In rats, exposure to stress (formalin) or ACTH causes shrinkage of the nucleus ventromedialis in the hypothalamus with concurrent adrenocortical hypertrophy. Cortisone, adrenalectomy or denervation of the adrenals has an inverse effect. Unilateral adrenalectomy induces nuclear swelling only in the contralateral nucleus ventromedialis. Presumably, the latter receives nervous signals from the contralateral adrenal cortex that may affect its function.

Harris, G. W.: "Central control of pituitary secretion." In: Magoun, H. W., *Hand-*

book of Physiology. Section I. Neurophysiology, Vol. 2, pp. 1007-1038. Washington, D.C.: American Physiological Society, 1960 (366 refs.). E7,322/60

Sayers, G.: "Hypothalamus and adenohypophysis: with special reference to corticotrophin release." *Acta Endocrinol. (Kbh.)* **50** Supp.: 25-31 (1960). C92,384/60

Dear, W. E., Guillemin, R.: "Adrenal sensitivity to ACTH as a function of time after hypothalamic lesion and after hypophsectomy." *Proc. Soc. Exp. Biol. Med.* **103**: 356-358 (1960). C81,326/60

After hypophsectomy or lesion of the ME, sensitivity to ACTH gradually decreases. Hence, it is desirable to use only animals recently operated on for the testing of CRF.

Moll, J.: "Localization of hypothalamic lesions inhibiting adrenal weight maintenance in the rat." *Acta Endocrinol. (Kbh.)* **34**: 19-26 (1960). C84,933/60

An attempt was made to find the center responsible for the maintenance of adrenal weight. Following lesions in the antero-basal and mid-basal hypothalamus the weights of both adrenals were subnormal. Compensatory adrenal hypertrophy was only slightly inhibited by the lesions. Lesions destroying the pituitary stalk and lesions in the median eminence, had no effect on adrenal weight."

D'Angelo, S. A.: "Hypothalamus and endocrine function in persistent estrous rats at low environmental temperature." *Am. J. Physiol.* **199**: 701-706 (1960). C94,846/60

In rats, preoptic and anterior hypothalamic lesions caused persistent estrus and pituitary hypertrophy. Serum TTH, thyroid histology and the ascorbic acid concentration in the adenohypophysis and adrenal remained normal. Exposure to cold caused ovarian atrophy, uterine involution, cessation of estrus and inhibition of the pituitary hypertrophy otherwise noted after the lesions. Despite adrenal enlargement, plasma corticosterone levels in the lesioned rats exposed to cold averaged less than one-third those of controls, and adrenal ascorbic acid concentration remained normal. Presumably, "hypothalamic lesions which permit adequate trophic hormone secretion at normal temperatures drastically curtail thyroidal and ovarian function and selectively limit adrenal responses in the cold."

Endrőczi, E.: "Contributions to the hypothalamic control of pituitary, ovarian and

adrenal cortical function." *Acta Physiol. Acad. Sci. Hung.* 18: 301-307 (1961).

E57,282/61

In rats, electrocoagulation of the anterior hypothalamic area, between the periventricular nucleus optic chiasma and infundibulum extending into the preoptic region, increased uterine weight and induced continuous estrus. ACTH secretion (corticoid level of adrenal venous blood) was augmented. The gonadal changes were enhanced by adrenalectomy but prevented by ovariectomy. It is concluded, "the adrenocortical reaction to the hypothalamic lesion is due to a primarily increased ovarian activity, and that adrenocortical secretion very probably lessens the gonadal changes appearing after hypothalamic lesion."

Ahrén, C.: "The effect of hypothalamic lesions on acute and chronic stress reaction." *Acta Pathol. Microbiol. Scand.* 51 Supp. 144: 145-149 (1961). B46,032/61

Summary of an oral presentation of experiments on rabbits given repeated injections of formaldehyde which indicate that "experimental animals with lesions in the premammillary posterior of the hypothalamus lose their ability to react with an adrenal hyperplasia during chronic stress, while experimental animals with lesions in the corpora mamillaria react with an accentuated adrenal hyperplasia." An acute alarm reaction causes intense lymphopenia within three hours, but this response is not prevented by lesions in the premammillary region or in the corpora mamillaria. "Judging by these partly preliminary results, it appears that different parts of the hypothalamus are engaged in on the one hand the chronic stress reaction and on the other hand the acute alarm reaction. It also appears probable that different parts of the hypothalamus are engaged in the development of the complete adaptation syndrome."

Moll, J., Wied, D. de, Kranendonk, G. H.: "Observations on the thyroid-adrenal relationship in rats with hypothalamic lesions." *Acta Endocrinol. (Kbh.)* 38: 330-340 (1961). D13,092/61

In rats, electrocoagulation of the hypothalamic area between the fornix and the paraventricular nuclei induces adrenal atrophy and decreases corticoid secretion without preventing the adrenal response to stressors.

Halász, B., Pupp, L., Uhlarik, S.: "Hypo-

physiotrophic area in the hypothalamus." *J. Endocrinol.* 25: 147-154 (1962).

D38,273/62

Adenohypophyseal tissue of thirty-day-old rats was transplanted into different regions of the hypothalamus of adult recipients. Grafts in the ventral hypothalamus retained a normal histologic appearance despite lack of contact with the ME. A "hypophysiotrophic" area was detected by the location of basophils in the graft and the maintenance of the target organs for anterior lobe hormones, except that the gonads sometimes underwent atrophy. Grafts in other sites did not maintain their structure or preserve the integrity of the target glands.

D20,306/62

In dogs, electric stimulation of sixty-six points in the hypothalamus and adjacent parts of the brain resulted in increased catecholamine and 17-OHCS secretion from certain regions, but the two responses were not necessarily correlated.

Brodish, A.: "Diffuse hypothalamic system for the regulation of ACTH secretion." *Endocrinology* 73: 727-735 (1963).

E35,524/63

In rats, plasma-corticosterone increases in response to ether stress were impeded "following placement of a small lesion in almost any region at the base of the hypothalamus between the optic chiasm and the mammillary bodies." Larger lesions produced even more severe, but never complete suppression of ACTH discharge. The results are interpreted as indicating that "the entire region of the ventral hypothalamus extending from the optic chiasm to the mammillary bodies is involved in ACTH secretion and that a diffuse hypothalamic nucleus or network exists for the control of ACTH secretion rather than a localized discrete center."

E3,687/63

Review on the hypothalamic regulation of all adenohypophyseal hormones, with only one section devoted to stress and ACTH (more than 200 refs.).

Snyder, J., D'Angelo, S. A.: "Hypothalamic stimulation and ascorbic acid content of endocrine glands of the albino rat." *Proc. Soc. Exp. Biol. Med.* **112**: 1-4 (1963).

D54,492/63

In rats, electric stimulation of the preoptic and anterior hypothalamic areas causes adrenal hypertrophy and corpus luteum formation.

Endrőczi, E., Lissák, K.: "Effect of hypothalamic and brain stem structure stimulation on pituitary-adrenocortical function." *Acta Physiol. Acad. Sci. Hung.* **24**: 67-77 (1963). E32,622/63

In cats with electrodes chronically implanted in different hypothalamic structures, "stimulation of the basal septum, antero-lateral hypothalamus and lateral hypothalamus inhibits adrenocortical secretion. No significant change resulted from the stimulation of the supraoptic and paraventricular nuclei. Secretion increased markedly in response to the stimulation of the posterior tuber, premammillary region, mesencephalic reticular formation, and ventral tegmentum. Stimulation of the dorsal tegmentum at the level of the superior colliculus caused inhibition."

D'Angelo, S. A., Snyder, J., Grodin, J. M.: "Electrical stimulation of the hypothalamus: simultaneous effects on the pituitary-adrenal and thyroid systems of the rat." *Endocrinology* **75**: 417-427 (1964). F20,067/64

In rats, the mere presence of electrodes in the medial ventral hypothalamus had no effect on TTH secretion, but it did cause adrenal enlargement and elevation of plasma corticosteroid levels. Excitation of the rostral or caudal hypothalamus induced further adrenal enlargement without substantial

change in other indices of adrenocortical activity. These and other observations "support the view that the portions of the hypothalamus involved in the regulation of TSH [TTH] and ACTH secretion are overlapping and diffuse rather than discrete."

Brodish, A.: "Role of the hypothalamus in the regulation of ACTH release." In: Bajusz, E. and Jasmin, G., *Major Problems in Neuroendocrinology*, pp. 177-195. Basel and New York: S Karger, 1964. E3,993/64

In rats, electrolytic lesions in the hypothalamus interfere with stress-induced ACTH release more by delaying than by preventing it. The duration of the delay largely depends upon the magnitude of the hypothalamic lesions. "Nevertheless these animals were capable of a delayed response which approached to within 90% of the secretion of hormone observed in normal rats" (32 refs.).

Yoshio, H.: "Inhibitory effect of pre-optic stimulation on adrenal 17-hydroxycorticosteroid secretion rate in the cat." *Nature* **201**: 1334-1335 (1964). G10,717/64

Slusher, M. A.: "Effects of chronic hypothalamic lesions on diurnal and stress corticosteroid levels." *Am. J. Physiol.* **206**: 1161-1164 (1964). F10,922/64

In unanesthetized, unrestrained rats, "anterior hypothalamic lesions bilaterally destroying the periventricular zone and arcuate nuclei were associated with inhibition of the normal 5 PM rise but with normal rise in plasma corticosteroid levels in response to sound or to a 1-min electrical stimulation of the posterior diencephalon. Posterior tuber cinereum lesions were associated with normal 5 PM rise but with inhibition of response to sound. Response to ether stress was unaffected by any lesion."

Brodish, A.: "Delayed secretion of ACTH in rats with hypothalamic lesions." *Endocrinology* **74**: 28-34 (1964). F30,764/64

Experiments in rats with hypothalamic

lesions of various sizes and locations. Especially when large areas were destroyed the rapid stress-induced release of ACTH was prevented, but there remained a substantial delayed response in which the plasma corticosterone concentration "was almost 90% of that found in control rats." This was associated with ascorbic acid depletion.

Szentagothai, J.: "The parvicellular neurosecretory system." *Prog. Brain Res.* **5**: 135-146 (1964). J12,757/64

"A peculiar neuron system is demonstrated in the ventral part of the hypothalamus by the aid of the rapid Golgi technique in the dog and the cat. Its small cell bodies are situated in the arcuate (infundibular), and in the ventral part of the anterior periventricular nuclei, as well as in the medial part of the retrochiasmatic region." The axons of these cells can be traced to the proximal part of the pituitary, the ME, where they terminate in the zona palisadica of Martinez. This system corresponds exactly to the "hypophysiotrophic region" of Halász, which is where the CRF probably originates.

Eik-Nes, K. B., Brizzee, K. R.: "Concentration of tritium in brain tissue of dogs given [1,2-³H₂] cortisol intravenously." *Biochim. Biophys. Acta* **97**: 320-333 (1965). G26,963/65

In dogs given [1,2-³H₂] cortisol, the hypothalamus took up radioactivity with somewhat pronounced selectivity. "It is postulated that cortisol inhibition of the adrenal pituitary axis primarily occurs at a hypothalamic level." Considerable evidence in support of this view is quoted from the literature (27 refs.).

Mitro, A., Mikulaj, L.: "Karyometric changes in the hypothalamus of the male albino rat during adaptation to repeated stress. I. NN. ventromedialis, dorsomedialis and arcuatus." *Biológia* (Bratislava) **20**: 856-861 (1965) (Slovak). J24,460/65

Discussion of the literature on the clinical value of ACTH stimulation, metyrapone, pyrogen, vasopressin, insulin, hypoglycemia, and dexamethasone suppression tests, which help to clarify the neurohumoral mechanisms responsible for corticoid secretion.

Bouillé, C., Baylé, J.-D.: "Experimental studies on the adrenocorticotropic area in the pigeon hypothalamus." *Neuroendocrinology* **11**: 73-91 (1973).

H66,001/73

In pigeons, hypothalamic control of stress-induced adrenocortical activity was examined by means of hypothalamic lesions combined with hypophysectomy or pituitary autografts. "A well-defined adrenocorticotropic area is present in the posterior medial and lateral hypothalamic region. Destruction of the area leads to the same decrease of the plasma

corticosterone level as is seen after adeno-hypophysectomy and also prevents the progressive recovery of adrenocortical function after autografting. The adrenal cortical response to various stressful stimuli is suppressed after lesioning of this same area." It remains to be seen whether the residual adrenocortical responsiveness of hypophysectomized pigeons is due to partial autonomy of the gland or to some extrahypophyseal control system. In any case, corticotrophic activity is abolished by destruction of the regulating hypothalamic area, and hence the hypothesis of the functional autonomy of the pigeon adrenal "is invalidated."

H83,654/74

In rhesus monkeys, electric stimulation of the hypothalamus caused a rise in plasma 17-OHCS, especially during the initial excitement. Although increases were obtained after stimulation of various sites scattered throughout the anterior, tuberal and posterior parts of the lateral hypothalamus, plasma STH rose only when the posterior sites were stimulated. This pattern of a smaller hypothalamic area for STH than for ACTH release has also been observed in the rat, cat and squirrel monkey, and is probably a general principle of organization.

H85,990/74

Excellent and very succinct review on factors regulating corticoid production. The neurohumoral mechanisms are summarized in Figure 13 (p. 978).

Aldosterone secretion occurs in the glomerulosa which, unlike the fasciculata and reticularis, undergoes no atrophy following glucocorticoid overdosage. However, aldosterone discharge by the glomerulosa is stimulated by angiotensin, and this effect is not prevented by corticoid-induced adrenocortical atrophy.

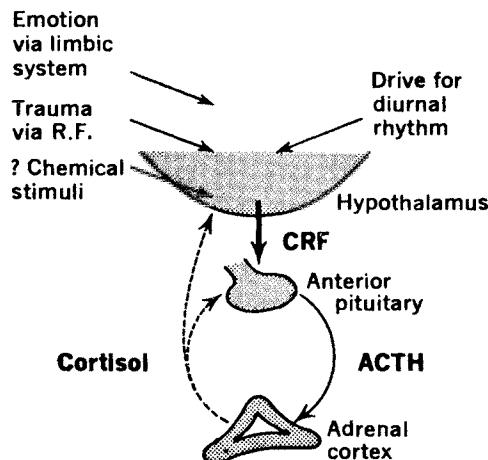

Figure 13. Diagram of current concepts of the control of ACTH secretion. The dashed arrows indicate inhibitory effects and the solid arrows stimulating effects. RF = reticular formation. Hypothalamic Deafferentation

(See also our earlier stress monographs, p. xiii)

Egdahl, R. H.: "Further studies on adrenal cortical function in dogs with isolated pituitaries." *Endocrinology* **71:** 926-935 (1962). D45,363/62

In dogs, removal of the brain down to the pons or preparation of "hypothalamic is-

lands," as well as ablation of the entire brain and spinal cord, initially depressed adrenocortical function and then elevated the resting secretion. Neither removal of the posterior pituitary nor abdominal evisceration altered this response.

Matsuda, K., Kendall, J. W. Jr., Duyck, C., Greer, M. A.: "Neural control of ACTH secretion: effect of acute decerebration in the rat." *Endocrinology* 72: 845-852 (1963).

D67,087/63

Removal of the cerebral cortex and subjacent brain rostral to the superior colliculus did not increase peripheral plasma corticosterone in the rat. Hence, it is doubtful that the pituitary is released from inhibition by this operation in this species, as has been reported for dogs. "The minimal amount of tissue permitting approximately normal pituitary-adrenocortical activation appeared to be the median eminence-stalk-pituitary complex."

Matsuda, K., Duyck, C., Kendall, J. W. Jr., Greer, M. A.: "Pathways by which traumatic stress and ether induce increased ACTH release in the rat." *Endocrinology* 74: 981-985 (1964).

F12,792/64

In rats, removal of all forebrain anterior to the superior colliculus, leaving an isolated ME, stalk and pituitary intact, still permits ACTH release (corticosterone in adrenal effluent in response to ether anesthesia) with or without traumatic stress (fracture of foreleg). However, after Nembutal anesthesia, traumatic stress is not active in this respect. Bone fracture distal to a section of the spinal cord of otherwise intact rats also fails to raise adrenocortical secretion under Nembutal but not under ether anesthesia. "Ether apparently directly stimulates the median eminence to cause increased ACTH release. Traumatic stress induces ACTH release through ascending neural pathways feeding into the hypothalamus through the dorsal mesencephalon."

Halász, B., Pupp, L.: "Hormone secretion of the anterior pituitary gland after physical interruption of all nervous pathways to the hypophysiotrophic area." *Endocrinology* 77: 553-562 (1965).

F49,818/65

Review of earlier studies which showed that in rats the transplanted pituitary maintains its structure and function only if placed in direct contact with the ME. To further elucidate this problem, "a small knife was designed, fixed on the electrode holder of a

stereotaxic instrument, and used to cut around the hypophysiotrophic area leaving the area in contact with the pituitary by means of the unbroken pituitary stalk." Adrenal weight was increased, and lipid distribution in the cortex indicated enhanced ACTH secretion, yet the corticosterone content of adrenal venous blood was not appreciably changed. Following deafferentation, the thyroid weight and structure, hypertrophy after methylthiouracil, and the appearance of the testes were maintained, but the ovaries decreased in size and showed histologic changes. Apparently the hypothalamus is largely autonomous in regulating pituitary activity, but is subject to control by afferent nervous stimuli.

Halász, B., Slusher, M. A., Gorski, R. A.: "Adrenocorticotrophic hormone secretion in rats after partial or total deafferentation of the medial basal hypothalamus." *Neuroendocrinology* 2: 43-55 (1967).

F81,329/67

In rats a few weeks after deafferentation of the medial basal hypothalamus by means of the Halász knife, plasma and adrenal corticosterone levels were greatly increased, except in the venous effluent. Unilateral adrenalectomy under ether further raised the corticosterone levels in these rats, and the remaining adrenal underwent compensatory hypertrophy. The circadian rhythm was abolished by total deafferentation or selective transection of the anterior pathways to the MBH but not by transection of the lateral, dorsal and posterior connections to it. Presumably, the anterior pathways convey afferent input for circadian variations. "It is concluded that ACTH secretion of the anterior pituitary is maintained by the MBH in the absence of neural input. For normal ACTH function, however, afferent impulses to the MBH are required."

Halász, B., Vernikos-Danellis, J., Gorski, R. A.: "Pituitary ACTH content in rats after partial or total interruption of neural afferents to the medial basal hypothalamus." *Endocrinology* 81: 921-924 (1967).

F89,131/67

"Complete deafferentation of the MBH resulted in a marked increase in pituitary ACTH content and a disappearance of the diurnal ACTH rhythm present in the sham-operated controls. Similar findings were obtained after the interruption of the anterior connections of the MBH, leaving all other afferents intact. The severance of the dorsal, lateral and posterior connections of the MBH

did not interfere with pituitary ACTH content, including the diurnal ACTH rhythm. It is concluded that the neural pathways reaching the MBH from anterior are essential for the maintenance of normal ACTH secretion."

Greer, M. A., Rockie, C.: "Inhibition by pentobarbital of ether-induced ACTH secretion in the rat." *Endocrinology* 83: 1247-1252 (1968). H5,714/68

In rats, ether anesthesia stimulated ACTH release, apparently acting through the ME. Pentobarbital anesthesia actually blocked this release, as indicated by plasma corticosterone levels. Rats with hypothalamic-pituitary islands (Halász knife) had high resting plasma corticosterone levels, which further increased after ether. Pentobarbital also blocked this response. Presumably, "pentobarbital acts on the basal hypothalamus to prevent ether from inducing ACTH release but does not prevent ACTH release following trauma."

Feldman, S., Conforti, N., Chowers, I., Davidson, J. M.: "Differential effects of hypothalamic deafferentation on responses to different stresses." *Isr. J. Med. Sci.* 4: 908-910 (1968). H3,150/68

Following deafferentation of the hypothalamus (Halász knife), both the normal concentration of plasma corticosterone of rats and its considerable increase after "ether stress" are unchanged. On the other hand, "audiogenic stress" appears to produce no evidence of ACTH discharge. "It might be possible to subdivide ACTH-releasing stimuli into 'systemic' or 'neurogenic' on the basis of whether or not they can activate the hypothalamo-pituitary unit in the absence of afferent nervous input to this area."

Palka, Y. S., Coyer, D. D., Critchlow, V.: "Hypothalamic deafferentation and adrenal function." *Fed. Proc.* 27: 217 (1968). H56/68

Following complete deafferentation of the hypothalamus, the circadian rhythm of corticosterone secretion was abolished in rats. The same result was obtained by blocking the anterior, but not the posterior, input into the MBH. The response to ether was not prevented even after total deafferentation, whereas the stimulating effect of immobilization and the suppression caused by dexamethasone were abolished.

Voloschin, L., Joseph, S. A., Knigge,

K. M.: "Endocrine function in male rats following complete and partial isolations of the hypothalamo-pituitary unit." *Neuroendocrinology* 3: 387-397 (1968). H5,991/68

In rats with total or partial deafferentation of the hypothalamus by a modified Halász knife, it was found that "a) the isolated hypothalamo-pituitary unit is capable of responding to ether stress, although at a submaximal level, b) differential effects may be obtained from animals with total isolations depending upon the amount of neural tissue included in the knife cut, c) some of the neural afferents which influence the ACTH-releasing principles of median eminence origin ascend from caudal regions of the CNS and in the hypothalamus traverse a path within 1 mm of the midline."

Joseph, S. A., Knigge, K. M., Voloschin, L.: "Effects of isolation of the hypothalamo-pituitary unit in newborn guinea pigs." *Neuroendocrinology* 4: 42-50 (1969).

H8,974/69

In newborn guinea pigs, deafferentation of the hypothalamus with a modified Halász knife showed that within about three months "growth and gonadal function were most seriously impaired; development of thyroid and adrenal function was unaffected in male animals and only moderately affected in females. The results indicate that those RF-producing neurones associated with growth hormone and the gonadotrophins may require afferent neural connections for their normal maturation, while RF-producing neurones associated with thyrotrophin and corticotrophin may develop normally in the isolated hypothalamo-pituitary unit."

Dunn, J., Critchlow, V.: "Feedback suppression of 'non-stress' pituitary-adrenal function in rats with forebrain removed." *Neuroendocrinology* 4: 296-308 (1969).

H14,759/69

In rats, forebrain removal or brain stem transection did not interfere with the suppression of corticoid secretion by dexamethasone, "suggesting that negative feedback acts in part directly on anterior pituitary." Rats with large hypothalamic islands had unusually high plasma corticosterone levels, whereas those with basal hypothalamic islands, pituitary islands, or brain stem transections maintained their blood corticoids within essentially normal limits.

Dunn, J., Critchlow, V.: "Pituitary-adrenal response to stress in rats with hypotha-

lamic islands." *Brain Res.* **16**: 395-403 (1969).
H9,631/69

Plasma corticosterone levels were determined in rats in which the mesencephalo-diencephalic junction was severed and graded amounts of forebrain removed, leaving either a hypothalamic island (HI), a basal hypothalamic island (BHI), or a pituitary island (PI). Sham-operated and intact animals served as controls. "Stress plasma samples were obtained 15 min following onset of 3-min ether or immobilization stress. Whereas BHI, sham-operated and intact rats had comparable 'non-stress' Cpd B [corticosterone] levels and showed significant stress responses, HI rats had higher 'non-stress' Cpd B levels and did not show stress responses. PI rats did not respond to stress but had 'non-stress' Cpd B levels comparable to those of controls. These results suggest that the isolated hypothalamo-pituitary unit responds to stress if 'non-stress' Cpd B levels are not elevated. The inability of PI rats to respond to stress implies that the hypothalamus and/or median eminence are essential to the stress response." Thus, hypothalamic deafferentation and forebrain removal indicate that hypothalamic regulation of ACTH secretion is largely independent of neural connections with other parts of the CNS. "This is not to say, however, that limbic, midbrain, and other neural structures do not influence pituitary-adrenal function in the intact animal." [Clearly, all theories suggesting that every stressor must travel to the hypothalamus-pituitary system by nervous pathways from the site of injury are no longer tenable (H.S.).]

Halász, B.: "Endocrine function of hypothalamic islands." In: Gual, C. and Ebling, F. J. G., *Progress in Endocrinology* (Proc. 3rd Int. Congr. Endocrinol., Mexico) *Int. Congr. Ser.* No. 184, pp. 508-514. Amsterdam and New York: Excerpta Medica, 1969.

J11,124/69

Detailed description of surgical techniques for complete or incomplete deafferentation of the hypothalamus-pituitary complex in the rat. A résumé of the many experiments performed with these techniques showed that there may be 2 levels of neural control of the anterior pituitary: "(1) One level seems to be represented by the medial basal hypothalamus (the hypophysiotrophic area). We assume that this hypothalamic region produces the releasing and inhibiting factors essential for the anterior lobe (releasing fac-

tors system). The area may be responsible by itself for maintaining the basal secretion of pituitary hormones and appears to be able to produce and release the 'hypophysiotrophic' substances in the absence of neural afferents. (2) The nervous structures located outside the medial basal hypothalamus and involved in the neural control of the anterior pituitary can be considered the second control level. This level consists of several structures (various hypothalamic areas outside the hypophysiotrophic area, limbic system, midbrain reticular formation, cortex, etc.). Our data suggest that the ovulatory mechanism is triggered, at least partly, by the preoptic area itself and that the neural afferents essential for the diurnal ACTH rhythm enter the hypophysiotrophic area from the anterior direction. The second control level probably does not act directly on the adenohypophysis, but exerts its influence via the medial basal hypothalamus (release regulating system)."

Halász, B.: "The endocrine effects of isolation of the hypothalamus from the rest of the brain." In: Ganong, W. F. and Martini, L., *Frontiers in Neuroendocrinology*, pp. 307-342. New York, London and Toronto: Oxford University Press, 1969.

J11,367/69

Excellent review of the effects of hypothalamic deafferentation, based mainly on the author's personal work. There appear to be "two levels in the neural control of the anterior pituitary. One level is in the medial basal hypothalamus. It seems likely that this region stores or produces the hypothalamic releasing and inhibiting substances that regulate anterior pituitary secretion. The area appears to be able to produce and release these substances in the absence of neural afferents, and is probably responsible by itself for the maintenance of the basal secretion of the anterior lobe hormones. The feedback action of the peripheral hormones and the action of some other substances appear to be exerted on this region. The other level is in neural structures located outside the medial basal hypothalamus. This level exerts stimulatory as well as inhibitory effects on the adenohypophysis, and probably acts via the medial basal hypothalamus. The ovulatory surge of LH from the anterior lobe is triggered, at least in part, from the preoptic area." In rats, complete deafferentation of the medial ventral hypothalamus does not interfere with the basal secretion of pituitary tropic hormones, and fails to cause atrophy of their

target organs. Compensatory hypertrophy of the adrenals develops after unilateral adrenalectomy; there is ACTH release after stress, and propylthiouracil elicits thyroid hypertrophy. Castration increases the LH content of the anterior lobe and causes formation of castration cells. Growth is only slightly retarded. However, such rats do not ovulate, and the diurnal rhythm of ACTH secretion is abolished.

Makara, G. B., Stark, E., Palkovits, M., Révész, T., Mihály, K.: "Afferent pathways of stressful stimuli: corticotrophin release after partial deafferentation of the medial basal hypothalamus." *J. Endocrinol.* **44**: 187-193 (1969). H15,202/69

Observations on rats after deafferentation of the MBH with the Halász knife led to the conclusion that "(a) noise and vibration, sham adrenalectomy and injection of 1% formalin trigger ACTH release through neural pathways arriving at the MBH from anterior, lateral and dorsal directions, (b) histamine or capsaicin releases ACTH partly through anterolateral neural afferents to the MBH. In contrast, the ACTH-releasing stimulus of bacterial endotoxin injection reaches the hypothalamo-hypophysial unit by humoral pathways and/or posterior nerve fibres."

Palka, Y., Coyer, D., Critchlow, V.: "Effects of isolation of medial basal hypothalamus on pituitary-adrenal and pituitary ovarian functions." *Neuroendocrinology* **5**: 333-349 (1969). H23,543/69

In rats, deafferentation of the medial basal hypothalamus with a modified Halász knife eliminated "the diurnal peak in non-stress plasma corticosterone levels. Such isolation was compatible with a normal response to 3-min ether stress; the response to immobilization stress was present, though significantly reduced." Dexamethasone given subcutaneously suppressed resting plasma corticosterone levels. On the other hand, isolated interruption of the anterior connections of this hypothalamic area did not measurably influence ACTH secretion under these conditions.

Feldman, S., Conforti, N., Chowers, I., Davidson, J. M.: "Pituitary-adrenal activation in rats with medial basal hypothalamic islands." *Acta Endocrinol. (Kbh.)* **63**: 405-414 (1970). H23,303/70

In rats with deafferentation of the hypothalamus (Halász knife), the increase in plasma corticosterone produced by ether remained unaffected, and that elicited by ether

plus venesection was only slightly inhibited. Conversely, the hypercorticism following auditory or optic stimulation was considerably diminished, and that following hypoxia and immobilization was totally unaffected. "It is concluded that (1) ACTH release following auditory, and to a somewhat lesser extent, optic stimulation depends on neural input to the basal medial hypothalamus and (2) the corticotrophic responses to ether, anoxia and immobilization may be mediated by humoral activation of the same region."

Makara, G. B., Stark, E., Palkovits, M.: "Afferent pathways of stressful stimuli: corticotrophin release after hypothalamic deafferentation." *J. Endocrinol.* **47**: 411-416 (1970). H29,802/70

In rats with complete deafferentation of the medial basal hypothalamus, capsaicin failed to increase plasma corticosterone levels, but *E. coli* endotoxin, histamine, insulin and formaldehyde continued to produce normal ACTH release. Histamine and insulin were effective in this respect, even in rats having only an ME-pituitary stalk island. Presumably, among the agents tested only capsaicin is totally dependent upon neural pathways for causing ACTH release.

Greer, M. A., Allen, C. F., Gibbs, F. P., Gullickson, C.: "Pathways at the hypothalamic level through which traumatic stress activates ACTH secretion." *Endocrinology* **86**: 1404-1409 (1970). H26,878/70

In rats, complete hypothalamic deafferentation (Halász knife) blocked the rise in plasma corticosterone normally caused by fracture of a leg on either side. Unilateral deafferentation significantly abolished this increase after contralateral, but not ipsilateral, leg break. The effect of contralateral leg fracture was also blocked by a one-sided anterior quarter section, but not by a posterior quarter section. Not even complete hypothalamic deafferentation suppressed the rise in plasma corticosterone following placement of a rubber band tourniquet on a single extremity. "The pathway via which a single leg break causes increased ACTH secretion is usually contralaterally distributed at the level of the basal hypothalamus as well as through the spinal cord to the pons. This pathway enters the anterior basal hypothalamus within 1 mm of the ventral brain surface. A rubber band tourniquet probably increases ACTH secretion through some pathway different from that followed by the stimulus of a leg break."

Stark, E., Makara, G. B., Palkovits, M., Mihály, K.: "Afferent pathways of stressful stimuli: their dependence on strength and the time elapsed after the onset of stimulation." *Acta Physiol. Acad. Sci. Hung.* **38**: 43-49 (1970). G81,960/70

Observations on rats with anterolateral deafferentation of the MBH and denervation of a hind limb show that the resulting plasma corticosterone elevations are variable. "A change in the intensity of a stressful stimulus can involve another pathway; with time, different pathways may be at work after exposure to some stressful stimuli but not to others."

Chowers, I., Conforti, N., Feldman, S.: "Effects of hypothalamic deafferentation on adrenocortical responses to cold stress." *Isr. J. Med. Sci.* **7**: 323-325 (1971).

H62,648/71

In rats, hypothalamic deafferentation (Halász knife) only partially inhibits corticoid production during cold-induced stress.

Halász, B., Schalch, D. S., Gorski, R. A.: "Growth hormone secretion in young rats after partial or total interruption of neural afferents to the medial basal hypothalamus." *Endocrinology* **89**: 198-203 (1971).

H43,027/71

In rats, hypothalamic deafferentation does not significantly affect STH secretion, even during stress.

Makara, G. B., Stark, E., Mészáros, T.: "Corticotrophin release induced by *E. coli* endotoxin after removal of the medial hypothalamus." *Endocrinology* **88**: 412-414 (1971).

H35,419/71

In rats, one day after division of the pituitary stalk or removal of the medial hypothalamus, intraperitoneal *E. coli* endotoxin produced a small but significant rise in plasma corticosterone. Presumably, "some of the pathways through which *E. coli* endotoxin releases corticotrophin bypass the medial hypothalamus."

Halász, B.: "Neural control of pituitary ACTH secretion under resting conditions." *Acta Med. Acad. Sci. Hung.* **29**: 71-76 (1972).

J10,354/72

Brief review on the neural control of ACTH secretion under resting conditions. The MBH elaborates CRF, but receives stimuli from external areas such as the limbic system, mesencephalon, and so on. Some of these regions presumably stimulate, while others inhibit, ACTH production (35 refs.).

Feldman, S., Conforti, N., Chowers, I.: "Effects of partial hypothalamic deafferentations on adrenocortical responses." *Acta Endocrinol. (Kbh.)* **69**: 526-530 (1972).

H52,370/72

In rats with anterior hypothalamic deafferentation, only ACTH secretion remained unchanged under the stress of ether, light and noise, while in those with anterolateral and posterolateral deafferentation the response to ether was normal, but the response to photic and acoustic stimulation was significantly inhibited. Presumably, "the transmission of impulses in the medial forebrain bundle and possibly posterior sensory inputs to the hypothalamus play an important role in the adrenocortical responses following neurogenic stimulation."

Ondo, J. G., Kitay, J. I.: "Effects of dexamethasone and stressful stimuli on hypothalamic electrical activity in rats with diencephalic islands." *Neuroendocrinology* **9**: 215-227 (1972).

H56,043/72

In rats with diencephalic islands (Cross and Kitay technique), dexamethasone was shown to have a direct effect on the neurons of the isolated basal hypothalamus. However, vasopressin and histamine, which have an inverse influence on ACTH secretion, similarly inhibited the firing of hypothalamic neurons. Thus, "a simple explanation relating neuronal firing rate and the mechanisms involved in the control of ACTH secretion is obviously not possible." The literature on the effect of various hormones on hypothalamic neurons is reviewed.

Bouillé, C., Herbuté, S., Baylé, J.-D.: "Modulatory influences of central nervous structures on pituitary-adrenocortical activity: effect of chronic deafferentation of the hypothalamus in the pigeon." *J. Physiol. (Paris)* **66**: 437-446 (1973).

J9,213/73

In Carneau pigeons, deafferentation of the hypothalamus with a modification of the Halász knife suppressed the usual circadian variations in plasma corticosterone levels. Responses to ether stress were reduced but not abolished.

Vermes, I., Molnár, D., Telegdy, G.: "Hypothalamic serotonin content and pituitary-adrenal function following hypothalamic deafferentation." *Acta Physiol. Acad. Sci. Hung.* **43**: 239-245 (1973).

J12,931/73

In rats, partial or total deafferentation of the hypothalamus decreases the adrenal response to "ether stress" and concurrently di-

minishes hypothalamic 5-HT concentration. The findings support the concept that "serotonin plays an inhibitory role in the function of the hypothalamo-pituitary-adrenal axis, and indicate that serotonergic fibres are reaching the hypothalamus from the anterior and antero-superior parts."

McCann, S. M., Ajika, K., Fawcett, C. P., Hefco, E., Illner, P., Negro-Vilar, A., Orias, R., Watson, J. T., Krulich, L.: "Hypothalamic control of the adenohypophyseal response to stress by releasing and inhibiting neurohormones." In: Németh, Š., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 67-77. Bratislava: Slovak Academy of Sciences, 1973. E10,458/73

Mainly on the basis of plasma hormone determinations and observations in rats whose hypothalamus-pituitary system was isolated with the Halász knife, the authors were led to the conclusion that "following the application of a stressful stimulus, afferent impulses are probably generated which pass to the brainstem and thence to the hypothalamus where they influence release of the various releasing and inhibiting hormones which control the AP [anterior pituitary]. We would postulate that the afferent pathways are similar for all AP hormones and that the differential patterns of release are brought about by specific intrahypothalamic mechanisms. Consistent with this hypothesis is the differential localization of the various releasing and inhibiting factors in the hypothalamus." Even transfer from the stock room to the laboratory sufficed to cause a dramatic increase in the rats' serum STH and LH values within less than one hour.

Collu, R., Jéquier, J. C., Letarte, J., Leboeuf, F., Ducharme, J. R.: "Effect of stress and hypothalamic deafferentation on the secretion of growth hormone in the rat." *Neuroendocrinology* 11: 183-190 (1973). H68,127/73

Ether and auditory stressors were equally effective in diminishing plasma STH (radioimmunoassay) in controls and in frontally deafferented rats. Ether also inhibited STH secretion in completely deafferented animals, whereas auditory stress was ineffective. α -MT pretreatment blocked the effect of ether after complete deafferentation. These and other data "seem to indicate that ether stress is transmitted through a humoral, dopaminergic pathway, while auditory stress follows a nervous pathway." [The many ob-

servations suggesting increased STH secretion during stress are not discussed (H.S.).]

Feldman, S., Conforti, N., Chowers, I.: "Effect of dexamethasone on adrenocortical responses in intact and hypothalamically deafferented rats" (abstracted). *Isr. J. Med. Sci.* 10: 572 (1974). H89,689/74

Inhibition of ACTH secretion by dexamethasone is more pronounced in intact than in hypothalamically deafferented rats. Apparently, the negative feedback of corticoids is exerted at the hypothalamic level, but extrahypothalamic structures also participate in it.

Vermesh, I., Ryzhenkov, V. E.: "Functional condition of the hypophysis-adrenal system in rats with deafferentated hypothalamus; the action of dexamethasone and nialamide." *Probl. Endokrinol. (Mosk.)* 20 No. 3: 67-70 (1974) (Russian). H92,315/74

In rats with a completely deafferented MBH, the basal plasma corticosterone level rose; this elevation could be inhibited by dexamethasone or nialamide. "At the same time suppression of corticosterone secretion in stress [restraint] by nialamide was stronger in comparison with dexamethasone. Nialamide potentiated the depressive action of dexamethasone on the basal corticosterone secretion, but not under stress."

Allen, C. F., Allen, J. P., Greer, M. A.: "Anterolateral hypothalamic deafferentation prevents compensatory hypersecretion of ACTH following adrenalectomy in the rat." *Proc. Soc. Exp. Biol. Med.* 146: 840-843 (1974). H89,021/74

"Complete or anterolateral, but not anterior, basal hypothalamic deafferentation prevented the increased basal secretion of ACTH in chronically adrenalectomized rats. ACTH secretion in response to ether stress was at least as great in the deafferented, adrenalectomized rats as in intact controls." Presumably, extrahypothalamic influences entering the basal hypothalamus are necessary to achieve high basal ACTH secretion when plasma glucocorticoids are depressed.

Conforti, N., Feldman, S., Chowers, I.: "Adrenal function in heat-exposed hypothalamically-disconnected rats." *Isr. J. Med. Sci.* 10: 291 (1974). H86,881/74

In rats with hypothalamic deafferentation (Halász knife), corticosterone release following exposure to heat was diminished, but was nevertheless demonstrable following repeated exposure. These and other observations led

to the conclusion that CRF discharge following exposure to heat depends upon direct connections between peripheral heat receptors mediated by afferent pathways and systemic influences.

Krulich, L., Hefco, E., Aschenbrenner, J. E.: "Mechanism of the effects of hypothalamic deafferentation on prolactin secretion in the rat." *Endocrinology* **96**: 107-118 (1975).

H98,036/75

Insula of Reil

(See also our earlier stress monographs, p. xiii)

Misra, D. K.: "Insula and adrenocortical function." *Calcutta Med. J.* **69**: 96-107 (1972). H79,786/72

In dogs, unilateral or bilateral stimulation of the insula of Reil raised the 17-OHCS content of adrenal venous blood. No significant change was noted after lesions of the same region, but burn stress enhanced the response. Presumably, the insula, through nervous connections with the hypothalamus across subcortical areas, can activate the hypothalamo-pituitary-adrenal axis.

Limbic System

(See also our earlier stress monographs, p. xiii, and cf. various specifically-named parts of the limbic system)

Mason, J. W.: "Visceral functions of the nervous system." *Annu. Rev. Physiol.* **21**: 353-380 (1959). J11,142/59

Review on the role of the CNS in visceral functions, particularly endocrine regulation. A special section deals with the effect of emotional factors upon the limbic system, the hypothalamus and the reticular formation (219 refs.).

Okinaka, S., Ibayashi, H., Motohashi, K., Fujita, T., Ohsawa, N., Murakawa, S.: "Regulation of the pituitary-adrenocortical function through the limbic system." *Neurol. Med. Chir. (Tokyo)* **2**: 110-115 (1960).

D82,582/60

In dogs, adrenal venous 17-OHCS and blood ACTH were determined after electric stimulation of the posterior orbital surface, amygdaloid nuclear complex, hippocampus

and midbrain reticular formation. It was concluded that "the stimulation of the posterior orbital surface, the amygdaloid nuclear complex, and possibly the midbrain reticular formation especially its caudal portion facilitated the pituitary adrenocortical function transiently, while the stimulation of the hippocampal formation appeared to give a prolonged suppression."

Nauta, W. J. H.: "Limbic system and hypothalamus: anatomical aspects." *Physiol. Rev.* **40** Supp. 4: 102-104 (1960).

J11,497/60

The "limbic forebrain structures" are described as consisting "in part of a relatively primordial cortex (hippocampus, piriform lobe, gyrus forniciatus, caudal orbitofrontal cortex), partly also of subcortical structures (septal region, amygdaloid complex). Together, these structures are arranged in an almost complete ring around the hilus of the cerebral hemisphere, Broca's grand lobe limbique."

Okinaka, S., Ibayashi, H., Motohashi, K., Fujita, T., Yoshida, S., Ohsawa, N.: "Effect of electrical stimulation of the limbic system on pituitary-adrenocortical function: posterior orbital surface." *Endocrinology* **67**: 319-324 (1960).

J12,153/60

"The role of limbic system structures in the regulation of ACTH secretion."

Mason, J. W., Nauta, W. J. H., Brady, J. V., Robinson, J. A., Sachar, E. J.: "The role of limbic system structures in the regulation of ACTH secretion." *Acta Neuroveg. (Wien)* **23**: 4-14 (1961). E94,848/61

In conscious monkeys, electric stimulation of the amygdala causes pronounced rises in plasma 17-OHCS that are followed by a depression if the stimulus continues for several hours. Stimulation of the distal tip of the hippocampus causes a slight acute elevation, followed by a pronounced and prolonged depression, of 17-OHCS levels. Bilateral amygdalectomy diminishes the acute rise in 17-OHCS normally elicited by conditioned avoidance sessions. "These experiments indicate an important modulatory role for limbic structures in the regulation of endocrine functions."

Okinaka, S.: "Die Regulation der Hypophysen-Nebennierenfunktion durch das Limbic-System und den Mittelhirnanteil der Formatio reticularis" (The role of the limbic system and the midbrain portion of the re-

ticular formation in regulating hypophyseal-adrenal function). *Acta Neurolog. (Wien)* **23**: 15-20 (1962). J11,476/62

In dogs, "stimulation of the posterior orbital surface, the prepyriformic region, transitory area between pyriformic lobe and olfactory tract, resulted in a prompt and pronounced elevation of both 17-OHCS and ACTH content, which returned to the pre-stimulation level 30 minutes later. No such increase was demonstrated upon stimulation of the anterior sylvian gyrus. Stimulation of amygdaloid nuclear complex resulted in a similar elevation of 17-OHCS and ACTH content. Stimulation of hippocampal formation, however, resulted in a decrease of 17-OHCS and ACTH for 30 minutes. The role of posterior orbital surface and the amygdaloid nuclear complex thus appears to be facilitating, while that of hippocampal formation seems to be inhibitory, on the pituitary-adrenal system."

Rubin, R. T., Mandell, A. J., Crandall, P. H.: "Corticosteroid responses to limbic stimulation in man: localization of stimulus sites." *Science* **153**: 767-768 (1966).

F68,624/66

"Corticosteroids in human plasma and urine increase after amygdala stimulation, and plasma corticosteroids decrease after hippocampus stimulation. Five subjects underwent unilateral temporal lobectomy, and histopathologic localization of electrode sites was attempted. Localization was successful for six sites: three in basolateral amygdala and three in hippocampus."

Eleftheriou, B. E., Zolovick, A. J., Pearse, R.: "Effect of amygdaloid lesions on pituitary-adrenal axis in the deer mouse." *Proc. Soc. Exp. Biol. Med.* **122**: 1259-1262 (1966).

F72,633/66

In the deer mouse, lesions in the medial amygdaloid complex increased plasma ACTH and corticosterone levels within twelve hours, presumably by eliminating an inhibitory effect.

Usher, D. R., Kasper, P., Birmingham, M. K.: "Comparison of pituitary-adrenal function in rats lesioned in different areas of the limbic system and hypothalamus." *Neuroendocrinology* **2**: 157-174 (1967).

F88,389/67

Rats exposed to intermittent air blasts develop thymus involution and a pronounced increase in plasma corticosterone and pituitary ACTH levels. Lesions in various loca-

tions of the limbic system and hypothalamus can block these effects independently of each other, indicating that different mechanisms are involved in their production.

McEwen, B. S., Weiss, J. M., Schwartz, L. S.: "Uptake of corticosterone by rat brain and its concentration by certain limbic structures." *Brain Res.* **16**: 227-241 (1969) (35 refs.). J11,765/69

Redgate, E. S.: "ACTH release evoked by electrical stimulation of brain stem and limbic system sites in the cat: the absence of ACTH release upon infundibular area stimulation." *Endocrinology* **86**: 806-823 (1970).

H23,415/70

In cats, "plasma ACTH levels rose promptly after stimulation at sites in the amygdaloid septal complex matching the rapidity of the response to hemorrhage or sciatic nerve stimulation. In contrast, after stimulation at sites in the medullary reticular formation, medial midbrain structures, lemniscal systems, or posterior lateral hypothalamus, the rise in plasma ACTH concentration was consistently delayed for 5-10 min, providing the basis for the suggestion that there are at least 2 different neural systems within the brain of the cat participating in ACTH release." These and related observations indicate "that central nervous system mediated ACTH release is accomplished not by a single system with unified action but by separate subsystems endowed with sufficient independence to produce prompt responses and delayed responses" (71 refs.).

Schadé, J. P.: "The limbic system and the pituitary-adrenal axis." *Prog. Brain Res.* **32**: 2-11 (1970).

Bouillé, C., Baylé, J.-D.: "Effects of limbic stimulations or lesions on basal and stress-induced hypothalamic-pituitary-adrenocortical activity in the pigeon." *Neuroendocrinology* 13: 264-277 (1974).

H81,878/74

It is generally believed that the amygdala facilitates, whereas the hippocampus depresses, ACTH-releasing activity by the hypothalamus. The archistriatum is claimed to constitute the avian homologue of the amygdaloid complex of mammals. Hence, experiments were performed in the conscious pigeon by electric stimulation (implanted electrodes) and bilateral electrolytic lesions. Hippocampal stimulation or lesions induced either a marked drop or rise in plasma corticosterone, whereas archistriate stimulation increased it. Diurnal variations in corticoid levels were suppressed after hippocampal lesions, but stress-induced (restraint) responses were only slightly reduced. In the pigeon the hippocampus appears to inhibit the modulatory system of ACTH activity, whereas the archistriatum (like the amygdala of mammals) antagonizes this effect.

Simonov, P. V.: "Functions of limbic structures according to the information theory of emotions." *Proc. Satellite Symp. Emotions and Visceral Functions*, pp. 43-46. Baku, USSR, 1974 (Russian, with extensive English summary). J17,534/74

Delapaz, R. L., Dickman, S. R., Grosser, B. I.: "Effects of stress on rat brain adenosine 3',5'-monophosphate in vivo." *Brain Res.* 85: 171-175 (1975).

J20,677/75

Observations showing "a relationship between stress and increases in the level of cAMP in several regions of the rat brain. A marked rise is seen in the septum after stress from electric shock or restraint. Smaller increases are seen in hippocampus and brain stem in animals stressed by electric shock. These changes in septum and hippocampus are of interest since these regions are components of the limbic system and, therefore, might be involved in the mediation of emotional responses during stress."

Median Eminence (ME), Tuber Cinereum

(See also our earlier stress monographs, p. xiii, and cf. Ependyma.)

Hume, D. M.: "The neuro-endocrine response to injury: present status of the problem." *Ann. Surg.* 138: 548-557 (1953).

B89,126/53

Review of the literature and personal observations show that stimulation of the ME in the dog causes a release of ACTH with eosinopenia. Following trauma, the ACTH discharge appears to be mediated through this center, although nerve impulses from the injured area are essential for initiating the response (36 refs.).

Halász, B., Szöllössy, L.: "Einfluss peripherischer Denervation auf den hypothalamischen Kernvergrößerungseffekt der Zona Fasciculata der Nebennierenrinde" (The influence of peripheral denervation on the hypothalamic enlargement effect of nuclei in the fasciculata of the adrenal). *Acta Morphol. Acad. Sci. Hung.* 3: 1-9 (1953).

B88,339/53

In rats, lesions in the tuber cinereum cause enlargement of the nuclei in the fasciculata of the adrenal. This effect is blocked by transection of the preganglionic and sensory nerves of the adrenal; in fact, after such

denervation, tuber lesions diminish nuclear volume in the same region of the adrenal.

McCann, S. M.: "Effect of hypothalamic lesions on the adrenal cortical response to stress in the rat." *Am. J. Physiol.* **175**: 13-20 (1953). B87,327/53

McCann, S. M., Laqueur, G. L., Schreiner, L. H., Rosemberg, E., Anderson, E., Rioch, D. M.: "Effect of hypothalamic lesions on stress induced eosinopenia in the cat." *Fed. Proc.* **12**: 95 (1953). B78,603/53

In cats with lesions in the hypothalamus or pituitary stalk, EP and laparotomy failed to produce the usual eosinopenic reaction.

Ganong, W. F., Hume, D. M.: "Absence of stress-induced and 'compensatory' adrenal hypertrophy in dogs with hypothalamic lesions." *Endocrinology* **55**: 474-483 (1954).

B98,714/54

In dogs, hypothalamic lesions prevent adrenal enlargement following exposure to stressors (trauma) or unilateradrenalectomy, but only if they destroy the ME.

Török, B.: "Lebendbeobachtung des Hypophysenkreislaufes an Hunden" (In vivo observations on hypophyseal circulation in dogs). *Acta Morphol. Acad. Sci. Hung.* **4**: 83-89 (1954). C2,052/54

In dogs and cats, hypophyseal circulation was observed in vivo by use of vital dyes. "Under physiologic conditions—despite rich anastomoses—blood flow is strictly unilateral in the symmetrical halves of the Pars tuberalis → Eminentia medialis → hypophyseal stalk → anterior lobe vascular systems."

Ganong, W. F., Hume, D. M.: "Effect of hypothalamic lesions on steroid-induced atrophy of adrenal cortex in the dog." *Proc. Soc. Exp. Biol. Med.* **88**: 528-533 (1955).

C4,554/55

In unilaterally adrenalectomized dogs in which the ME is destroyed, the remaining adrenal does not undergo atrophy unless the animals are treated with large doses of cortisol. Hypothalamic lesions outside the ME do not have this effect. Apparently, "an intact median eminence is necessary for the increase in ACTH secretion in response to stress, but not for the decrease that follows steroid injection."

Laqueur, G. L., McCann, S. M., Schreiner, L. H., Rosemberg, E., Rioch, D. M., Anderson, E.: "Alterations of adrenal cortical and

ovarian activity following hypothalamic lesions." *Endocrinology* **57**: 44-54 (1955).

C6,334/55

In cats exposed to stressors (EP, laparotomy), suprachiasmatic or posterior hypothalamic lesions failed to interfere with the normal eosinopenia and the secretion of corticoids. Cats with lesions in the ME and adjacent hypothalamus showed very little response to stressful stimuli, and the eosinopenia after laparotomy was slight. Yet reactivity was not completely abolished, and the animals developed diabetes insipidus.

Fulford, B. D., McCann, S. M.: "Suppression of adrenal compensatory hypertrophy by hypothalamic lesions." *Proc. Soc. Exp. Biol. Med.* **90**: 78-80 (1955). C9,816/55

In unilaterally adrenalectomized rats, destruction of the supraopticohypophyseal tract in the rostral portion of the ME prevented compensatory hypertrophy of the remaining suprarenal and produced diabetes insipidus.

Greer, M. A., Erwin, H. L.: "Evidence of separate hypothalamic centers controlling corticotropin and thyrotropin secretion by the pituitary." *Endocrinology* **58**: 665-670 (1956).

C14,624/56

In rats, destruction of the ME "sometimes" inhibited amphenone-induced adrenal hypertrophy, whereas posterior hypothalamic lesions did not significantly affect ACTH secretion but did suppress TTH production. Presumably, the centers for ACTH and TTH secretion are distinct, and the format is limited to the ME.

George, R., Way, E. L.: "The hypothalamus as an intermediary for pituitary-adrenal activation by aspirin." *J. Pharmacol. Exp. Ther.* **119**: 310-316 (1957).

C34,580/57

In rats, lesions of the ME completely blocked adrenal ascorbic acid depletion following treatment with large doses of acetylsalicylic acid.

Knigge, K. M.: "Inhibitor component in the neural control of ACTH release." *Anat. Rec.* **130**: 326 (1958).

J13,015/58

Brief abstract reporting experiments which show that stress (kind of stressor not indicated) causes a biphasic pattern of ACTH secretion in the rat. During the first one to two hours, there occurs an elevated discharge of ACTH, which is followed by a fall to about one-fifth the normal level at twelve

to eighteen hours after stress. The drop in hormone secretion is not due to secretory exhaustion of the adrenals, since the latter still respond normally when incubated with ACTH in vitro, and the ACTH content of the pituitary is up to twice normal at twelve hours after stress. Presumably, "there exists an inability of the pituitary to release ACTH because of the activity of a neural inhibitor mechanism." Lesions placed in the ME area, or treatment with reserpine two hours after stress, interfere with this pituitary inhibition and result in "adrenal secretion 12 hours after stress which is greater than that observed at any time in the untreated, stressed animal."

Royce, P. C., Sayers, G.: "Extrapituitary interaction between Pitressin and ACTH." *Proc. Soc. Expt. Biol. Med.* **98**: 70-74 (1958).

C54,346/58

Natural vasopressin depletes adrenal ascorbic acid in hypophysectomized rats and potentiates the corresponding action of ACTH, even after destruction of the ME. "Only part of this effect can be explained by release of ACTH from the pituitary since Pitressin will also deplete adrenal ascorbic acid in a lesioned rat which has been decapitated."

Fortier, C., Groot, J. de: "Release and synthesis of ACTH following electrolytic destruction of the median eminence in the rat." *21st Int. Congr. Physiol. Sci.*, p. 96. Buenos Aires, 1959.

J12,865/59

Metuzals, J.: "The structure of the hypothalamic final common path to the adenohypophysis in the cat. The periventricular area of the nucleus arcuatus and the eminentia mediana." *J. Comp. Neurol.* **113**: 103-137 (1959).

C82,320/59

Detailed histologic investigation of the paraventricular area of the nucleus arcuatus and the ME in the cat. The final common pathway to the adenohypophysis is complex, yet it appears to be constructed "(a) of neurons, which extend into the adenohypophysis and terminate probably among the gland cells, and (b) of neurons, which terminate in the external layer of the eminentia and establish contact with the gland cells of the adenohypophysis through the hypophysial portal vessels."

Smelik, P. G., Bouman, P. R., Wied, D. de: "The effect of hypothalamic lesions on compensatory adrenal hypertrophy in

rats." *Acta Endocrinol. (Kbh.)* **31**: 451-456 (1959).

C71,164/59

In unilaterally adrenalectomized rats, coagulation of the posterior part of the ME inhibited compensatory hypertrophy, whether the stalk was intact or not. Stalk lesions alone exerted such an effect only during the first four days. Comparable lesions in the anterior and posterior hypothalamus were ineffective in this respect.

Ganong, W. F.: "Adrenal-hypophyseal interrelations." In: Gorbman, A., *Comparative Endocrinology*, pp. 187-201. New York: John Wiley & Sons, 1959.

D2,002/59

A review of the literature and personal observations suggest that there is a "basal" ACTH secretion independent of the ME and probably of the entire hypothalamus, since no one has been able to produce adrenal atrophy by hypothalamic lesions in any location. Only ACTH secretion in response to stressors is mediated through the hypothalamus by a pathway unaffected by corticoids. A second factor "modulating the amount of pituitary secretion" is the blood corticoid level, which acts merely "as a damping, or braking, mechanism on the coarse fluctuations initiated by the neuroendocrine mechanism."

Moll, J., Vogel, T.: "Observations on the effect of lesions in the pituitary stalk and median eminence on the zonation of the adrenal cortex." *Acta Endocrinol. (Kbh.)* **31**: 568-572 (1959).

C71,929/59

In rats, lesions of the pituitary stalk and ME not only block compensatory adrenal hypertrophy but characteristically alter the zonation of the remaining adrenal.

D'Angelo, S. A.: "Thyroid hormone administration and ovarian and adrenal activity in rats bearing hypothalamic lesions." *Endocrinology* **64**: 685-702 (1959).

C68,037/59

In rats with bilaterally, symmetrical electrolytic lesions in the arcuate nucleus and ME, there was ovarian atrophy, reduced thyroid function and hypothalamic obesity, but such lesions had no consistent effect on adrenal morphology. Administration of T_4 and T_3 failed to reverse the gonadal atrophy, but nevertheless it caused adrenal hypertrophy, as it did in intact controls. Such a differential response was also found in rats made severely hypothyroidic by propylthiouracil prior to hypothalamic destruction. Adrenal cortical acti-

vation was also seen in rats with hypothalamic diabetes insipidus and in chronically starved rats with marked hypothalamic deficit. It is presumable that "ACTH secretion can be enhanced by chronic stress despite arcuate-median eminence lesions and that some aspects of thyroovarian interaction may be mediated through a hypothalamic-hypophyseal component."

McCann, S. M., Haberland, P.: "Further studies on the regulation of pituitary ACTH in rats with hypothalamic lesions." *Endocrinology* **66**: 217-221 (1960). J12,283/60

In rats, recent and old lesions in the ME block the ascorbic acid depletion of the adrenals that normally occurs after unilateral adrenalectomy. Such lesions induce adrenal atrophy in the presence of normal-sized testes. The adrenal ascorbic acid depletion in rats with atrophic adrenals is variable, and only some of these animals have diabetes insipidus. The pituitary ACTH falls only some time after the ME lesions.

Krieger, D. T., Wagman, I. H.: "Hypothalamic lesions and adrenal function in the cat." *Acta Endocrinol. (Kbh.)* **38**: 88-98 (1961). D10,468/61

Cats with bilateral electrolytic lesions of the ME had a low basal blood corticoid level and failed to respond to exogenous or stress-induced ACTH stimulation. Yet the adrenals were enlarged and rich in lipids. "The surprising finding was that these animals with M. E. lesions also did not respond to exogenously administered ACTH." It is assumed that "a lesion of the median eminence depresses adrenal cortical function by interference with release of steroid from the adrenal and not by inducing adrenal atrophy."

Ganong, W. F., Nolan, A. M., Dowdy, A., Luetscher, J. A.: "The effect of hypothalamic lesions on adrenal secretion of cortisol, corticosterone, 11-desoxycortisol and aldosterone." *Endocrinology* **68**: 169-170 (1961). C98,309/61

The output of cortisol, corticosterone, 11-desoxycortisol and aldosterone in the adrenal venous blood of dogs was depressed following destruction of the ME but was unaffected by lesions elsewhere in the hypothalamus.

Wied, D. de: "Effect of hypothalamic lesions and hypophysectomy on corticoid production in vitro and on adrenal weight in rats." *Acta Endocrinol. (Kbh.)* **37**: 279-287 (1961). D5,783/61

In rats with lesions in the ME, stress (ether) inhibited adrenal corticoidogenesis, as tested subsequently in vitro. Vasopressin stimulated corticoidogenesis of the adrenals in such rats. The weight of the adrenals decreased more rapidly after hypophysectomy than after ME lesions. The adrenal hypertrophy usually observed some time after placement of ME lesions did not occur in the present series. Following unilateral adrenalectomy, compensatory hypertrophy of the contralateral adrenal was prevented both by hypophysectomy and by ME lesions.

Miller, R. A.: "Hypertrophic adrenals and their response to stress after lesions in the median eminence of totally hypophysectomized pigeons." *Acta Endocrinol. (Kbh.)* **37**: 565-576 (1961). D80,692/61

In pigeons, hypophysectomy causes adrenal atrophy, but the interrenal tissue hypertrophies during stress elicited by formaldehyde or insulin, even in the absence of the pituitary. Very large lesions in the ME and ventral hypothalamus cause adrenal hypertrophy rather than atrophy, even after total hypophysectomy. They also react to formaldehyde. "It appears that the interrenal tissue of the pigeon responds to a humoral stimulus not of hypophyseal origin in the absence of the hypophyseal-hypothalamic system."

Barry, J., Cotte, G.: "Etude préliminaire, au microscope électronique, de l'éminence médiane du cobaye" (Preliminary electron-microscopic study of the median eminence in the guinea pig.) *Z. Zellforsch. Mikrosk. Anat.* **53**: 714-724 (1961) (about 60 refs.). J12,738/61

Saba, G. C., Saba, P., Marescotti, V.: "Diencephalic lesions and corticosterone production." *Int. Congr. on Hormonal Steroids*, Milan, *Int. Congr. Ser. No. 51*, p. 160. Amsterdam and New York: Excerpta Medica, 1962. J13,136/62

In rats the corticosterone level in the adrenal venous blood diminishes after lesions in the ME but does not after damage to other formations in the hypothalamus.

Kennedy, G. C., Lipscomb, H. S., Hague, P.: "Plasma corticosterone in rats with experimental diabetes insipidus." *J. Endocrinol.* **27**: 345-353 (1963). E35,990/63

In rats, electrolytic lesions in the ME produced diabetes insipidus and variable changes in plasma corticosterone under resting conditions and ether anesthesia.

However, the changes in corticoid levels were not clearly correlated with the severity of the polyuria.

Davidson, J. M., Feldman, S.: "Cerebral involvement in the inhibition of ACTH secretion by hydrocortisone." *Endocrinology* **72**: 936-946 (1963). D67,102/63

In rats, single cortisol implants in the ME and the anteromedial hypothalamus abolished the compensatory adrenal hypertrophy normally produced by unilateral adrenalectomy. Similar implants in the lateral basal hypothalamus elicited only partial inhibition, and implants in the pituitary itself were virtually ineffective. "The hypothalamus rather than the pituitary should be regarded as the primary locus of feedback inhibition of ACTH by hydrocortisone."

Kobayashi, T., Kobayashi, T., Yamamoto, K., Inatomi, M.: "Electron microscopic observation on the hypothalamo-hypophyseal system in the rat. I. The ultrafine structure of the contact region between the external layer of the infundibulum and Pars tuberalis of the anterior pituitary." *Endocrinol. Jap.* **10**: 69-80 (1963). D66,269/63

Halász, B., Pupp, L., Uhlarik, S.: "Changes in the pituitary-target gland system following electrolytic lesions of the median eminence and hypophyseal stalk in male rats." *Acta Morphol. Acad. Sci. Hung.* **12**: 23-31 (1963). D7,234/63

In the rat, "after lesions in the anterior part of the median eminence, thyroid atrophy develops which is considered to be of neurogenic nature.—After lesions in the posterior median eminence or the hypophyseal stalk the pituitary is always reduced in weight and depending on the degree of the lesion a gonadal, or gonadal and thyroid, or in the most severe cases, gonadal, thyroid, and adrenal atrophy develops. Three weeks after a posterior median eminence or stalk lesion no isolated thyroid or adrenal atrophy has been observed.—The isolated adrenal atrophy occasionally observed after a median eminence lesion is explained on the basis of the time factor of the atrophy, which develops much quicker in the adrenal than, especially, in the male gonad."

Vernikos-Danellis, J.: "Quantitative changes in corticotropin releasing activity of rat hypothalamus and neurohypophysis after stress." *Program 45th Meet. Endocrinol. Soc.*, pp. 28-29. New York, 1963.

E20,839/63

In rats the ME is particularly rich in CRF, and adrenalectomy further elevates it. Ether anesthesia in adrenalectomized rats causes an additional rise within 1.25 minutes. The CRF activity of hypothalamic tissue outside the ME is comparatively low. "It is concluded that the median eminence is the major source of CRF and that it responds to stress in a manner that parallels changes in pituitary ACTH."

Krieger, D. T., Krieger, H. P.: "The effects of intrahypothalamic injection of drugs on ACTH release in the cat." Proc. 2nd Int. Congr. Endocrinol., London, 1964, Part 1. *Int. Congr. Ser. No. 83*, pp. 640-645. Amsterdam and New York: Excerpta Medica, 1964.

F48,895/64

In cats, implantation of cholinergic or adrenergic drugs (5-HT or GABA) in the ME and various adjacent regions shows that different neurons of the hypothalamus are selectively sensitive to diverse substances, and that the same drug applied to different sites produces different results, especially as regards ACTH release. It is suggested that not neurons but synapses are stimulated.

Fortier, C., Groot, J. de: "Residual synthesis and release of ACTH following electrolytic destruction of the median eminence in the rat." In: Bajusz, E. and Jasmin, G., *Major Problems in Neuroendocrinology*, pp. 203-219. Basel and New York: S Karger, 1964.

E3,995/64

In rats, immediately following electrolytic destruction of the ME, there is a temporary increase in plasma ACTH that is probably initiated during the stress of the operation. Plasma corticosterone then falls and stabilizes at a subnormal level, probably owing to the disappearance of CRF and to adenohypophyseal ischemia (yet its level remains somewhat above that of hypophysectomized animals). The adenohypophyseal weight is decreased, yet following the transitory fall, its ACTH content rises above normal within one week, subsequently dropping to subnormal levels. Eventually, "the synchronized rates of synthesis and release are interpreted as evidence that residual corticotrophic activity is compatible with the exclusion of hypothalamic influence presumably achieved by complete destruction of the bulbus of the Median Eminence" (20 refs.).

Fortier, C., Groot, J. de: "Effect of localized destruction of the ventral hypothalamus on the adrenocorticotrophic responses to sur-

gical trauma and to hypocorticoidism in the rat." In: Bajusz, E. and Jasmin, G., *Major Problems in Neuroendocrinology*, pp. 220-229. Basel and New York: S Karger, 1964.

E3,996/64

In rats, stimulation of ACTH secretion by unilateral or bilateral adrenalectomy was suppressed following electrolytic destruction of the bulbous portion of the ME or of premammillary and mammillary structures. It is concluded that the hypothalamus plays an essential role in the mediation of ACTH secretion during stress and hypocorticoidism.

Fuxe, K.: "Cellular localization of monoamines in the median eminence and the infundibular stem of some mammals." *Z. Zellforsch. Mikrosk. Anat.* **61**: 710-724 (1964).

G2,752/64

In various mammals the ME is particularly rich in fluorescence microscopy-demonstrable monoamines, especially in the terminal parts of nonsympathetic nerve fibers that converge upon the portal system. "The findings indicate that primary catecholamines are released to the primary plexus of the hypophyseal portal system and thus transported to the anterior lobe. These amines may consequently act as neuro-humoral transmitters for the regulation of the activity of the anterior pituitary.—No direct adrenergic innervation of the cells in the pars tuberalis and anterior lobe was found. The portal vessels in the pars tuberalis receive a very sparse adrenergic innervation, and the vessels in the anterior lobe receive no or very few adrenergic nerves."

Röhlich, P., Vigh, B., Teichmann, I., Aros, B.: "Electron microscopy of the median eminence of the rat." *Acta Biol. Acad. Sci. Hung.* **15**: 431-457 (1965).

J12,740/65

EM studies of the ependymal cells in the region of the ME suggest that they may have a secretory function (30 refs.).

Duffy, P. E., Menefee, M.: "Electron microscopic observations of neurosecretory granules, nerve and glial fibers, and blood vessels in the median eminence of the rabbit." *Am. J. Anat.* **117**: 251-286 (1965).

J12,741/65

Vernikos-Danellis, J.: "Effect of stress,

adrenalectomy, hypophysectomy and hydrocortisone on the corticotropin-releasing activity of rat median eminence." *Endocrinology* **76**: 122-126 (1965).

G32,998/65

In rats, the CRF content of the ME begins rising five days after adrenalectomy and reaches a peak after twenty days. Hypophysectomy does not influence it, whereas the stress of ether anesthesia markedly increases the ACTH-releasing activity within less than two minutes in normal, adrenalectomized or hypophysectomized rats. Cortisol drastically reduces CRF activity and prevents the rise caused by stress. "It is suggested that the close parallelism between the changes occurring in the median eminence and pituitary under these conditions indicates that CRF may regulate pituitary ACTH synthesis."

D'Angelo, S. A., Young, R.: "Chronic lesions and ACTH: effects of thyroid hormones and electrical stimulation." *Am. J. Physiol.* **210**: 795-800 (1966).

F63,559/66

In rats with chronic ME lesions, T₃ and T₄ increased adrenal weight without correcting pituitary and ovarian atrophy, decreased adrenal and ovarian ascorbic acid contents, and elevated plasma and adrenal corticoids. Electric stimulation of the anterior hypothalamus in intact rats caused ACTH release, and this was blocked by ME lesions. Basal ACTH secretion following destruction of the ME remains appreciable and can be enhanced by hyperthyroidism. Presumably, "neural stimuli from the rostral hypothalamus mediate their effects on ACTH release via the median eminence; and augmentation of ACTH secretion in severe hyperthyroidism involves a non-neural, humoral metabolic pathway."

Rinne, U. K., Arstila, A. U.: "Ultrastructure of the neurovascular link between the hypothalamus and anterior pituitary gland in the median eminence of the rat." *Neuroendocrinology* **1**: 214-227 (1965-66).

F68,590/65-66

Rinne, U. K.: "Ultrastructure of the median eminence of the rat." *Z. Zellforsch. Mikrosk. Anat.* **74**: 98-122 (1966).

F81,565/67

Various experiments suggest that the inability of rats with lesions in the ME to

respond to stressors by an increased discharge of ACTH (as evidenced by corticosterone blood levels) results from failure "to secrete CRF and is not due to deficiencies in pituitary blood flow, that the activity of the pituitary-adrenocortical system varies directly with CRF output, and that CRF is involved in the minute-to-minute regulation of ACTH secretion" (25 refs.).

Akmayev, I. G., Réthelyi, M., Majorossy, K.: "Changes induced by adrenalectomy in nerve endings of the hypothalamic median eminence (Zona palisadica) in the albino rat." *Acta Biol. Acad. Sci. Hung.* **18**: 187-200 (1967). G48,945/67

Description of the structural changes produced by adrenalectomy in the ME of the rat. These probably reflect an increased discharge of CRF.

Monroe, B. G.: "A comparative study of the ultrastructure of the median eminence, infundibular stem and neural lobe of the hypophysis of the rat." *Z. Zellforsch. Mikrosk. Anat.* **76**: 405-432 (1967).

G44,280/67

Kobayashi, T., Kobayashi, T., Yamamoto, K., Kaibara, M., Ajika, K.: "Electron microscopic observation on the hypothalamo-hypophyseal system in the rat. III. Effect of reserpine treatment on the axonal inclusions in the median eminence." *Endocrinol. Jap.* **15**: 321-335 (1968). H4,331/68

In rats, EM studies of the ME revealed an increase in electron-dense large granules (thought to be carriers of neurohypophyseal hormones) and a decrease in small granules (presumably carriers of catecholamines) after reserpine treatment.

Porter, J. C.: "Site of corticotropin-releasing factor (CRF) releasing elements: effect of lesions on ACTH release and adenohypophyseal blood flow." *Endocrinology* **84**: 1398-1403 (1969). H13,663/69

In rats, electrolytic lesions in the pituitary stalk and ME completely suppressed ACTH release after surgical trauma throughout the seventy-minute-period of observation, whereas lesions in the anterior ME slowed the rate of ACTH discharge only temporarily. Apparently the CRF-secreting elements are located in the pituitary stalk and/or near its junction with the ME (27 refs.).

Chan, L. T., Wied, D. de, Saffran, M.: "Comparison of assays for corticotrophin-

releasing activity." *Endocrinology* **84**: 967-972 (1969). H11,041/69

In rats with electrolytic lesions in the ME, three assay methods for CRF in vivo and in vitro were tested following vasopressin injection.

Kobayashi, H., Matsui, T.: "Fine structure of the median eminence and its functional significance." In: Ganong, W. F. and Martini, L., *Frontiers in Neuroendocrinology*, pp. 3-46. New York, London and Toronto: Oxford University Press, 1969. E10,612/69

Rodríguez, E. M.: "Ependymal specializations. I. Fine structure of the neural (internal) region of the toad median eminence, with particular reference to the connections between the ependymal cells and the subependymal capillary loops." *Z. Zellforsch. Mikrosk. Anat.* **102**: 153-171 (1969).

G72,035/69

In toads, an anatomic arrangement connecting the specialized ependymal cells of the ME with the long loops of the primary plexus in the pituitary-hypophyseal system "makes the possibility of an interrelationship between the cerebrospinal fluid and the portal blood very considerable." Earlier literature concerning such specialized ependymal cells is extensively reviewed.

Voitkevich, A. A., Dedov, I. I.: "Neurovascular contacts of the median eminence of the neurohypophysis." *Dokl. Akad. Nauk SSSR* **186**: 373-376 (1969) (English trans. of Russian original). J13,889/69

Réthelyi, M., Halász, B.: "Origin of the nerve endings in the surface zone of the median eminence of the rat hypothalamus." *Exp. Brain Res.* **11**: 145-158 (1970).

J10,894/70

In rats, various hypothalamic areas were partially or totally separated from the brain by means of a stereotactically manipulated bayonet-shaped knife, and the zona palisadica was examined for degeneration of axon terminals under the EM. It was found that "the nerve terminals in the zona palisadica arise exclusively from neurons in the medial basal hypothalamus, and that fibers of other origin do not terminate in this zone. The present observations support the assumption that the hypothalamic releasing (and inhibiting) factors are produced by, and the neural control of the anterior pituitary is exercised over a short final neuronal link, localized in the medial basal hypothalamus." These findings again confirm that the zona palisadica of the

ME and the proximal part of the pituitary stalk play key roles in the neurohumoral control of the adenohypophysis.

Brown, G. M., Schalch, D. S., Reichlin, S.: "Hypothalamic mediation of growth hormone and adrenal stress response in the squirrel monkey." *Endocrinology* **89**: 694-703 (1971). H45,128/71

In squirrel monkeys the stress of emotional excitement (chair restraint, capture) increases plasma STH and corticoid levels, but the two changes do not run parallel. The STH response to capture and ether was blocked by small lesions either in the anterior or posterior ME, while the adrenal responses to capture and chair restraint were blocked by lesions in the posterior ME. The STH responses to ether were enhanced by midline optic chiasm lesions. However, great individual variations interfered with the precise evaluation of these data.

Takebe, K., Kunita, H., Sakakura, M., Horiuchi, Y., Mashimo, K.: "Suppressive effect of dexamethasone on the rise of CRF activity in the median eminence induced by stress." *Endocrinology* **89**: 1014-1019 (1971). H47,039/71

In rats, dexamethasone blocked stress-induced (surgery) rises in the CRF level of the ME and in the plasma corticosterone concentration. The pituitaries of dexamethasone-treated rats responded to ME extract in a normal manner. It is concluded that dexamethasone-induced inhibition acts mainly at or above the hypothalamic level.

Fink, G., Smith, G. C.: "Ultrastructural features of the developing hypothalamo-hypophysial axis in the rat. A correlative study." *Z. Zellforsch. Mikrosk. Anat.* **119**: 208-226 (1971). G85,999/71

EM studies on the fetal ME of the rat. The finding that "the development of granular vesicles precedes that of agranular vesicles is discussed with reference to the times at which neurosecretory materials and monoamines become detectable in the region."

Knigge, K. M., Scott, D. E., Weindl, A. (eds.): *Brain-Endocrine Interaction. Median Eminence: Structure and Function*, p. 368. Basel and New York: S Karger, 1972.

E10,204/72

Proceedings of a congress dealing with all aspects of the ME, including its embryonic development, histology, ultrastructure, the various agents that influence it, and its prob-

able function as a neuroendocrine organ in different species (numerous refs.).

Halász, B., Kosaras, B., Lengvári, I.: "Ontogenesis of the neurovascular link between the hypothalamus and the anterior pituitary in the rat." In: Knigge, K. M., Scott, D. E. et al., *Brain-Endocrine Interaction. Median Eminence: Structure and Function*, pp. 27-34. Basel and New York: S Karger, 1972. J17,773/72

Monroe, B. C., Newman, B. L., Schapiro, S.: "Ultrastructure of the median eminence of neonatal and adult rats." In: Knigge, K. M., Scott, D. E. et al., *Brain-Endocrine Interaction. Median Eminence: Structure and Function*, pp. 7-26. Basel and New York: S Karger, 1972. J17,772/72

E10,558/72

Studies using various techniques in the mink and rat suggest that the ME is dynamically active and controls several aspects of hormonal feedback. Both *in vivo* and *in vitro*, it exhibits a high metabolic activity and a great capacity to accumulate thyroxine injected into the CSF, and then to release it into the portal circulation, whence it is transmitted to the adenohypophysis. TTH and dopamine significantly affect thyroxine uptake.

Dedov, I. I.: "Median eminence of neurohypophysis under extreme conditions." *Dokl. Akad. Nauk SSSR* **204**: 1503-1506 (1972) (Russian). Engl. trans.: *Proc. Acad. Sci. USSR, Biol. Sci.* **204**: 298-301 (1972).

J20,136/72

EM changes in the rat hypophysis following exposure to various stressors or metyrapone.

Smith, G. C., Helme, R. D.: "Ultrastructural and fluorescence histochemical studies on the effects of 6-hydroxydopamine on the rat median eminence." *Cell Tissue Res.* **152**: 493-512 (1974). J18,969/74

In the ME of the rat, regeneration of catecholamine-containing neurons is almost complete within three weeks after treatment with intravenous 6-hydroxydopamine. [This fact should be remembered in studies on the role of the ME in stress reactions (H.S.).]

Watkins, W. B., Schwabedal, P., Bock, R.: "Immunohistochemical demonstration of a CRF-associated neurophysin in the external zone of the rat median eminence." *Cell Tissue Res.* **152**: 411-421 (1974). J18,966/74

"In normal rats, 'Gomori-positive' substances and neurophysin were confined to the internal zone of the median eminence. After adrenalectomy, however, 'Gomori-positive' granules and a neurophysin-like protein also became apparent in the external zone. Their amount increases, if the animals are treated with DOCA from the 15th to the 21st day after the operation. The distribution of the neurophysin-like protein in the external zone is similar to that of the 'Gomori-positive' granules." The latter are regarded as morphologic correlates of CRF. Since they cross-react with neurophysin antiserum, the name "CRF-neurophysin" is proposed.

Gouget, A., Duvernoy, J., Bugnon, C.: "Recherches sur la participation du tractus infundibulaire dopaminergique dans le fonctionnement de l'axe corticotrope" (Investigation on the participation of the dopaminergic infundibular tract in the activity of the corticotrophic axis). *Bull. Assoc. Anat. (Nancy)* **58**: 315-322 (1974). J17,278/74

By use of the Falck-Hillarp histochemical fluorescence method, an important decrease in monoamines was demonstrated fifteen days after adrenalectomy in the ME of the rat. This decrease indicates a diminution of dopamine in the terminals of the infundibular tract. "A kinetic study of the rate of MA [monoamine] depletion in control and adrenalectomized rats, treated by α -MT, confirms an accelerated turnover and an important discharge of DA with CRF release in the portal vessels."

Dunn, J., Arimura, A.: "Serum growth hormone levels following ablation of medial basal hypothalamus." *Neuroendocrinology* **15**: 189-199 (1974). H91,993/74

In rats with large medial hypothalamic lesions, STH secretion after "ether stress" was impaired but not abolished. (The destruction was accomplished by a modified Halász knife with a cross bar which interrupted the vascular supply from the ventral surface of the brain.) Perhaps the simultaneous elimination of stimulation and inhibition by neural impulses largely compensated for the effect upon STH release. "The pituitary somatotrophs appear capable of autonomous secretion."

Schwabedal, P. E.: "Influence of stress on the amount of 'Gomori-positive' granules in the outer layer of the median eminence of bilaterally adrenalectomized rats." *J. Neural. Transm.* **35**: 217-231 (1974). J17,427/74

In rats, various stressors (formaldehyde, histamine, endotoxins) diminish the number of "Gomori-positive" granules in the ME, reflecting the release of CRF.

Knigge, K. M., Silverman, A. J.: "Anatomy of the endocrine hypothalamus." In: Greep, R. O. and Astwood, E. B., *Handbook of Physiology. Section 7, Endocrinology*, Vol. IV, Part 1, pp. 1-32. Washington, D. C.: American Physiological Society, 1974.

E10,721/74

Excellent review on the fine structure of the hypothalamus, with a special section on the catecholamine content of the ME during stress.

Medulla Oblongata, Pons, Locus Coeruleus

(See also our earlier stress monographs, p. xiii)

Gibbs, F. P.: "Area of pons necessary for traumatic stress-induced ACTH release under pentobarbital anesthesia." *Am. J. Physiol.* **217**: 84-88 (1969). H14,557/69

From observations on rats with lesions in the pons produced under pentobarbital anesthesia and tibial fractures ten days later, it was concluded that "there is an area in the pontine reticular formation which facilitates the traumatic stress-induced release of ACTH..." Only lesions in the pontine reticular formation block ACTH significantly, although destruction of other areas also causes slight inhibition.

Belova, T. I., Bunkina, L. S.: "Catecholamines of the oral region of the brain stem under normal conditions and during rapidly developing stress. (Histochemical investigation)." *Biull. Èksp. Biol. Med.* **70**: No. 12: 93-96 (1970) (Russian). Engl. trans.: *Bull. Exp. Biol. Med.* **70**: 1438-1441 (1970).

J21,614/70

In mice, the stress of asphyxia changed the histochemical distribution of catecholamines in the "locus coeruleus; substantia nigra; grisea centralis, and adjacent ventrolateral portions of the mesencephalic reticular formation; the region of the raphé; ganglion interpedunculare, together with regions lying laterally to it."

Bubenik, G., Monnier, M.: "Nuclear size variations in cells of the locus ceruleus during sleep, arousal and stress." *Exp. Neurol.* **35:** 1-12 (1972). G90,134/72

Korf, J., Aghajanian, G. K., Roth, R. H.: "Increased turnover of norepinephrine in the rat cerebral cortex during stress: role of the locus coeruleus." *Neuropharmacology* **12:** 933-938 (1973). J21,582/73

"The noradrenergic nerve terminals in the rat cerebral cortex are mainly supplied by norepinephrine-containing neurones originating in the locus coeruleus." Stress increases the turnover of NEP in this location. Apparently, "the locus coeruleus plays an important role in mediating the effect of stress on the metabolism of norepinephrine in the cerebral cortex."

Roussel, B., Cure, M., Renaud, B., Valatx, J.-L.: "Hypertrophie surrénalienne après lésion des neurones catécholaminergiques pontiques, chez le Rat" (Adrenal hypertrophy after lesion of the catecholaminergic pontine neurons in the rat). *C.R. Acad. Sci. [D]* (Paris) **277:** 1897-1900 (1973).

J28,455/73

In rats, destruction of the locus coeruleus and subcoeruleus causes temporary hyperplasia of the fasciculata in the adrenal cortex. This is of interest since the noradrenergic neurons with hypothalamic projections are located in the locus coeruleus, and destruction of this center suppresses the blocking effect of NEP on hypothalamic or pituitary inhibitors.

Ögren, S. O., Fuxe, K.: "Learning, brain noradrenaline and the pituitary-adrenal axis." *Med. Biol.* **52:** 399-405 (1974).

J24,846/74

In rats, the NEP pathways to the forebrain were destroyed by the injection of 6-hydroxy-dopamine (6-OH-DA) into the coeruleo-cortico (dorsal) bundle without significantly impairing retention of the conditioned avoidance response (CAR). However, when 6-OH-DA lesions were combined with adrenalectomy, "there was a marked reduction of the retention of CAR and a complete failure to relearn the CAR."

Peripheral Nerves

(See also our earlier stress monographs, p. xiii)

Cannon, W. B.: "The stimulation of adre-

nal secretion by emotional excitement." *Proc. Am. Phil. Soc.* **1:** 226-227 (1911).

35,529/11

Cannon, W. B.: "The emergency function of the adrenal medulla in pain and the major emotions." *Am. J. Physiol.* **33:** 356-372 (1914). 57,873/14

Review of the earliest animal experiments showing that fear, rage, asphyxia and pain cause the discharge of EP from the adrenal medulla, and that this response is mediated through the splanchnic nerves. Direct stimulation of the latter exerts the same effect. The resulting glycogenolysis and increase in blood sugar furnish energy. At the same time, blood circulation is improved. Stimulation of the splanchnics also hastens blood coagulation and thereby protects against bleeding in the event of injury. All these changes are "directly serviceable in making the organism more efficient in the struggle which fear or rage or pain may involve."

Rydin, H., Verney, E. B.: "The inhibition of water-diuresis by emotional stress and by muscular exercise." *Q. J. Exp. Physiol.* **27:** 343-374 (1938). A14,575/38

In dogs, emotional excitement and muscular exercise inhibit diuresis. This response is unaltered by transection of the renal nerves, by extirpation of one adrenal and denervation of the other, or by decentralization of the whole abdominal sympathetic system with ablation of ganglia L2 to S1 inclusive. The course of this inhibition is matched by vasopressin. "The post-pituitary equivalent of this stress in terms of the standard powder is of the order of 1 µg."

Vogt, M.: "Cortical lipids of the normal and denervated suprarenal gland under conditions of stress." *J. Physiol. (Lond.)* **106:** 394-404 (1947). B26,537/47

In rats and cats, repeated injections of EP cause conspicuous degranulation of the adrenal cortical cells, which is ascribed to stress and cannot be prevented by adrenal denervation.

Gordon, M. L.: "An evaluation of afferent nervous impulses in the adrenal cortical response to trauma." *Endocrinology* **47:** 347-350 (1950). B48,953/50

In adrenal-demedullated rats, adrenal ascorbic acid discharge following fracture or a mild burn to the leg was diminished by denervation of the injured extremity. This was not the case after severe scalding.

Ray, B. S., Console, A. D.: "Bodily adjustments in man during stress in the absence of most visceral afferents and sympathetic nervous system regulation." In: Wolff, H. G., Wolf, S. G. Jr., et al., *Life Stress and Bodily Disease*, pp. 114-120. Baltimore: Williams & Wilkins, 1950. B51,898/50

"Total sympathectomy in man imposes great limitations on his response to stress of all types but at the same time protects him from certain destructive effects of emotional stress."

Hume, D. M., Nelson, D. H.: "Adrenal cortical function in surgical shock." *Surg. Forum* 5: 568-575 (1954). E40,942/54

In dogs, increased 17-OHCS output into the adrenal blood under the influence of trauma or hemorrhage does not depend upon the integrity of the nerves supplying the adrenal medulla.

Greer, M. A.: "Studies on the influence of the central nervous system on anterior pituitary function." *Rec. Prog. Horm. Res.* 13: 67-98 (1957). C38,181/57

Brodie, D. A., Hanson, H. M.: "A study of the factors involved in the production of gastric ulcers by the restraint technique." *Gastroenterology* 38: 353-360 (1960). C87,271/60

Bilateral subdiaphragmatic vagotomy did not significantly reduce the incidence of restraint ulcers in the rat.

Menguy, R.: "Effects of restraint stress on gastric secretion in the rat." *Am. J. Dig. Dis.* 5: 911-916 (1960). C93,988/60

"Previously vagotomized rats were partially protected from stress [restraint] ulcers whereas hypophysectomy or adrenalectomy were without effect" (13 refs.).

Nauta, W. J. H.: "Central nervous organization and the endocrine motor system." In: Nalbandov, A. V., *Advances in Neuroendocrinology*, pp. 5-21. Urbana, Ill.: University of Illinois Press, 1963. J12,286/63

Review on the influence of various nervous structures (hypothalamus, limbic forebrain, limbic system-midbrain circuit) on behavior, "vital feelings," "behavioral attitude" (angry, anxious, predatory or relaxed), as well as on the response to stressors (traumatic injuries, hypoxia), especially in relation to hormonal regulation (43 refs.).

Colehour, J. K., Graybiel, A.: "Excretion of 17-hydroxycorticosteroids, catechol amines, and uropepsin in the urine of normal persons

and deaf subjects with bilateral vestibular defects following acrobatic flight stress." *Aerosp. Med.* 35: 370-373 (1964).

G11,705/64

Deaf persons with vestibular defects accompanying experienced pilots on acrobatic flights failed to show the usual increase in corticoids and catecholamines, presumably because their appropriate sensory organs in the inner ear were not functional.

Lissák, K., Endrőczi, E.: *The Neuroendocrine Control of Adaptation*, p. 180. Oxford, New York and Paris: Pergamon Press, 1965.

E6,042/65

Slightly updated English version of a book originally published in German, briefly summarizing all aspects of hormonal and nervous influences during adaptation and correlating the work of I. P. Pavlov and W. B. Cannon with the nonspecific adaptive processes characteristic of the G.A.S.

Djahanguiri, B., Sadeghi, D., Hemmati, S.: "Système orthosympathique et ulcères gastriques expérimentaux" (The orthosympathetic system and experimental gastric ulcers). *Arch. Int. Pharmacodyn. Ther.* 173: 154-161 (1968). F99,278/68

In rats, cold increases the ulcerogenic effect of restraint, whereas α -adrenergic blocking agents prevent it.

Saito, A.: "Autoadaptation mechanism of the human body." *Tohoku J. Exp. Med.* 102: 289-312 (1970). H36,779/70

Review of the literature and theoretical considerations on the relationship between the G.A.S. and the vegetative nervous system, with special reference to Japanese publications (39 refs.).

Shum, A., Johnson, G. E., Flattery, K. V.: "Catecholamine and metabolite excretion in cold-stressed immunosympathectomized rats." *Am. J. Physiol.* 221: 64-68 (1971).

H41,823/71

Immunosympathectomy did not prevent the increase in NEP secretion produced in the rat by exposure to cold. However, when compared with untreated littermates, the immunosympathectomized rats excreted slightly less NEP and normetanephrine, and considerably less 3-methoxy-4-hydroxyphenylethylene glycol (MHPG). "It is postulated that a decreased sympathetic reserve in these animals caused a higher percentage of norepinephrine synthesized to be secreted as such, causing the lower MHPG excretion."

Van-Toller, C., Tarpy, R. M.: "Effect of cold stress on the performance of immunosympathectomized mice." *Physiol. Behav.* **8**: 515-517 (1972). G90,601/72

The results of escape-avoidance behavior in immunosympathectomized mice confined in a cold chamber "question previous generalizations concerning the role of the peripheral sympathetic nervous system in aversively motivated behavior."

J10,153/73

Review of the sympathoadrenal participation in stress, with personal observations "on cardiac infarct patients, normal and toxæmic pregnant subjects and on subjects undergoing various forms of athletic stress."

Delft, A. M. L. van, Nyakas, C., Kaplanski, J., Tilders, F. J. H.: "The effect of 6-hydroxydopamine administration to neonatal rats on some endocrine and behavioral parameters." *Arch. Int. Pharmacodyn. Ther.* **206**: 403-404 (1973). H82,629/73

Depletion of catecholamines in the rat brain, achieved by 6-hydroxydopamine, caused severe anorexia with impairment of growth and delayed vaginal opening, but curiously the stressor activity of the pituitary-adrenal system did not appear to be significantly affected. "Adrenal weights were normal when expressed per 100 g body weight. Diurnal peak and trough activities of adrenocortical activity as determined by measuring both plasma corticosterone levels and corticoid production of excised adrenal tissue in vitro were comparable to the activities found in control rats. Also the response of the pituitary-adrenal system when animals were exposed to strange environment or ether stress was completely within the normal range. These findings raise serious doubts with regard to the theory of the existence of a noradrenergic inhibitory system acting on pituitary-adrenal regulatory processes in the brain."

Dobkin, A. B., Pieloch, P. A.: "The metabolic effects of neuroleptanesthesia." *Int. Anesthesiol. Clin.* **11**: 155-169 (1973).

J9,286/73

Brief résumé of the literature and per-

sonal observations on the metabolic changes associated with anesthesia, particularly neuroleptanesthesia, in man. The changes in blood sugar, plasma cortisol, catecholamines, and so on were clearly characteristic of systemic stress. Furthermore, in the case of concurrent surgical interventions, "balanced anesthesia, with or without the neuroleptic component, does not block the stress response. Associated rises in blood sugar, plasma cortisol, and catecholamines during anesthesia and surgery appear to be well documented" (31 refs.).

Leduc, J.: "Effet de la sympathectomie chez le rat exposé au froid" (Effect of sympathectomy on rats exposed to cold). *Ann. ACFAS* **40**: 128 (1973). H87,897/73

6-Hydroxydopamine, which causes a "chemical sympathectomy," greatly diminishes resistance to cold. There is a marked rise in urinary EP but not NEP. Apparently, the adrenal medulla can largely compensate for the loss of sympathetic nerve activity.

Orlandi, F., Serra, D.: "La risposta ipotalamo-ipofisaria all'elettrostimolazione del nervo olfattivo" (Hypothalamo-hypophyseal reaction to electric stimulation of the olfactory nerve). *Folia Endocrinol. (Roma)* **26**: 441-446 (1973). H83,463/73

In man, direct electric stimulation of the nasal mucosa elicits rapid increases in plasma cortisol with other manifestations of stress, presumably because the olfactory nerve is directly connected with the CRF-producing hypothalamic centers.

Valdman, A. V.: "Functional and neurochemical analysis of visceral reactions related to emotional stress." *Proc. Satellite Symp. Emotions and Visceral Functions*, pp. 56-59. Baku, USSR, 1974 (Russian, with extensive English summary). J17,539/74

Vedyayev, F. P.: "Emotional stress condition models and their visceral manifestations." *Proc. Satellite Symp. Emotions and Visceral Functions*, pp. 62-67. Baku, USSR, 1974 (Russian, with extensive English summary). J17,541/74

Schumpelick, V., Paschen, U.: "Vergleich der protektiven Wirkung von Diazepam und Vagotomie auf das Stressulkus der Ratte" (Comparison of the protective activity of diazepam and vagotomy on stress ulcers in rats). *Arzneim. Forsch.* **24**: 176-179 (1974). H82,750/74

In rats, stress ulcers produced by restraint

can be partially prevented by diazepam pre-treatment or vagotomy, but combined application of both agents offers the best protection. "This fact demonstrates a different mode of action. The antiulcerative effect of diazepam is explained by its direct action on the vegetative regulation centres in the hypothalamic and limbic system, leading to a partial inhibition of the vagally controlled HCl-pepsin component and the splanchnic nerve dependent vascular factor of ulcerogenesis as well."

Carson, V. G., Wenzel, B. M.: "Tele-metered heart rates of immunosympathectomized and/or adrenal-medullectomized mice during behavioral tasks." *J. Comp. Physiol. Psychol.* **87**: 449-457 (1974). J16,524/74

Schumpelick, V., Kauffmann-Mackh, G.: "Der Einfluss des N. Vagus auf die Ulkusentstehung bei portokavaler Anastomose der Ratte" (The influence of the vagus nerve on ulcer formation in rats with portacaval anastomosis). *Brun's Beitr. Klin. Chir.* **221**: 239-246 (1974). J13,241/74

In rats with portacaval anastomosis, multiple ulcers occurred following pylorus ligation because of vagal stimulation. This was largely inhibited by vagotomy, which also diminished the quantity and acidity of the gastric juice (32 refs.).

Reticular Formation, Reticular Activating System

(See also our earlier stress monographs, p. xiii)

Nauta, W. J. H., Kuypers, H. G. J. M.: "Some ascending pathways in the brain stem reticular formation." In: Jasper, H. H., Proctor, L. D. et al., *Reticular Formation of the Brain*, pp. 3-30. Boston: Little, Brown, 1958. J12,282/58

Detailed and well-illustrated review concerning the morphology of the brain stem reticular formation in cats, emphasizing that "long and short ascending projections to the medial region of the caudal midbrain could constitute pathways capable of activating endocrine and autonomic mechanisms such as those involved in the stress response."

Harris, G. W.: "The reticular formation, stress and endocrine activity." In: Jasper, H. H., Proctor, L. D. et al., *Reticular Forma-*

tion of the Brain, pp. 207-221. Boston: Little, Brown, 1958. C78,255/58

Review of the literature showing that stressors, especially those causing increased EP, vasopressin and ACTH secretion, as well as decreased TTH secretion, probably act through the reticular activating system, which is closely related to, and has many characteristics in common with, the hypothalamus-hypophyseal system (57 refs.).

Royce, P. C., Sayers, G.: "Blood ACTH: effects of ether, pentobarbital, epinephrine and pain." *Endocrinology* **63**: 794-800 (1958). C61,941/58

In rats, painful stimuli markedly elevate blood ACTH within a few minutes. "Ether first excites, then inhibits ACTH release. Pentobarbital exhibits only a depressant action. The excitatory action of ether is blocked by decerebration and by destruction of the median eminence area of the hypothalamus. The excitatory action of epinephrine is manifest in the decerebrate but not in the median eminence lesioned rat. Since ether and pentobarbital depress the brain stem reticular system, it is reasonable to speculate that the action of these two agents in inhibiting ACTH release involves this multisynaptic conduction system."

Feldman, S., Heide, C. S. van der, Porter, R. W.: "Evoked potentials in the hypothalamus." *Am. J. Physiol.* **196**: 1163-1167 (1959). C70,825/59

Following electric stimulation of the sciatic nerve in cats, "the hypothalamic evoked potentials had a very prolonged recovery time on double stimulation, were sensitive to pentobarbital even to a greater degree than the evoked potentials in the midbrain reticular formation, and were abolished by high frequency stimulation of the midbrain reticular formation. The long latency potentials in the hypothalamus were similar to those evoked in the midbrain reticular formation, while the short latency potentials had properties similar to those of the lemniscal potentials. This fact suggested that the short latency potentials signaled the arrival of impulses from lemniscal collaterals."

Mazzone, R., Sozio, N., Padolecchia, N.: "Effetti della sensibilizzazione colinergica sulla sindrome reattiva allo 'stress'" (Effect of cholinergic sensitization on the syndrome reactive to "stress"). *Boll. Soc. Ital. Biol. Sper.* **36**: 157-159 (1960). J23,135/60

Cholinergic drugs increase reactivity to

pain-induced stress in the rabbit. These and other experiments with eserine and atropine suggest that the stress reaction develops in a zone sensitive to acetylcholine but not to atropine, and thus furnishes indirect evidence of the role of this reticular formation in the organization of defense mechanisms.

Welch, B. L.: "Psychophysiological response to the mean level of environmental stimulation: A theory of environmental integration." *Proc. Symp. Medical Aspects of Stress in the Military Climate*, pp. 39-99 (1965). G41,327/65

Review on the relationship between stress and the Mean Level of Environmental Stimulation (MLES). Detailed survey of the literature and personal observations on the effects of isolation with sensory deprivation or crowding on nonspecific responsiveness. Particular attention is given to the influence of the Ascending Reticular Activating System (ARAS) upon the hypothalamus and through it upon ACTH, glucocorticoid and catecholamine discharges. The numerous feedbacks in several mechanisms involved in arousal and relaxation are critically analyzed (205 refs.).

Kuntsevich, M. V.: "The effect of reticular formation of the mesencephalon on the hormone formation in the adrenal cortex in stress." *Probl. Endokrinol.* **13** No. 2: 61-64 (1967) (Russian). F78,769/67

In rats with electrolytic lesions in the reticular formation of the mesencephalon, the stress of surgical trauma failed to stimulate corticoid production.

Taylor, A. N.: "The role of the reticular activating system in the regulation of ACTH secretion." *Brain Res.* **13**: 234-246 (1969). H27,699/69

In cats, electric stimulation of the pontine and mesencephalic reticular formations caused "sustained cortical arousal, pupillary dilatation and a humorally mediated pressor response resulted in facilitation or inhibition of ACTH release commencing within 5 min after a 30-sec stimulation, reaching a maximum or minimum at 15 min and lasting 30-40 min. The direction of the ACTH response was dependent upon prestimulation levels of cortisol secretion. When these were low, facilitatory responses occurred, when high, inhibition or no change was observed" (28 refs.).

Cooper, C. J.: "Anatomical and physiological mechanisms of arousal, with special ref-

erence to the effects of exercise." *Ergonomics* **16**: 601-609 (1973). J8,261/73

Evidence suggesting that the stressor effect of exercise is at least partially mediated through an activation of the reticular formation.

Rhinencephalon (Archicortex)

(See also our earlier stress monographs, p. xiii)

Endrőczi, E., Lissák, K., Szép, C., Tígyi, A.: "Examinations of the pituitary-adrenocortical-thyroid system after ablation of neocortical and rhinencephalic structures." *Acta Physiol. Acad. Sci. Hung.* **6**: 19-31 (1954). C5,574/54

Working with cats, the authors "did not succeed in demonstrating an essential change in the adrenocortical function of animals with neocortical operation." In cats displaying a rage response, there was considerable exhaustion of lipid granules in the fasciculata, whereas the normally low lipid content of the reticularis tended to be increased. Blood corticoid levels also rose.

Slusher, M. A., Hyde, J. E.: "Inhibition of adrenal corticosteroid release by brain stem stimulation in cats." *Endocrinology* **68**: 773-782 (1961). D4,925/61

Review of the earliest literature on the enhancement or inhibition of ACTH secretion by stimulation or destruction of various parts of the CNS. In the present experiments, cats prepared as "encéphale isolés" exhibited a rapid decrease in adrenal venous corticoids following stimulation of the ventral midbrain tegmentum. Stimulation of the posterior diencephalon induced an increase, decrease, or no significant change in various cats. "An interrelationship between midbrain and diencephalic areas concerned with the regulation of ACTH release appears evident on the basis of reversals in corticosteroid levels in response to combined stimulation."

Endrőczi, E., Lissák, K.: "The role of rhinencephalon in the activation of the hypophyseoadrenocortico-gonad system and in the formation of emotional and sexual behavior" *Probl. Endokrinol. Gormonoter.* **7** No. 4: 18-26 (1961) (Russian, 34 refs.). D10,122/61

Septum

(See also our earlier stress monographs, p. xiii)

Usher, D. R., Ling, G. M., MacConaill, M.: "Some endocrine and behavioural effects of chlordiazepoxide in septal-lesioned rats." *Int. J. Clin. Pharmacol.* **1**: 191-196 (1968).

G64,766/68

Rats with septal lesions developed a typical behavioral pattern, the "septal syndrome," with enhanced ACTH synthesis, but diminished release of this hormone during stress. "Chlordiazepoxide reduced the hyper-reactivity of septal-lesioned rats, but had no effect on endocrine organ weights; the reduction of hyper-reactivity was more marked in the stressed animals. Lesioned rats had larger adenohypophyses than sham-operated animals. The weight of this gland was reduced in all stressed animals, whether sham-operated or lesioned. It is postulated that mild stress and chlordiazepoxide both contribute to a diminished hyper-reactivity of rats with septal lesions."

Kozlovskaya, M. M., Valdman, A. V.: "Behavioral and EEG reactions evoked by stimulation of the medial and lateral septal zones of the brain in the rabbit." *Zh. Vyssh. Nerv. Deyat.* **20**: 1022-1030 (1970) (Russian).
J21,849/70

Endrőczi, E., Nyakas, C.: "Effect of septal lesion on exploratory activity, passive avoidance learning and pituitary-adrenal function in the rat." *Acta Physiol. Acad. Sci. Hung.* **39**: 351-360 (1971). G87,966/71

"A possible role of the cessation of hippocampal-hypothalamic connections, on the one hand, and a selective corticosterone accumulation by the hippocampus, on the other hand, as events involved in behavioural changes after rostral septal lesion, are discussed."

Golda, V., Stránský, Z., Petr, R., Herink, J., Záková, Z.: "Brain serotonin in stressed, adrenalectomized and septal rats." *Activ. Nerv. Sup. (Praha)* **14**: 215-217 (1972).
J20,547/72

Brown, G. M., Uhlir, I. V., Seggie, J., Schally, A. V., Kastin, A. J.: "Effect of septal lesions on plasma levels of MSH, corticosterone, GH and prolactin before and after exposure to novel environment: role of MSH in the septal syndrome." *Endocrinology* **94**: 583-587 (1974). H86,300/74

In rats, septal lesions considerably altered hormonal reactions to various stressors, and concurrently there were pronounced behavioral changes. The literature on the "septal syndrome" is reviewed (26 refs.).

Usher, D. R., Lieblich, I., Siegel, R. A.: "Pituitary-adrenal function after small and large lesions in the lateral septal area in food-deprived rats." *Neuroendocrinology* **16**: 156-164 (1974). H98,364/74

Ladisch, W.: "Stress und Serotoninstoffwechsel in verschiedenen Arealen des Zentralnervensystems der Ratte" (Stress affecting the serotonin metabolism in different regions of the central nervous system in the rat). *Arzneim. Forsch.* **24**: 1025-1027 (1974).
H88,829/74

In rats, electric footshock caused a pronounced increase in 5-HIAA in the raphé and septum, whereas 5-HT concentrations rose mainly in the septum, thalamus and hypothalamus. In general, "septum and raphé appeared to be the regions whose 5-HT metabolism was mostly changed by the stress of electric footshock."

Seggie, J., Uhlir, I., Brown, G. M.: "Adrenal stress responses following septal lesions in the rat." *Neuroendocrinology* **16**: 225-236 (1974). H98,370/74

Uhlir, I., Seggie, J., Brown, G. M.: "The effect of septal lesions on the threshold of adrenal stress response." *Neuroendocrinology* **14**: 351-355 (1974). H89,268/74

In rats with septal lesions, "baseline corticosterone values were unaltered, plasma corticosterone concentrations in lesioned animals were elevated in response to stimuli that did not produce a corresponding elevation in sham-lesioned and unlesioned animals. Neither baseline nor stress levels of prolactin were affected by septal lesions at the times studied. It is concluded that a septal lesion lowers the stimulation threshold for activation of the pituitary adrenal axis and is suggested that corticosterone and prolactin stress responses are under different neural control."

Seggie, J., Shaw, B., Uhlir, I., Brown, G. M.: "Baseline 24-hour plasma corticosterone rhythm in normal, sham-operated and septally-lesioned rats." *Neuroendocrinology* **15**: 51-61 (1974). H89,697/74

In rats the circadian rhythm of plasma corticosterone is elevated after damage to

the septum under ordinary conditions, but not under rigorously controlled environmental isolation excluding any disturbing stressor stimuli. "Thus, the hypothesis is borne out that although the baseline adrenal function is normal in septally-lesioned rats, adrenal responses to stimulation are enhanced."

Kelsey, J. E.: "Role of pituitary-adrenocortical system in mediating avoidance behavior of rats with septal lesions." *J. Comp. Physiol. Psychol.* **88**: 271-280 (1975).

J20,817/75

through the interior of the stalk to the tuberal region."

Collin, R.: "Les fondements morphologiques de la notion de neurocrinie hypophysaire. Etat actuel de la question" (Morphologic basis of the notion of the hypophyseal "neurocrinie." Present state of the subject). *Ann. Physiol. Physicochim. Biol.* **10**: 953-962 (1934). 29,038/34

On the basis of purely morphologic observations, colloid granules in the pituitary are regarded as carriers of hormonal products that are microscopically detectable manifestations of secretions. Colloid can be formed in all parts of the gland, and appears to be discharged into the general circulation (hemocrinie), the CSF, (hydrencéphalocrinie), the tuber cinereum after traversing the neurohypophysis infundibulum (neurocrinie) and the hypophyseal portal vessels (hémoneurocrinie). The author still supports the view that the circulation through the portal vessels flows from the pituitary to the hypothalamus.

Westman, A., Jacobsohn, D.: "Endokrinologische Untersuchungen an Ratten mit durchtrenntem Hypophysenstiel. 5. Mitteilg. Verhalten des Wachstums, der Nebennieren und der Schilddrüsen" (Endocrinologic studies in rats with transection of the pituitary stalk. 5. Studies on somatic growth, adrenals, and thyroid). *Acta Pathol. Microbiol. Scand.* **15**: 435-444 (1938).

A17,898/38

In rats, transection of the pituitary stalk inhibits somatic growth and causes histologic evidence of thyroid inactivity, but the adrenals are not atrophic and fail to show the characteristic sudanophobe zone seen after hypophysectomy.

Uotila, U. U.: "On the role of the pituitary stalk in the regulation of the anterior pituitary, with special reference to the thyrotropic hormone." *Endocrinology* **25**: 605-614 (1939). A19,997/39

In rats, after transection of the pituitary stalk [without any measures to prevent vascular regeneration] the adrenal and thyroid structures remain essentially normal, but upon exposure to cold the adrenals show a typical hypertrophy of the alarm reaction, whereas the usual stimulation of the thyroid does not occur.

Green, J. D., Harris, G. W.: "The neurovascular link between the neurohypophysis

Stalk, Portal Vessels

(See also our earlier stress monographs, p. xiii, and cf. Hypothalamus and Thalamus)

Pietsch, K.: "Aufbau und Entwicklung der Pars tuberalis des menschlichen Hirnanhangs in ihren Beziehungen zu den übrigen Hypophysenteilen" (Anatomy and development of the human hypophyseal pars tuberalis, and its relationship to the other parts of the hypophysis). *Z. Mikrosk. Anat. Forsch.* **22**: 227-258 (1930). 5,087/30

Anatomic studies on the human pituitary indicate that the veins and capillaries of the anterior lobe and pars tuberalis carry blood upwards into the tuber cinereum, and that the histologically visible colloid they contain may represent a secretion of the glandular parts, "a secretory stream of the anterior lobe towards the hypothalamic centers."

Popa, G. T., Fielding, U.: "Hypophysio-portal vessels and their colloid accompaniment." *J. Anat.* **67**: 227-232 (1933).

29,759/33

After a brief résumé of earlier data on venous vessels in the pituitary stalk, personal observations on man are reported which suggest that the pituitary stalk and tuber region contain colloid in their vessels. This "colloid—whatever it may be—is formed in the pituitary and not in the brain, so that its association with the vessels may be taken as indicating that the direction of the flow is certainly hypophysio-hypothalamic." The authors discredit the earlier findings of Karl Pietsch who, on the basis of very similar observations, concluded that "the veins and the capillaries of the pars tuberalis are derived from the adenohypophysis.... They partly abut into the sinus circulatorius but most of them I see progressing

and adenohypophysis." *J. Endocrinol.* **5**: 136-146 (1947). B1,426/47

In the rabbit, monkey and man, nervous connections between the neuro- and adenohypophysis are scanty. Vascular connections are prominent in the rat, guinea pig, rabbit, dog and man, particularly between the capillary loops of the ME, infundibular stem and the hypophyseal portal vessels. These vessels are well supplied with nerve fibers. "It is suggested that the central nervous system regulates the activity of the adenohypophysis by means of a humoral relay through the hypophyseal portal vessels."

Green, J. D.: "Vessels and nerves of amphibian hypophyses. A study of the living circulation and of the histology of the hypophyseal vessels and nerves." *Anat. Rec.* **99**: 21-53 (1947). B4,690/47

Detailed description of the hypophyseal portal system in the bullfrog and *Ambystoma*.

Harris, G. W.: "The blood vessels of the rabbit's pituitary gland, and the significance of the pars and zona tuberalis." *J. Anat.* **81**: 343-351 (1947). B35,058/47

Merényi, D.: "Angioarchitektur der Katzenhypophyse. Morphologische Grundlagen zur experimentellen Forschung über das hypophyseo-diencephale System" (Angioarchitecture of the hypophysis in cats. Morphologic baseline for experimental investigations of the hypophyseal-diencephalic system). *Virchows Arch. [Pathol. Anat.]* **315**: 534-547 (1948). B27,100/48

Ink preparation injections indicate that in the cat the anterior lobe receives no arterial blood and is supplied only by the portal vessels descending from the pars tuberalis and the stalk. Consequently, transection of the stalk causes pituitary necrosis; hence this species is unsuitable for studies concerning results of severing the pituitary from the hypothalamus.

Green, J. D., Harris, G. W.: "Observation of the hypophyseal-portal vessels of the living rat." *J. Physiol. (Lond.)* **108**: 359-361 (1949). B32,936/49

A technique for the observation of hypophyseal-portal vessels in the living rat shows that the direction of the blood flow is from the ME to the pars distalis.

Harris, G. W.: "Regeneration of the hypophyseal portal vessels." *Nature* **163**: 70 (1949). B71,852/49

Cheng, C. P., Sayers, G., Goodman, L. S., Swinyard, C. A.: "Discharge of adrenocorticotropic hormone in the absence of neural connections between the pituitary and hypothalamus." *Am. J. Physiol.* **158**: 45-50 (1949). B38,333/49

In rats, pituitary stalk transection does not interfere with the normal adrenocortical response. "It is therefore concluded that the prompt release of adrenocorticotropic hormone from the adenohypophysis in response to stress is not dependent upon neural connections between the hypothalamus and the anterior pituitary." The authors are careful to point out that their findings "do not rule out the possibility that a neurohumor, arising in the hypothalamus and passing to the adenohypophysis via a hypophyseal portal system, mediates the release of ACTH in response to the application of stress."

Harris, G. W., Johnson, R. T.: "Regeneration of the hypophyseal portal vessels, after section of the hypophyseal stalk, in the monkey (*Macacus rhesus*)."*Nature* **165**: 819 (1950). B71,853/50

Harris, G. W.: "Oestrous rhythm. Pseudopregnancy and the pituitary stalk in the rat." *J. Physiol. (Lond.)* **111**: 347-360 (1950).

B54,599/50

In rats, sectioning of the pituitary stalk is followed by regeneration of the hypophyseal portal vessels and fails to cause manifest pituitary deficiency, unless foreign bodies (usually paper plates) are placed between the cut ends of the stalk to prevent the formation of such vascular connections.

Xuereb, G. P., Prichard, M. M. L., Daniel, P. M.: "The hypophyseal portal system of vessels in man." *Q. J. Exp. Physiol.* **39**: 219-230 (1954). C5,988/54

Engelhardt, F.: "Über die Angioarchitektonik der hypophysär-hypothalamischen Systeme" (Angioarchitecture of the hypophyseal-hypothalamic system). *Acta Neuroveg. (Wien)* **13**: 129-170 (1956) (several hundred refs.). C16,881/56

Brettschneider, H.: "Ueber die Innervation der Spezialgefässe des Infundibulum" (The innervation of blood vessels in the infundibulum). *Z. Mikrosk Anat. Forsch.* **62**: 30-39 (1956). C18,499/56

Histologic studies on the nerves of the blood vessels in the infundibulum and stalk of the dog and horse. Claims that the adenohypophysis receives nerve fibers from the hypothalamus have not been confirmed.

Porter, J. C., Jones, J. C.: "Effect of plasma from hypophyseal-portal vessel blood on adrenal ascorbic acid." *Endocrinology* **58**: 62-67 (1956). J11,918/56

Plasma obtained from the hypophyseal-portal veins of hypophysectomized dogs decreased the adrenal ascorbic acid content in cortisol-overdosed, but not in hypophysectomized rats. These observations suggest that blood from the hypophyseal portal vessels contains a substance(s) which accelerates the release of ACTH from the anterior lobe. These observations further suggest that a block in the response of the rat to the stress of unilateral adrenalectomy occurs at some site other than the anterior lobe, perhaps the hypothalamus."

Donovan, B. T., Harris, G. W.: "The effect of pituitary stalk section on light-induced oestrus in the ferret." *J. Physiol. (Lond.)* **131**: 102-114 (1956).

J6,721/56

In the ferret—as in most other species examined—simple section of the pituitary stalk is followed by regeneration of the vessels, as a result of which the initially suppressed, light-induced estrus response reappears. Permanent separation of the hypophysis from the hypothalamus by interposition of waxed paper between the cut ends of the stalk abolishes light-induced estrus and causes a decrease in thyroid and adrenal weight.

Fortier, C., Harris, G. W., McDonald, I. R.: "The effect of pituitary stalk section on the adrenocortical response to stress in the rabbit." *J. Physiol. (Lond.)* **136**: 344-363 (1957). C33,587/57

In rabbits the pituitary stalk was sectioned, and a waxed-paper plate was inserted between the cut ends. This operation, followed "by little or no regeneration of the portal vessels, reduced or abolished the lymphopenic response to restraint and exposure to cold, but exerted little effect on the response to injection of adrenaline or laparotomy or on the adrenal ascorbic acid deple-

tion following unilateral adrenalectomy. These findings support the view that environmental stimuli may be divided into two types: those that affect ACTH secretion solely by an action through the central nervous system, and those that act also by affecting the composition of the blood in the systemic circulation."

Daniel, P. M., Prichard, M. M. L.: "The vascular arrangements of the pituitary gland of the sheep." *Q. J. Exp. Physiol.* **42**: 237-248 (1957). C37,349/57

Koibuchi, E., Fukuda, M.: "Pituitary reaction following the stalk section." *Endocrinol. Jap.* **5**: 11-20 (1958). C54,411/58

Even after transection of the pituitary stalk, burns or laparotomy caused some increase in corticoid secretion, perhaps because "the humoral stimulator could be transported into the anterior pituitary via the systemic circulation."

Duvernoy, A.: "Contribution à l'Étude de la Vascularization de l'Hypophyse" (Contribution to the study of hypophyseal vascularization). Thesis, University of Paris, 1958.

J12,867/58

Doctoral thesis on the structure of the hypothalamus-pituitary vascular connections.

Daniel, P. M., Prichard, M. M. L.: "The effects of pituitary stalk section in the goat." *Am. J. Pathol.* **34**: 433-469 (1958).

C54,157/58

In goats, insertion of a wax plate between the cut ends of the pituitary stalk led to massive infarction of the anterior lobe, but certain areas always survived and underwent regeneration with mitotic proliferation. The posterior lobe became atrophic and showed certain histologic signs of degeneration. The pars intermedia underwent hypertrophy (44 refs.).

Holmes, R. L., Hughes, E. B., Zuckerman, S.: "Section of the pituitary stalk in monkeys." *J. Endocrinol.* **18**: 305-318 (1959). C69,542/59

In rhesus monkeys, pituitary stalk section with interposition of polythene film between the cut ends caused diabetes insipidus and posterior lobe atrophy but no significant adrenal involution.

Clegg, M. T., Ganong, W. F.: "The effect of hypothalamic lesions on ovarian function in the ewe." *Endocrinology* **67**: 179-186 (1960). J12,312/60

In ewes, stereotaxic lesions placed in various parts of the hypothalamus interfered selectively with diverse manifestations of adenohypophyseal activity. In two animals with stalk lesions, peripheral 17-OHCS failed to rise after stress (laparotomy), but in none of the animals was there any significant adenohypophyseal atrophy.

Worthington, W. C. Jr.: "Vascular responses in the pituitary stalk." *Endocrinology* **66**: 19-31 (1960). C79,623/60

Description of the portal blood flow of the pituitary in normal mice and their response to barbiturates, morphine, hemorrhage and burns. Changes in anterior lobe function may depend largely upon variations in blood flow (43 refs.).

Martinez, P. M.: "The Structure of the Pituitary Stalk and the Innervation of the Neurohypophysis in the Cat," p. 158. Thesis, University of Leiden, 1960. G35,942/60

Detailed studies on the vascular supply of the pituitary, with special reference to the portal vessels.

Kovács, K., Dávid, M. A., László, F. A.: "Adrenocortical function in rats after lesion of the pituitary stalk." *J. Endocrinol.* **25**: 9-18 (1962). D32,342/62

In rats in which electrolytic destruction of the pituitary stalk caused diabetes insipidus, the histologic structure of the adrenals was essentially unchanged. Operative stress and uniadrenalectomy elicited no adrenal ascorbic acid depletion, whereas ACTH administration did. The corticosterone content of adrenal venous blood was slightly decreased, but aldosterone secretion remained unchanged. Large doses of corticosterone continued to cause compensatory atrophy.

Adams, J. H., Daniel, P. M., Prichard, M. M. L., Schurr, P. H.: "The volume of the infarct in pars distalis of a human pituitary gland, 30 hr. after transection of the pitu-

itary stalk." *J. Physiol. (Lond.)* **166**: 39-41 (1963). D65,372/63

Adams, J. H., Daniel, P. M., Prichard, M. M. L.: "The effect of stalk section on the volume of the pituitary gland of the sheep." *Acta Endocrinol. (Kbh.)* **43** Supp. 81: 1-27 (1963). E25,464/63

In sheep the pituitary stalk was transected, a plate being inserted between the cut ends to prevent vascular regeneration. Comparatively small areas of the adenohypophysis escaped infarction, and the infundibular process decreased in volume. The location of the infarcted areas is attributed to differential distribution of the stalk vessel.

Adams, J. H., Daniel, P. M., Prichard, M. M. L.: "Volume of the infarct in the anterior lobe of the monkey's pituitary gland shortly after stalk section." *Nature* **198**: 1205-1206 (1963). D69,623/63

In goats, a nonirritant plate was inserted between the cut ends of the pituitary stalk. This caused massive infarcts in the pars distalis with no substantial regeneration. The infundibular process became extremely small, whereas the pars intermedia underwent hypertrophy.

Adams, J. H., Daniel, P. M., Prichard, M. M. L.: "Distribution of hypophysial portal blood in the anterior lobe of the pituitary gland." *Endocrinology* **75**: 120-126 (1964). F15,507/64

Studies in goats, rats and sheep indicate that partial transection of the pituitary stalk causes circumscribed lesions in the adenohypophysis because the portal vessels running down the stalk vascularize specific, limited areas. The neurovascular link between the hypothalamus and pars distalis may include many pathways, each with circumscribed areas of origin and termination. "Thus, individual groups of anterior lobe cells of similar function could receive specific neurohumors produced by particular groups of hypothalamic nerve cells."

F68,589/66

The portal circulation of the pituitary was studied by use of injected preparations and through experiments in which lesions were made in the pituitary stalk to arrest part of the blood flow to the gland. In man, monkeys, sheep and goats, the "pars distalis" derives its sole blood supply from the hypophysial portal vessels, of which there are two main groups. The long portal vessels run down the stalk and supply the greater part of pars distalis (e.g., up to 90% of the lobe in man). The territory supplied by an individual long portal vessel is strictly circumscribed, the cells in a given area of pars distalis being supplied always by the

same portal vessel. The short portal vessels are situated at a lower level than the long ones, and supply a relatively small area along the dorsal border of the lobe. The primary capillary beds which supply these two groups of portal vessels both lie in the neurohypophysis, but at different levels." At their distal end the individual portal vessels are probably distributed to small specific areas of anterior lobe cells comparable to the arrangement at their proximal end. Thus, "an individual portal vessel would convey blood containing neurohumors derived from a specific group of hypothalamic cells to an area of pars distalis which is especially rich in certain types of epithelial cell." The situation in man is illustrated in Figure 14 (p. 1008).

Observations on surgically stressed rats with various interventions in the stalk region. Sham operations failed to affect the maximal rises in corticosterone discharge. "Removal of the pituitary greatly suppressed the secretion of corticosterone. Posterior lobectomy or transection of the portal vessels in the upper stalk had no apparent effect on ACTH release. This finding was interpreted to mean that the posterior pituitary and post-chiasmatic eminence are not obligatory sources of CRF." These and other observations "indicate that CRF comes from the stalk, post-peduncular eminence and/or the cerebrospinal fluid," after entering the portal blood via the post-peduncular and/or pituitary stalk capillaries (42 refs.).

Duvernoy, H.: "The vascular architecture of the median eminence." In: Knigge, K. M.,

Scott, D. E. et al., *Brain-Endocrine Interaction. Median Eminence: Structure and Function*, pp. 79-108. Basel and New York: S Karger, 1972. E10,566/72

Studies on birds and various mammals, including man, showed that the ME "is vascularized by the primary plexus of the hypophysial portal system consisting of a surface network (Mantel-plexus) and a deep network which is made up of the long capillary loops and the subependymal plexus." The primary plexus drains into the adenohypophysis, and certain regions of the ME probably bring blood more or less specifically to some areas of the adenohypophysis. The primary plexus is closely connected with the ventricular cavity, the posterior lobe and the adjacent tuberal vessels.

Spinal Cord

(See also our earlier stress monographs, p. xiii)

Selye, H., MacLean, A.: "Prevention of gastric ulcer formation during the alarm reaction." *Am. J. Dig. Dis.* **11**: 319-322 (1944). A75,010/44

In rats the gastric ulcers produced by transection of the spinal cord at C7 "may be prevented by the prophylactic administration of various food substances, aluminum hydroxide gel and especially by comparatively small doses of dextrose. Dextrose is effective when given either per os or intravenously. It prevents gastric ulcer formation even in doses insufficient to raise the glucose content of the blood above the normal level for the duration of the experiment. The prophylactic effect of dextrose is non-specific in the sense that the compound prevents the formation of gastric ulcers by a variety of widely different damaging agents such as formaldehyde injections, exposure to cold or spinal cord transection."

Andersson, E., Bates, R. W., Hawthorne, E., Haymaker, W., Knowlton, K., Rioch, D. McK., Spence, W. T., Wilson, H.: "The

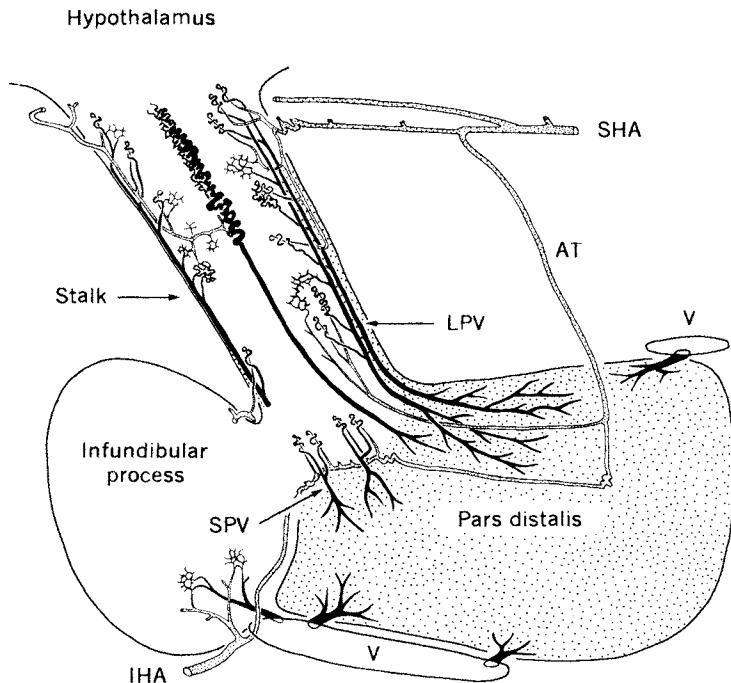

Figure 14. Human pituitary gland, in the sagittal plane, showing the main features of its blood supply. Note in particular the long portal vessels (LPV) and the short portal vessels (SPV) which between them provide the sole blood supply to pars distalis. The artery of the trabecula (AT) runs through pars distalis without supplying the parenchymal cells. In the operation of pituitary stalk section the aim is to transect the stalk just below the arrow to LPV. The median eminence, where the stalk joins the hypothalamus, is ill-defined in man and is not shown here. (Reproduced from *Neuroendocrinology* 1 (1966) by permission of J. H. Adams *et al.* and S. Karger.)

effects of midbrain and spinal cord transection on endocrine and metabolic functions with postulation of a midbrain hypothalamic-pituitary activating system." *Rec. Prog. Horm. Res.* 13: 21-59 (1957). C38,180/57

Egdahl, R. H.: "The differential response of the adrenal cortex and medulla to bacterial endotoxin." *J. Clin. Invest.* 38: 1120-1125 (1959). G33,275/59

In dogs, spinal cord transection at C7 abolishes adrenal medullary discharge by large doses of bacterial endotoxin, but febrile, hypotensive and adrenal cortical responses remain intact. "Epinephrine release is not necessary for the febrile and adrenocortical stimulating effects of endotoxin."

Redgate, E. S.: "Spinal cord and adrenocorticotropic release." *Proc. Soc. Exp. Biol. Med.* 105: 528-531 (1960).

C98,192/60

After spinal cord transection at T₂ in rats,

the adrenal ascorbic acid levels drop, but following recovery, the rats respond to ACTH as do twenty-four-hour hypophysectomized rats, so that ascorbic acid depletion of the adrenals can be employed as an indicator of endogenous ACTH secretion. Intact rats show equivalent ACTH release following electric shock to the fore- or hindpaws, whereas cord-sectioned rats respond only to forepaw stimulation with an ACTH discharge. "The results indicate that intact neural paths in the spinal cord are essential for mediation of ACTH release following hindpaw electrical stimulation."

Redgate, E. S.: "Spinal cord and ACTH release in adrenalectomized rats." *Fed. Proc.* 20: 185 (1961). D3,987/61

Purves, H. D., Sirett, N. E.: "Time course for corticotrophin release from ectopic pituitary grafts." *Endocrinology* 83: 1377-1380 (1968). H5,737/68

In rats a rubber band tightly applied to the hind leg stimulates ACTH release, which is inhibited by spinal cord transection. When five neonatal pituitaries are transplanted under the kidney of hypophysectomized rats, stimulation of ACTH secretion is diminished but not abolished.

Gibbs, F. P.: "Central nervous system lesions that block release of ACTH caused by traumatic stress." *Am. J. Physiol.* **217**: 78-83 (1969). H14,556/69

In rats, spinal cord and medulla oblongata hemisections blocked the increase in plasma corticosterone normally produced by contralateral, but not by ipsilateral, tibial fractures. Radio-frequency lesions placed almost anywhere in the brain stem abolished all fracture-induced ACTH releases within forty-eight hours. When the response was tested after ten days or more, unilateral lesions in the pontine reticular formation blocked the ACTH discharge much more after contralateral than after ipsilateral fractures. The lesions that abolished ACTH release during pentobarbital anesthesia were ineffective in unanesthetized controls. Presumably, "a nervous pathway mediating the traumatic stress-induced release of ACTH ascends to the pons on the side contralateral to the traumatized area." However, since Halász has shown that hypothalamic "deafferentation" does not prevent traumatic stress-induced ACTH secretion, there must be a mechanism other than a direct neural pathway from the pons to the basal hypothalamus.

Makara, G. B., Stark, E., Mihály, K.: "Corticotrophin release induced by traumatic stress in rats with unilateral spinal cord lesion." *Acta Physiol. Acad. Sci. Hung.* **38**: 199-203 (1970). G82,668/70

In rats, hemisection of the cervical spinal cord inhibits the ACTH-releasing effect of contralateral leg fracture, showing that the pathways conveying ACTH releasing information cross the midline.

Allen, J. P., Allen, C. F., Greer, M. A.: "Spinal cord pathways involved in tourniquet stimulation of ACTH secretion." *Neuroendocrinology* **13**: 246-254 (1974). H81,876/74

In adult male pentobarbital-anesthetized rats, a rise in plasma corticosterone twenty minutes after initiation of stress (hind leg tourniquet, bone fractures) indicated ACTH release. "Neither stressor stimulated ACTH

secretion in rats with complete cord transection between L₁ and T₂. Hemisection between L₁ and T₁₀ did not consistently block ACTH secretion following ipsilateral or contralateral tourniquet or leg break, but hemisection above T₁₀ blocked the effect of only the contralateral stressors. Complete cord transection above T₂ was associated with elevated 'basal' plasma immunoreactive ACTH and corticosterone concentrations in unanesthetized rats." These elevations could be partially suppressed by dexamethasone. It is concluded that tourniquet and bone fracture stimulate ACTH secretion through spinal pathways which are not consistently localized between L₁ and T₁₀ but are contralateral to the damaged extremity above T₁₀.

Cosgrove, D. O., Jenkins, J. S.: "The effects of epidural anesthesia on the pituitary-adrenal response to surgery." *Clin. Sci. Molec. Med.* **46**: 403-407 (1974).

J10,530/74

In women undergoing pelvic surgery under epidural anesthesia, cortisol secretion was very low compared to levels in others operated on under general anesthesia. Despite this deficient cortisol discharge, surgery was not impeded. The observations may be interpreted as indicating that "these pathways travel solely, through the spinal cord," and hence are blocked by epidural anesthesia.

Nervous vs. Systemic Stressors

(See also our earlier stress monographs, p. xiii)

Fortier, C.: "Studies on the control of ACTH release by means of hypophyseal transplants." In: Wolstenholme, G. E. W., *Ciba Foundation Colloquia on Endocrinology*, Vol. 4, pp. 124-136. London: J & A Churchill, 1952. B58,855/52

Observations on hypophysectomized rats with intraocular pituitary transplants led to the distinction between systemic (EP, cold, histamine) and neurotropic (sound, immobilization) stressors. The former do, whereas the latter do not, cause eosinopenia after severance of all connections between the hypothalamus and pituitary.

Guillemin, R., Fortier, C.: "Role of histamine in the hypothalamo-hypophyseal re-

sponse to stress." *Trans. N.Y. Acad. Sci.* **15**: 138-140 (1953). C80,534/53

In rats pretreated with Phenergan and exposed to various "neurotropic" (sound, restraint) or "systemic" (cold, histamine) stressors, only histamine became incapable of causing adrenal ascorbic acid discharge. "These results do not support the view that histamine may be an important factor and, in no way, an indispensable link in hypothalamo-pituitary alteration due to neurotropic stress." They also show that histamine cannot be the only humoral agent responsible for pituitary stimulation during stress.

Harris, G. W.: "The reciprocal relationship between the thyroid and adrenocortical responses to stress." In: Wolstenholme, G. E. W. and Cameron, M. P., *Ciba Foundation Colloquia on Endocrinology*, Vol. 8, pp. 531-550. London: J & A Churchill, 1955.

C3,662/55

In rabbits, transection of the pituitary stalk, with steps taken to prevent vascular regeneration, decreases the activity of the thyroid, adrenal cortex and ovaries; it also markedly reduces the effect of nervous and emotional stressors on the thyroid and adrenal cortex. On the other hand, the same intervention has little influence upon adrenocortical and thyroid responses to surgical trauma or large doses of EP. These findings are interpreted as evidence supporting the view that neurogenic and "systemic" stressors affect the pituitary through distinct mechanisms.

Mialhe-Voloss, C.: "Importance relative de l'antéhypophyse et de la posthypophyse dans les agressions systémiques et neurotropes" (Relative importance of anterior and posterior pituitary lobe in systemic and neurotropic stress). *Ann. Endocrinol.* (Paris) **17**: 104-110 (1956). C18,994/56

Fortier, C., Harris, G. W., McDonald, I. R.: "The effect of pituitary stalk section on the adrenocortical response to stress in the rabbit." *J. Physiol.* (Lond.) **136**: 344-363 (1957). C33,587/57

In rabbits the pituitary stalk was sectioned, and a waxed-paper plate was inserted between the cut ends. This operation, followed "by little or no regeneration of the portal vessels, reduced or abolished the lymphopenic response to restraint and exposure to cold, but exerted little effect on the response to injection of adrenaline or laparotomy or on the adrenal ascorbic acid deple-

tion following unilateral adrenalectomy. These findings support the view that environmental stimuli may be divided into two types: those that affect ACTH secretion solely by an action through the central nervous system, and those that act also by affecting the composition of the blood in the systemic circulation."

Nowell, N. W.: "Studies in the activation and inhibition of adrenocorticotropic secretion." *Endocrinology* **64**: 191-201 (1959).

C63,783/59

In neurohypophysectomized rats, adrenal ascorbic acid depletion could be produced by cold, hypertonic saline, and bell-ringing. A distinction is made between ascorbic acid factor (AAF) and adrenal weight factor (AWF) as two variants of ACTH. The neurohypophysis participates in the release of AAF, which is regulated by separate nerve centers in the hypothalamus. Enucleated adrenals regenerate under the influence of AWF, which is believed not to depend upon hypothalamic centers. "The neurohypophysis is involved in the release of ACTH/AAF in response to systemic stresses but not to emotional ones."

Smelik, P. G.: "The role of the posterior lobe of the pituitary gland in the corticotrophic response to acute stress." *Acta Physiol. Pharmacol. Neerl.* **9**: 125-126 (1960).

C89,917/60

In neurohypophysectomized rats, certain types of stressors no longer produce adrenal ascorbic acid discharge. It is suggested that "emotional stimuli activate the adrenal cortex only in the presence of the posterior lobe, but that somatic stimuli act as normally when the posterior lobe has been removed."

Giuliani, G., Martini, L., Pecile, A.: "Midbrain section and release of ACTH following stress." *Acta Endocrinol.* (Kbh.) Supp. 51: 37 (1960).

C93,249/60

In hypophysectomized rats with pituitary grafts in the anterior chamber of the eye, most stressors (ether anesthesia, anoxia, abdominal surgery, EP, acetylcholine, histamine, formalin, insulin, salicylate) and even unilateral adrenalectomy, failed to increase ACTH release (adrenal ascorbic acid tests), whereas vasopressin and hypertonic sodium chloride solutions remained highly effective. The same was true after cortisol treatment or midbrain section, although in the latter case not only vasopressin and hypertonic sodium chloride but also formalin, insulin,

salicylate and histamine retained their activity. Apparently, the pathways of mediation differ for the various stressors, but among the agents tested, only vasopressin acts directly upon the anterior lobe. [The brief abstract of an oral communication does not lend itself to evaluation (H.S.).]

Wied, D. de: "The significance of the antidiuretic hormone in the release mechanism of corticotropin." *Endocrinology* **68**: 956-970 (1961). D7,440/61

In rats, posterior lobe extirpation greatly reduces the antidiuretic response to hemorrhage, histamine or painful stimuli. Exposure of these animals to "systemic stress" (hemorrhage, histamine, nicotine) causes increases in plasma free corticosterone as great as those in sham-operated controls. However, "neurogenic stressors" (strange environment, sound, pain) become significantly less effective, although the adrenal is enlarged after posterior lobectomy. These and other observations led the authors to the conclusion that "the antidiuretic hormone is involved in the corticotrophic effect of neurogenic stimuli."

Matsuda, K., Duyck, C., Kendall, J. W. Jr., Greer, M. A.: "Pathways by which traumatic stress and ether induce increased ACTH release in the rat." *Endocrinology* **74**: 981-985 (1964). F12,792/64

In rats, removal of all forebrain anterior to the superior colliculus, leaving an isolated ME, stalk, and pituitary intact, still permits ACTH release (corticosterone in adrenal effluent) in response to ether anesthesia with or without additional traumatic stress (fracture of foreleg). However, after Nembutal anesthesia, traumatic stress is no longer active in this respect. Bone fracture distal to a section of the spinal cord in otherwise intact rats also fails to raise adrenocortical secretion under Nembutal but not under ether anesthesia. "Ether apparently directly stimulates the median eminence to cause increased ACTH release. Traumatic stress induces ACTH release through ascending neural pathways feeding to the hypothalamus through the dorsal mesencephalon."

Zarrow, M. X., Denenberg, V. H., Haltmeyer, G. C., Brumaghin, J. T.: "Plasma and adrenal corticosterone levels following exposure of the two-day-old rat to various stressors." *Proc. Soc. Exp. Biol. Med.* **125**: 113-116 (1967). F80,161/67

Even in two-day-old rats of both sexes,

ACTH, histamine, electroshock, heat and cold increased the plasma and adrenal corticosterone levels. Only tight ligature above the knee joint was ineffective in this age group, perhaps because (as Fortier suggested) neural stressors (pain) act through a different pathway. Presumably, the pituitary-adrenal axis is operative in the two-day-old rat, but "the neural component in the system is not active as yet." Contradictions in the earlier literature on the responsiveness of the neonatal pituitary are analyzed.

Feldman, S., Conforti, N., Chowers, I., Davidson, J. M.: "Differential effects of hypothalamic deafferentation on responses to different stresses." *Isr. J. Med. Sci.* **4**: 908-910 (1968). H3,150/68

Following deafferentation of the hypothalamus (Halász knife), both the normal concentration of plasma corticosterone of rats and its considerable increase after "ether stress" are unchanged. On the other hand, "audiogenic stress" appears to cause no such evidence of ACTH discharge. "It might be possible to subdivide ACTH-releasing stimuli into 'systemic' or 'neurogenic' on the basis of whether or not they can activate the hypothalamo-pituitary unit in the absence of afferent nervous input to this area."

Stark, E., Fachet, J., Makara, G. B., Mihály, K.: "An attempt to explain differences in the hypophyseal-adrenocortical response to repeated stressful stimuli by their dependence on differences in pathways." *Acta Med. Acad. Sci. Hung.* **25**: 251-260 (1968). G63,921/68

In rats, "certain non-specific stimuli that raise the plasma corticosterone level when administered on a single occasion fail to raise it when administered repeatedly whereas others raise it independently of the number of administrations. It is suggested that stressor agents reach the CRF-secreting hypothalamic cells by different pathways, and that the CRF-activating mechanism of some stressors does adapt itself to repeated stimuli, that of others does not."

Lutz, B., Koch, B., Mialhe, C.: "Libération des hormones antidiurétique et corticotrope au cours de différents types d'agression chez le rat" (Release of antidiuretic and corticotrophic hormones during different types of stress in rats). *Horm. Metab. Res.* **1**: 213-217 (1969). H18,220/69

In rats a neurotropic stressor (sound) causes a simultaneous discharge of ACTH

and vasopressin, whereas systemic stressors (ether, histamine) result in a release of vasopressin followed by that of ACTH.

Stark, E.: "Regulation of ACTH secretion in stressful conditions. The nature of afferent pathways involved in stress-induced ACTH secretion." *Acta Med. Acad. Sci. Hung.* **29**: 77-88 (1972). J10,355/72

A review of the literature and personal observations indicate that in rats, certain stressors stimulate CRF-ACTH release via neurons in the medial basal hypothalamus, whereas others act even after destruction of these neurons. "Enhanced ACTH release induced by endotoxin can be observed in animals deprived of the hypothalamus, even if the hypophyseal stalk has been transected weeks earlier. In this case the neurohypophysis does not come into consideration as a source of CRF or ACTH" (36 refs.).

Briaud, B.: "Réponse corticosurrénalienne aux agressions neurotropes et systémiques après injection de corticostéroïdes" (Adrenocortical response to neurotropic and systemic stress after corticosteroid injection). *J. Physiol. (Paris)* **66**: 259-270 (1973).

J7,439/73

In rats, about twice as much corticosterone or dexamethasone is needed to inhibit the adrenal response to systemic (ether) than to neurogenic (sound) stress of equal intensity.

Collu, R., Jéquier, J. C., Letarte, J., Leboeuf, F., Ducharme, J. R.: "Effect of stress and hypothalamic deafferentation on the secretion of growth hormone in the rat." *Neuroendocrinology* **11**: 183-190 (1973).

H68,127/73

Ether and auditory stressors were equally effective in diminishing plasma STH (radioimmunoassay) in controls and in frontally deafferented rats. Ether also inhibited STH secretion in completely deafferented animals, whereas auditory stress was ineffective. α -MT pretreatment blocked the effect of ether after complete deafferentation. These and other data "seem to indicate that ether stress is transmitted through a humoral, dopaminergic pathway, while auditory stress follows a nervous pathway." [The many observations suggesting increased STH secretion during stress are not discussed (H.S.).]

Allen, J. P., Allen, C. F.: "Role of the

amygdaloid complexes in the stress-induced release of ACTH in the rat." *Neuroendocrinology* **15**: 220-230 (1974). H91,996/74

Plasma corticosterone determinations in the rat "suggest that the amygdalae facilitate rather than directly transmit neurogenic stress-induced signals (leg break) but not signals from systemic stresses (ether)." However, "bilateral paired amygdaloid lesions blocked the effect of the leg break but not of ether or tourniquet. Bilateral paired lesions between the lateral hypothalamic area and the amygdalae also blocked the effect of the leg break but not ether or tourniquet, whereas bilateral lesions in the anterior portion of the striae terminali did not block the leg-break effect."

Stark, E., Makara, G. B., Marton, J., Palkovits, M.: "ACTH release in rats after removal of the medial hypothalamus." *Neuroendocrinology* **13**: 224-233 (1974).

H81,874/74

In rats, after ablation of the medial hypothalamus, "*E. Coli* endotoxin or a large dose of formaldehyde induced a significant increase in ACTH release, whereas either sham-adrenalectomy under ether anesthesia or a small dose of formaldehyde did not." Both resting and stress-induced discharges of ACTH could be inhibited by dexamethasone, even in the absence of the medial hypothalamus. Presumably pathways through which endotoxin and formaldehyde can release ACTH may bypass the hypothalamus, and the feedback action of the glucocorticoid is effective outside the hypothalamus.

Allen, J. P., Allen, C. F.: "The effect of dimethyl sulfoxide on hypothalamic pituitary-adrenal functions in the rat." *Ann. N.Y. Acad. Sci.* **243**: 325-336 (1975).

H98,565/75

Experimental observations suggesting that dimethyl sulfoxide (DMSO) acts either directly on the hypothalamic-anterior pituitary complex to cause secretion of ACTH (presumably through the release of CRF) or that it potentiates the effect of circulating ACTH on the adrenal cortex to stimulate the secretion of corticosterone. DMSO is ineffective whereas it significantly raises plasma corticosterone in adrenalectomized or deafferented animals.

HORMONAL MECHANISMS

All the mechanisms that regulate the responses of the body during stress are so closely interrelated and interdependent that here—as in virtually all other sections of this book—it is highly artificial and arbitrary to subdivide observations into separate categories. However, no other procedure is possible if this book is to be a practically useful source of information in which key references are presented in an easily retrievable manner. Hence, at least the majority of the most pertinent data concerning any one subject are listed under a particular heading, preferably that most closely related to the subject of the publication. Obviously, it would lead to an enormously wasteful number of repetitions if every publication were discussed under each heading upon which it might have some bearing. Thus, for example, the neurohormonal and the hormonal mechanisms of corticoid discharge following application of a painful stimulus to a leg could have been mentioned at each point of the nervous system through which the evocative stimulus travels (from the peripheral nerves to the hypothalamus), and then again under CRF and the portal vessels of the hypothalamohypophyseal system, under hormonal mechanisms in relation to the adenohypophysis and the adrenal cortex, or even the various ACTH- and corticoid-feedback mechanisms that modulate such a response. Indeed, even this classification would not be exhaustive.

I felt that the arbitrariness in my classification should be admitted and explained clearly at the outset, but I will not repeat it although it is applicable to each subheading in the following sections.

A general outline of my classification will help the reader determine what sections he should consult to find data of special interest in connection with his problem, as long as he realizes that all data pertinent to it will rarely, if ever, be listed under any one caption.

As a guide for such searches of the literature, it is useful to enumerate here the subheadings used, be they separate anatomic structures, individual hormones or special regulating mechanisms:

Anterior Lobe of the Hypophysis

Hypophysectomy

Anterior Lobe Transplantation

ACTH

ACTH Feedback

Extra-adrenal Actions of ACTH

Not Glucocorticoid-like Actions of ACTH

Not Stress-like Actions of ACTH

Somatotrophic Hormone (STH, GH)

Somatostatin, Somatomedin, Somantin

Thyrotrophic Hormone (TTH, TSH)

Luteotropic Hormone (LTH, Prolactin)

Middle (Intermediate) Lobe of the Hypophysis

Melanotropic Hormone (MTH, MSH)

Posterior (Neural) Lobe of the Hypophysis

Vasopressin, Antidiuretic Hormone (ADH), Oxytocin

Adrenals

Epinephrine, Norepinephrine (EP, NEP)

Dopamine

Much additional evidence concerning the participation of hormones in stress reactions will be found in Chapter III, Characteristic Manifestations of Stress, in the subsection devoted to Hormones and Hormone-like Substances. In fact, it is somewhat arbitrary whether the observation of a change in the metabolism of a hormone is merely described as a characteristic of the stress reaction, or as a fact that illustrates its participation in the mechanism of stress responses.

ANTERIOR LOBE OF THE HYPOPHYSIS

The anterior lobe, or adenohypophysis, acting under the influence of hypothalamic neurohormones, plays a central role in the regulation of hormonal adaptation to non-specific demands. The most important activity of the anterior pituitary during stress is the secretion of ACTH, which stimulates corticoid production. This response is controlled mainly through two negative biofeedback mechanisms: both ACTH itself and the corticoids secreted under its influence act back upon the adenohypophysis, and tend to diminish excessive secretion of ACTH.

It is noteworthy that ACTH also has direct extra-adrenal actions and effects, which are not duplicated either by glucocorticoids or by exposure to stress. The literature supporting these views will be presented in separate sections entitled, Extra-adrenal Actions of ACTH, Not Glucocorticoid-like Actions of ACTH, and Not Stress-like Actions of ACTH.

In addition, there is strong evidence that stress is associated with characteristic changes in the secretion of STH (probably related to somatostatin, somatomedin and somantin), TTH and LTH. Stress is also manifested by variations in the production of other gonadotropic hormones, particularly FSH and LH (See Chapter III, Characteristic Manifestations of Stress). There is no convincing reason to believe that these are of special importance for defense against acute stressors, although they undoubtedly modify the development of sex organs and sexual behavior during chronic stress.

The role of the pituitary in the G.A.S. was the first major subject of investigation immediately after the discovery of this syndrome. The most useful techniques proved to be: (1) Hypophysectomy (which showed that, in the absence of the anterior lobe, stressors can no longer increase corticoid production). (2) Anterior lobe transplantation in ortho- or heterotopic positions (which showed that unless contact with the ME and reestablishment of the portal circulation are possible, the adenohypophyseal tissue responds to stressors with little if any ACTH discharge). (3) Injection of increasingly purified anterior pituitary hormones into intact or hypophysectomized animals (which helped to identify the role played by each of these substances during stress).

By the use of ^{86}Rb it has been possible to measure blood flow through various organs in the rat. It was noted that under the influence of "ether stress" the blood flow increased within a few minutes in the adenohypophysis and even more in the thyroid. Adrenalectomy did not affect the stress-induced rise in blood flow in the pituitary but blocked it in the thyroid. Curiously, the blood flow in the ME remained unchanged under all these experimental conditions.

Hypophysectomy

One of the first stress-related experiments, performed in 1936 immediately after the discovery of the stress syndrome, was designed to establish whether any characteristic manifestations of the G.A.S. would be abolished by hypophysectomy. It was found that in the rat, adrenocortical enlargement with acute loss of lipids and thymicolympathic atrophy produced by a variety of stressors (surgical trauma, cold, restraint, fasting, atropine, morphine, formaldehyde, EP) were invariably blocked after ablation of the pituitary. However, the thymus involution was more completely abolished by adrenalectomy than by hypophysectomy. Curiously, the lymphopenia produced by stressors (for example, EP) is also more completely abolished by adrenalectomy than by hypophysectomy. These findings suggested that the adrenal cortex may not be exclusively under pituitary control, but the mechanism of this extrahypophyseal action has not yet been fully clarified. Since hypophysectomized animals also proved to be extraordinarily susceptible to the lethal effects of stressors, it was concluded that adrenal stimulation and other manifestations of the alarm reaction "enable the organism to meet critical situations more efficiently."

One clue concerning the possible mechanism of an extrahypophyseal corticoid release was found in the observation that hypothalamic stimulation increases adrenal blood flow and arterial pressure, and after hypophysectomy there is a positive correlation between corticoid release and stimulation of blood flow. Presumably, adrenal blood flow is one of the factors of extrahypophyseal corticoid mobilization.

Hypophysectomy

(See also our earlier stress monographs, p. xiii)

Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* **17**: 234-248 (1936). 36,032/36

First detailed description of the "alarm reaction," characterized by adrenocortical enlargement with acute loss of lipids, thymicolympathic atrophy, and loss of body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for forty-eight hours or more, large doses of atropine, morphine, formaldehyde or EP). Adrenalectomy and, to a lesser extent, hypophysectomy prevent the thymus involution. "The changes caused by a drug when it is given for the first time will subside later in spite of the continued administration of this drug" but greatly shorten survival. Perhaps the adrenal enlargement, loss of body weight and the other manifestations of the alarm reaction "enable the organism to meet critical situations more efficiently."

Selye, H.: "Studies on adaptation." *Endocrinology* **21**: 169-188 (1937).

38,798/37

Hypophysectomy lessens the accidental involution of the thymus and adrenalectomy inhibits it completely, but both these operations greatly diminish resistance to all stressors examined. Thyroidectomy and ovariectomy do not considerably interfere with the thymicolympathic involution and splenic atrophy characteristic of the formalin-induced alarm reaction, nor do they significantly increase mortality.

G82,669/70

In rats, hypothalamic stimulation increased adrenal blood flow and arterial pressure. There was no correlation of corticoid release and blood flow upon stimulation before hypophysectomy, while after hypophysectomy, a positive correlation of the responses was noted, with an increase in corticoid discharge. "It is concluded that adrenal blood flow is one of the factors of extra-hypophyseal corticoid mobilization. Their coordination is probably organized at the hypothalamic level." To explain corticoid release after hypophysectomy, mobilization of extrahypophyseal ACTH depots may also be considered, but this would not be detectable in the presence of the pituitary with its much more effective power of ACTH discharge.

Camarda, R., D'Alessandro, F., Guarneri, R., Bonavita, V.: "Stress and brain nicotinamide adenine dinucleotides in normal and hypophysectomized rats." *Acta Neurol. (Napoli)* 26: 501–510 (1971).

J20,829/71

In rats, restraint or injection of saline modifies NAD, NADH, NADP and NADPH levels in the brain. Hypophysectomy prevents these changes.

Anterior Lobe Transplantation

It was shown as early as 1941 that adenohypophyseal transplants in the sella, unlike those placed in the anterior chamber of the eye, stimulated adrenal growth in the hypophysectomized rat. In 1949, it was shown furthermore that homotransplantation of anterior pituitary tissue in the anterior chamber of the eye still permitted the discharge of adrenal ascorbic acid in hypophysectomized rats exposed to surgical trauma or cold. It was concluded that at least certain stressors can stimulate ACTH release through pathways other than direct connections between the pituitary and hypothalamus.

Similar findings were reported for hypophysectomized rats bearing intraocular or intrasplenic adenohypophyseal grafts following treatment with histamine, while sound and immobilization failed to elicit ACTH discharge when the hypothalamus-hypophyseal pathways were interrupted.

Subsequently, the classic experiments of G. W. Harris (1952) showed that in rats adenohypophyseal homografts placed under the ME maintain estrus, pregnancy, lactation, as well as a normal ovarian, adrenal and thyroid structure. Similar grafts located under the temporal lobe had no such effects. It was concluded that presumably "the secretion of anterior pituitary hormones is under hypothalamic control, mediated by the hypophysial portal vessels." These and other observations led Fortier (1952) to distinguish between systemic (EP, cold, histamine) and neurotropic (sound, immobilization) stressors, only the former being capable of producing ACTH discharge after severance of all connections between the hypothalamus and the pituitary.

Vasopressin failed to cause ACTH release in hypophysectomized rats unless they carried ocular adenohypophyseal homotransplants. These observations were considered to be "consistent with the hypothesis that the posterior pituitary hormones act as humoral transmitting agents which, released by the hypothalamus into the hypophysial portal system, can activate the anterior pituitary to discharge ACTH." According to these observations, even heterotopic adenohypophyseal grafts can be activated by vasopressin.

In rats with homologous adenohypophyseal grafts in the anterior chamber of the eye, ACTH secretion also occurred after unilateral adrenalectomy.

Fetal pituitaries implanted into the eye of hypophysectomized rats remained viable and developed highly differentiated chromophobes but only few sparsely granulated acidophils and beta cells. These glands were also capable of a moderate ACTH discharge during acute stress.

In another series of hypophysectomized rats with pituitary grafts in the anterior chamber of the eye, acetylcholine, histamine, 5-HT, oxytocin and EP failed to cause ACTH release, whereas vasopressin was active when directly applied to the grafts. In glucocorticoid-blocked rats, vasopressin and oxytocin also elicited an ACTH discharge when given intravenously. It was postulated that perhaps posterior pituitary principles could act as physiologic regulators of ACTH output.

In hypophysectomized weanling rats bearing four pituitary transplants under the kidney capsule, somatic growth continued although at a slow rate, and the thyroids and gonads were partially maintained. Presumably, "in rats, somatotropin production and release are not completely dependent upon an intact hypothalamic-pituitary system." However, in other experiments on hypophysectomized rats with pituitary grafts in the eye, STH and gonadotropic activity ceased, but some ACTH and TTH secretion continued despite severance of all connections with the ME.

Amphenone causes adrenal enlargement in rats with adenohypophyseal grafts under the kidney capsule. This drug stimulates the adrenal by suppressing corticoid production; hence, the grafts apparently maintain their sensitivity to the corticoid feedback mechanism.

In thirty-day-old rats with adenohypophyseal transplants in the ventral hypothalamus, the normal structure of the anterior lobe was maintained, but grafts in other sites became undifferentiated.

In another series of hypophysectomized rats with pituitary homotransplants under the kidney capsule, ether, histamine and unilateral adrenalectomy failed to cause

ACTH discharge, although the grafts contained approximately normal amounts of ACTH. Presumably, it is the release of ACTH that depends upon direct contact with the hypothalamus. The adrenals were slightly heavier in transplant-bearing rats, possibly owing to a factor (other than ACTH) secreted by the graft.

In hypophysectomized rats with pituitary autotransplants under the kidney capsule, chronic CRF treatment maintained the synthesis of ACTH and permitted the graft to release ACTH when acutely stimulated by CRF. No such effect was obtained with vasopressin or α -MTH.

In the absence of stress, heterotopic pituitary homotransplants failed to support ACTH secretion at a level significantly above that in hypophysectomized controls. Yet in rats with intraocular homografts of adenohypophysis, the transplants retain their normal EM structure.

On the other hand, the MTH activity of heterotopic pituitary homotransplants drops considerably in hypophysectomized weanling rats, although the ACTH content remains normal.

In hypophysectomized rats with adenohypophyseal grafts in contact with the ME, thyroid and adrenal structure was well maintained, and even compensatory hypertrophy following uniadrenalectomy and goiter after methylthiouracil treatment were evident. Contact with the ME was not necessary for preservation of gonadotropic hormone secretion.

In young hypophysectomized rats with pituitary autografts in the kidney, continuous infusion of bovine ME extracts through the renal artery caused enlargement of the adrenals, thyroids and ovaries. These findings are taken as "direct evidence that the hypothalamic neurohumors act not only as 'releasing' factors but also have trophic effects on many other phases of adenohypophyseal functions."

Pituitary autografts under the kidney rapidly dedifferentiated and lost their function in rats, but resumed their normal structure as well as their adrenotropic and thyrotropic effect upon continuous infusion of ovine ME extracts. This again shows that the latter are not only releasing factors but also have trophic effects.

Hypophysectomized rats with transplants (under the renal capsule) of ten pituitaries from very young donors maintained nearly normal adrenal weights and plasma corticosterone levels. The grafts showed histologic evidence of anterior and intermediate lobe tissue growth. Dexamethasone suppressed corticosterone secretion in these animals, indicating that contiguity of the adenohypophysis with the ME is not necessary for corticoid feedback activity.

LTH secretion and lactation increase in rats after pituitary stalk transection as well as following hypophysectomy with heterotopic pituitary transplants.

In hypophysectomized adult rats bearing five neonatal pituitaries under the kidney capsule, adrenal weight and plasma corticosterone levels were not significantly different from those after hypophysectomy alone, but one hour following severe stress (for example, thiouracil, hemorrhage, restraint) significant elevations of plasma corticosterone occurred. The response to hemorrhage was inhibited by dexamethasone in graft-bearing rats, and lysine vasopressin released ACTH but only at very high dose levels. Apparently, such heterotopic grafts can store ACTH, and even release it, but only under the influence of very strong stimuli; furthermore, the corticoid feedback mechanism does not require the integrity of hypothalamus-hypophyseal connections.

Transplantation of ACTH-producing pituitary tumors decreased the weight and ACTH content of the pituitary in rats. Plasma ACTH rose slowly despite a considerable reduction in pituitary ACTH. At this time, stress still increased plasma ACTH,

but did not do so after hypophysectomy. Tumor implantation before adrenalectomy prevented the usual rise in plasma ACTH, possibly through the "short loop feedback" effect of ACTH from the tumor.

In rats with multiple adenohypophyseal homografts in the kidneys, plasma corticosterone levels rose after removal of the cerebral cortex. This effect was diminished by subsequent extirpation of the entire forebrain, as long as hypothalamic islands remained intact. Stalk and ME injections into graft-bearing hypophysectomized rats raised the plasma corticosterone levels, presumably because a neurohumor of hypothalamic origin passed into the general circulation.

Perhaps the most important facts learned from experiments with adenohypophyseal grafts are that they maintain their structure best, and are most effective in secreting ACTH, if placed in direct contact with the ME so that vascular connections with the latter may be reestablished. Heterotopic adenohypophyseal grafts are much less effective, but if they are numerous, and especially if they are derived from neonatal rats, they do take and can secrete ACTH under the influence of severe stressors. Such heterotopic grafts are also sensitive to corticoid feedback, since their ACTH-secreting power is inhibited by dexamethasone. Removal of the forebrain, excepting a hypothalamic island, increases plasma corticosterone in graft-bearing hypophysectomized rats. These also respond normally with ACTH release to stalk or ME extract injections.

Anterior Lobe Transplantation

(See also our earlier stress monographs, p. xiii)

Cutuly, E.: "Autoplastic grafting of the anterior pituitary in male rats." *Anat. Rec.* **80** Supp. 1: 83-97 (1941). A36,421/41

Autoplastic adenohypophyseal transplants were made in rats, either in the anterior chamber of the eye or in the sella. "Only sellar grafts were adrenotropic, and neither ocular nor sellar grafts caused any detectable activation of the thyroid gland." Earlier literature on pituitary transplants is reviewed (21 refs.).

Fortier, C., Selye, H.: "Adrenocorticotrophic effect of stress after severance of the hypothalamo-hypophyseal pathways." *Am. J. Physiol.* **159**: 433-439 (1949).

B37,371/49

In rats the hypothalamus-hypophyseal connections were severed in one experiment by partial hypophysectomy, and in another through anterior lobe homotransplantation into the anterior chamber of the eye following hypophysectomy. After these interventions, surgical trauma and cold still produced significant adrenal ascorbic acid discharge. Presumably, ACTH release by these stres-

sors is not exclusively mediated through nervous pathways.

Cheng, C.-P., Sayers, G., Goodman, L. S., Swinyard, C. A.: "Discharge of adrenocorticotrophic hormone from transplanted pituitary tissue." *Am. J. Physiol.* **159**: 426-432 (1949). B45,616/49

In hypophysectomized rats, intraocular and intrasplenic grafts of adenohypophyseal tissue promptly discharge ACTH in response to "histamine stress," but the amount of hormone release is subnormal. "The results have been interpreted to mean that neural or vascular connections between the hypothalamus and the anterior pituitary are not essential for the immediate discharge of ACTH in acute stress."

Schweizer, M., Long, M. E.: "The effect of intra-ocular grafts of anterior pituitary on the thyroid gland of hypophysectomized guinea pigs." *Endocrinology* **47**: 454-457 (1950). B53,919/50

A limited number of hypophysectomized animals with intraocular adenohypophyseal grafts showed partial maintenance of the adrenal cortex and very slight thyrotropic activity.

Schweizer, M., Long, M. E.: "Partial maintenance of the adrenal cortex by an-

terior pituitary grafts in fed and starved guinea pigs." *Endocrinology* **46**: 191-206 (1950). B47,455/50

In hypophysectomized guinea pigs, intraocular homografts of the adenohypophysis partially maintained the structure of the adrenal glands.

Fortier, C.: "Dual control of adrenocorticotrophic release." *Endocrinology* **49**: 782-788 (1951). B61,227/51

Following homotransplantation of the anterior pituitary into the anterior chamber of the eye, EP, cold and histamine still caused definite eosinopenia, while sound and immobilization failed to do so. "These results suggest a dual regulation of ACTH release, one purely humoral, in response to systemic stimuli, the other probably neuro-humoral, mediated by the hypothalamo-hypophysial neurovascular pathways, and coming into play under the influence of nervous and emotional stimuli."

Harris, G. W., Jacobsohn, D.: "Functional grafts of the anterior pituitary gland." *Proc. R. Soc. Lond. [Biol.]* **139**: 263-276 (1952).

B82,095/52

In hypophysectomized adult rats with adenohypophyseal homografts from a closely related species placed under the ME, pituitary functions were well maintained as indicated by estrus, pregnancy, lactation, and ovarian, adrenal and thyroid structure. Grafts under the temporal lobe had no such effects, because they did not establish vascular connections with the portal circulation of the ME. Grafts from immature donors in adult recipients showed hastened development. "These results offer strong support to the view that the secretion of anterior pituitary hormones is under hypothalamic control, mediated by the hypophysial portal vessels."

Harris, G. W., Jacobsohn, D.: "Functional hypophyseal grafts." In: Wolstenholme, G. E. W., *Ciba Foundation Colloquia on Endocrinology*, Vol. 4, pp. 115-119. London: J & A Churchill, 1952. B76,071/52

In hypophysectomized rats, hypophyseal homotransplants under the temporal lobe of the brain or the anterior chamber of the eye show good vascularization but do not maintain adrenal trophic function. Similar transplants under the ME are very effective in this respect because they form vascular connections with the hypophysial portal system.

Fortier, C.: "Studies on the control of ACTH release by means of hypophyseal

transplants." In: Wolstenholme, G. E. W., *Ciba Foundation Colloquia on Endocrinology*, Vol. 4, pp. 124-136. London: J & A Churchill, 1952. B58,855/52

Observations on hypophysectomized rats with intraocular pituitary transplants led to the distinction between systemic (EP, cold, histamine) and neurotropic (sound, immobilization) stressors. The former do, whereas the latter do not, cause eosinopenia after severance of all connections between the hypothalamus and the pituitary.

Martini, L., Poli, A. de: "Neurohumoral control of the release of adrenocorticotrophic hormone." *J. Endocrinol.* **13**: 229-234 (1956). C15,162/56

In hypophysectomized rats, injection of posterior pituitary hormones failed to cause the usual eosinopenia and adrenal ascorbic acid depletion. However, hypophysectomized rats with ocular adenohypophyseal homotransplants from adult rats responded to both intraperitoneal and intraocular injections of posterior pituitary hormones with eosinopenia and adrenal ascorbic acid depletion. "These results are consistent with the hypothesis that the posterior pituitary hormones act as humoral transmitting agents which, released by the hypothalamus into the hypophysial portal system, can activate the anterior pituitary to discharge ACTH."

Siperstein, E. R., Greer, M. A.: "Observations on the morphology and histochemistry of the mouse pituitary implanted in the anterior eye chamber." *J. Natl. Cancer Inst.* **17**: 569-599 (1956) (35 refs.).

J12,751/56

Fry, E. G., Long, C. N. H.: "The function of ocular and kidney transplants of pituitary tissue in the hypophysectomized rat." *20th Int. Congr. Physiol.*, pp. 307-308. Brussels, 1956.

C23,385/56

In rats, homologous anterior pituitary transplants in the anterior chamber of the eye took, whether the donors were infantile or adult. The gonads, thyroids and adrenals were maintained, and under the "stress of unilateral adrenalectomy," ACTH secretion occurred, as indicated by adrenal ascorbic acid depletion. Transplants under the renal capsule appeared to be less effective, yet they supported growth and reproduction after hypophysectomy. [This brief abstract gives no details and is difficult to evaluate (H.S.).]

grafts in the hypophysectomized male rat." *Endocrinology* **61**: 742-752 (1957).

C44,867/57

Fetal pituitaries implanted in the anterior chamber of the eye of hypophysectomized rats remain viable and develop into highly differentiated adenohypophyseal tissue, which consists mainly of chromophobes but also contains sparsely granulated acidophils and β -cells. The somatic growth of implant-bearing hypophysectomized rats is slightly above that of controls. "Evidence of slight secretion of ACTH by the implants was obtained from studies of adrenal weight and depletion of adrenal cholesterol following acute stress."

J12,364/58

In rats, pituitaries autografted on the kidney lose the power to maintain ovaries, adrenals and thyroids, but when retransplanted under the ME, they regain their ability to maintain these glands. This is true with respect to the secretion of ACTH, TTH, FSH and LH.

Timmer, R. F., Sanders, A. E., Rennels, E. G.: "Evidence for limited ACTH secretion by pituitary autografts in the renal capsule of the rat." *Tex. Rep. Biol. Med.* **17**: 632-636 (1959).

D97,005/59

J10,796/59

In hypophysectomized rats with pituitary grafts in the anterior chamber of the eye, acetylcholine, histamine, 5-HT, oxytocin and EP failed to elicit an ACTH discharge (ascorbic acid depletion test), whereas vasopressin was active when applied directly to the grafted pituitary. In glucocorticoid-blocked rats, vasopressin, oxytocin and lysine-vasopressin caused ACTH release when given intravenously. It is noteworthy that in intact rats, EP, NEP, acetylcholine, histamine, 5-HT, vasopressin, oxytocin, lysine-vasopressin and synthetic oxytocin are all effective in this respect. Possibly, "posterior pituitary principles could play a role in the physiological regulation of ACTH output."

Hertz, R.: "Growth in the hypophysectomized rat sustained by pituitary grafts." *Endocrinology* **65**: 926-931 (1959).

C78,359/59

Hypophysectomized weanling rats bearing four pituitary transplants under the kidney capsule continue to grow at about two-thirds the normal rate, and their thyroids and gonads are also partially maintained. "It is concluded that, in the rat, somatotropin production and release are not completely dependent upon an intact hypothalamic-pituitary system."

Martini, L., Poli, A. de, Pecile, A., Saito, S., Tani, F.: "Functional and morphological observations on the rat pituitary grafted into the anterior chamber of the eye." *J. Endocrinol.* **19**: 164-172 (1959).

C77,283/59

In hypophysectomized rats with pituitary grafts in the anterior chamber of the eye, STH and gonadotropic activity vanished, but some ACTH and TTH secretion continued despite severance of all connections with the ME. It is contended that "vasopressin may be the hypothalamic neurohumor involved in ACTH secretion, and that the ACTH-releasing activity of Guillemin's fraction D may be accounted for by its vasopressin content."

Hertz, R.: "Gonadotropin and adrenocorticotropin from rat pituitary homografts as manifested by host response to chorionic gonadotropin and amphenone." *Endocrinology* **66**: 842-844 (1960).

C87,506/60

In hypophysectomized rats bearing four adenohypophyseal grafts under the renal capsule, amphenone causes adrenal enlargement which is lacking in hypophysectomized controls. "Since the adrenomegalic response to amphenone is mediated through suppression of corticoid production by the rat adrenal, these pituitary grafts apparently also maintain a degree of reciprocal functional relationship with the adrenal cortex."

Yoshida, S., Sayers, G.: "ACTH in pituitary grafts." *Fed. Proc.* **20**: 183 (1961).

D3,973/61

In hypophysectomized rats with pituitary autografts under the kidney capsule or hypothalamus, vasopressin increased blood ACTH, whereas DOC suppressed it. [The brief abstract does not lend itself to critical evaluation (H.S.).]

C98,302/61

In hypophysectomized rats with pituitary homotransplants placed under the ME, "there were pronounced gains in body weights, activation of the thyroids, structural repair of the adrenals and the reproductive organs, and fertility."

Halász, B., Pupp, L., Uhlarik, S.: "Hypophysiotrophic area in the hypothalamus." *J. Endocrinol.* **25**: 147-154 (1962).

D38,273/62

Adenohypophyseal tissue of thirty-day-old rats was transplanted into different regions of the hypothalamus of adult recipients. Grafts in the ventral hypothalamus retained a normal histologic appearance despite lack of any contact with the ME. A "hypophysiotrophic" area was detected by the location of basophils in the graft and the maintenance of the target organs for anterior lobe hormones, except that the gonads sometimes underwent atrophy. Grafts in other sites did not maintain their structure or preserve the integrity of the target glands.

Foster, R. Jr., Rothchild, I.: "On the secretion of corticotrophin by the homotransplanted pituitary gland in the rat." *Acta Endocrinol. (Kbh.)* **39**: 371-384 (1962).

D20,802/62

In hypophysectomized rats with pituitary homotransplants under the kidney capsule, ether anesthesia, histamine or unilateral adrenalectomy failed to cause adrenal ascorbic acid depletion, although the grafts contained approximately normal amounts of ACTH. ACTH release presumably depends upon di-

rect contact with the CNS. "The possibility that the slightly heavier adrenals in the transplant bearing animals might be due to a non-ACTH factor secreted by the transplant was also considered."

Critchlow, V., Lipscomb, H. S., Guillemin, R.: "Effect of CRF on maintenance of the adrenocorticotrophic function of anterior pituitary grafts." *J. Endocrinol.* **25**: 465-472 (1963).

D55,920/63

In rats with their own adenohypophysis transplanted under the kidney capsule, "prolonged administration of CRF has maintained synthesis of ACTH by the transplanted pituitary as well as its ability to release ACTH when acutely stimulated by CRF. These results were not duplicated by the administration of lysin-vasopressin or α -MSH in conditions identical to the ones used for studying CRF, and using doses equivalent to the vasopressor and melanophoretic activities of this particular preparation of CRF."

Halász, B., Pupp, L., Uhlarik, S., Tima, L.: "Further studies on the hormone secretion of the anterior pituitary transplanted into the hypophysiotrophic area of the rat hypothalamus." *Endocrinology* **77**: 343-355 (1965).

F46,916/65

In hypophysectomized rats with anterior lobe transplants, restoration of the target glands depended entirely on the location of the grafts. The structure of the thyroid and adrenals was best preserved after transplantation in contact with the ME; in these rats even compensatory hypertrophy following unilateral adrenalectomy, as well as goiter subsequent to methylthiouracil, were evident. Contact with the ME was not necessary for preservation of gonadotropic hormone secretion. Grafts placed in distant brain regions or under the renal capsule were ineffective.

Flament-Durand, J.: "Observations on pituitary transplants into the hypothalamus of the rat." *Endocrinology* **77**: 446-454 (1965).

F49,804/65

Pituitaries of ten-day-old rats were im-

planted into the hypothalamus of adult rats. Grafts located in the hypophysiotropic region contained numerous basophils. This was particularly striking in the case of grafts attached to the arcuate nuclei, which took the appearance of castration cells after hypophysectomy or castration. The effects of grafts in different locations on other target glands are also described.

Evans, J. S., Nikitovitch-Winer, M. B.: "Reactivation of hypophysial grafts by continuous perfusion with median eminence extracts (MEE)." *Fed. Proc.* **24**: 190 (1965).

F35,942/65

Bovine ME extracts, continuously infused through the renal artery in young hypophysectomized rats with pituitary autografts in the kidney, elicited ovarian follicles, with enlargement of the adrenal and thyroid. This work furnishes "direct evidence that the hypothalamic neurohumors act not only as 'releasing' factors but also have tropic effects on many other phases of adenohypophysial function."

Schalch, D. S., Reichlin, S.: "Plasma growth hormone concentration in the rat determined by radioimmunoassay: influence of sex, pregnancy, lactation, anesthesia, hypophysectomy and extrasellar pituitary transplants." *Endocrinology* **79**: 275-280 (1966).

F69,338/66

In rats, plasma STH levels become undetectable after hypophysectomy, and intraocular pituitary transplants fail to raise them. Brief periods of ether anesthesia depress STH levels only in male rats.

Schurr, P. H.: "Techniques and effects of hypophysectomy, pituitary stalk section and pituitary transplantation in man." In: Harris, G. W. and Donovan, B. T., *The Pituitary Gland*, Vol. 2, pp. 22-48. London: Butterworths, 1966.

Gittes, R. F., Kastin, A. J.: "Effects of increasing numbers of pituitary transplants in hypophysectomized rats." *Endocrinology* **78**: 1023-1031 (1966).

F66,264/66

Intrastrain intramuscular pituitary transplants in weanling rats showed no homograft reactions and maintained body growth as well as the development of target organs. These effects were proportional to the number of pituitaries implanted, and with the grafting of thirty glands, they actually exceeded the norm. Presumably, ectopic pituitaries produce only small amounts of hormones, "but the aggregate output of 10 or

30 such glands brought about somatotropic, gonadotropic and mammatrophic changes not previously reported in hypophysectomized female rats bearing ectopic pituitary transplants."

Kendall, J. W., Allen, C.: "Brain-dependent ACTH secretion from multiple heterotopic pituitaries." *Proc. Soc. Exp. Biol. Med.* **122**: 335-337 (1966). F67,274/66

In hypophysectomized rats, heterotransplants of adult rat pituitary do not take well, and single grafts from even immature rats produce too little ACTH to maintain adrenal weight and function. However, in hypophysectomized rats with multiple pituitary transplants from two- to three-week-old donors, adrenal weights and corticosterone discharge remain essentially normal. "Removal of the entire forebrain, but not decortication, in these animals reduced corticosterone secretion nearly to values found in hypophysectomized control animals. These results indicate that heterotopic pituitary ACTH secretion is dependent on some subcortical portion of the forebrain."

Kendall, J. W., Stott, A. K., Allen, C., Greer, M. A.: "Evidence for ACTH secretion and ACTH suppressibility in hypophysectomized rats with multiple heterotopic pituitaries." *Endocrinology* **78**: 533-537 (1966). F62,883/66

Rats hypophysectomized five weeks after transplantation under their renal capsules of ten pituitaries from ten- to twenty-day-old donors maintained nearly normal adrenal weights as well as plasma and adrenal corticosterone levels. At autopsy, there was evidence of anterior and intermediate lobe tissue growth. "Suppression of corticosterone secretion by dexamethasone was similar in both transplanted and intact animals, indicating that contiguity of the pituitary with the hypothalamic median eminence is not essential for the suppression of ACTH secretion by corticosteroids."

Nikitovitch-Winer, M. B., Evans, J. E., Kiracofe, G. H.: "Hypophysiotropic effect of hypothalamic humoral factors." 2nd Int. Congr. on Hormonal Steroids, Milan, 1966, *Int. Congr. Ser. No. 111*, p. 95. Amsterdam and New York: Excerpta Medica, 1966. J13,140/66

In rats, pituitary autografts under the kidney capsule rapidly showed dedifferentiation and loss of functional activity. Continuous infusion of ovine ME extracts through the

renal artery for six to thirty-eight days caused adrenal and thyroid stimulation, whereas in the controls these organs became completely atrophic.

Review of the literature and personal observations indicating that severance of the connections between the hypothalamus and adenohypophysis increases LTH secretion and lactation. This has been observed after stalk section, as well as following heterotopic pituitary transplantation after hypophysec-tomy (25 refs.).

Ducommun, S., Guillemin, R.: "Maintenance of normal morphology in adenohypophyseal transplants by topical administration of hypothalamic extracts with a simple method for transplantation in a pneumodermal pouch." *Proc. Soc. Exp. Biol. Med.* **122**: 1251-1255 (1966). F72,632/66

Purves, H. D., Sirett, N. E.: "Corticotrophin secretion by ectopic pituitary glands." *Endocrinology* **80**: 962-968 (1967). F75,878/67

In hypophysectomized adult rats, five neonatal pituitaries implanted under the kidney capsule partially maintained adrenal weight, but the peripheral plasma corticosterone levels were not significantly higher than in hypophysectomized controls. One hour after stress (ether, urethane, hemorrhage, restraint), significant elevations of peripheral plasma corticosterone were noted. The response to hemorrhage in the graft-bearing rats was inhibited by dexamethasone at very low dose levels, which were ineffective in normal controls. Infusion of lysine-vasopressin released corticotropin from the grafts, but only at very high dose levels. "The results are ascribed to an accumulation of a physiological corticotrophin releasing factor in the peripheral circulation leading to a delayed release of corticotrophin from the grafts."

Vernikos-Danellis, J., Trigg, L. N.: "Feedback mechanisms regulating pituitary ACTH secretion in rats bearing transplantable pituitary tumors." *Endocrinology* **80**: 345-350 (1967). F77,039/67

In rats bearing ACTH-producing pituitary tumors (MtT-F₄), there was a direct relationship between the increase in adrenal weight and the decrease in anterior pituitary weight and pituitary ACTH content. Plasma

ACTH remained near normal until about the sixth week after implantation, when blood corticosterone levels rose despite an 80 percent reduction in pituitary ACTH. At this time, stress (laparotomy under ether) doubled the plasma ACTH level, but this increase was abolished by hypophysectomy. Tumor implantation one day prior to adrenalectomy prevented the increase in plasma ACTH that occurred three weeks after the operation. Apparently, "in the absence of corticoids, an extrapituitary source of ACTH may inhibit adenohypophysial ACTH synthesis and secretion." ["Short loop feedback"] (H.S.)]

Yoshimura, F., Harumiya, K., Ishikawa, H., Ohtsuka, Y.: "Differentiation of isolated chromophobes into acidophils or basophils when transplanted into the hypophysiotrophic area of hypothalamus." *Endocrinol. Jap.* **16**: 531-540 (1969). H24,086/69

Sirett, N. E., Kendall, J. W.: "Hypothalamic control of ACTH release from ectopic pituitary glands." *Endocrinology* **85**: 784-788 (1969). H17,162/69

In rats with multiple adenohypophyseal homografts in their kidneys, plasma corticosterone levels were increased following the removal of the cerebral cortex, and this effect was diminished by subsequent extirpation of the entire forebrain. After removal of all the forebrain except a hypothalamic island, plasma corticosterone levels were 108 percent of the initial value. Stalk- and ME-extract injections into such graft-bearing

ing, hypophysectomized rats raised plasma corticosterone within thirty to sixty minutes. Presumably, "ACTH release from ectopic pituitaries is primarily dependent on a neurohumor of hypothalamic origin passing into the general circulation."

Peng, M. T., Pi, W. P., Wu, C. I.: "Growth hormone secretion by pituitary grafts under the median eminence or renal capsule." *Endocrinology* **85**: 360-365 (1969).

H15,826/69

As indicated by the growth of hypophysectomized rats, it is suggested that "the anterior pituitary transplanted under the median eminence can synthesize and secrete adequate growth hormone, although slightly less than in normal rats; and that the anterior pituitary transplanted underneath the renal capsule can also synthesize and secrete growth hormone as well as the graft placed under the median eminence if thyroxine is given daily."

Csernus, V., Lengvári, I., Halász, B.: "Data on the localization of CRF-producing neural elements." *Gen. Comp. Endocrinol.* **22**: 360 (1974). H83,188/74

Adenohypophyseal tissue was implanted in different hypothalamic regions of rats, and then the pituitary was removed. ACTH secretion was estimated by plasma corticosterone levels and was found to be raised only in those rats in which the implant was in contact with the ME. It is concluded that only the ME contains enough CRF to cause a significant ACTH discharge.

ACTH

In rats, an ACTH discharge occurs almost immediately after exposure to a stressor, since adrenalectomy performed ten minutes following an EP injection does not prevent stress eosinopenia.

In man, plasma corticoid concentrations during severe stress may exceed those obtained by maximal doses of exogenous ACTH. Nevertheless, even when plasma corticoids are already greatly elevated under the influence of stress, additional ACTH treatment can cause a further increment. Presumably, factors other than adrenal secretion may play an important part in the elevation of blood corticoid levels during stress.

Curiously, the ACTH content of the posterior lobe is very high in some species, occasionally equalling that of the adenohypophysis. In vitro, the rat adrenal can liberate corticosterone and aldosterone under the influence of anterior or posterior hypophyseal ACTH.

It has been claimed that in anxious patients, the plasma contains a "precortico-

trophin or adrenal weight-maintenance factor (AWMF)" in concentrations exceeding the ordinary ACTH, described as "ascorbic acid depletion factor (AADF)." The adrenal weight factor (also designated as AWF) is allegedly involved in the regeneration of enucleated adrenals under the influence of separate hypothalamic centers, whereas the neurohypophysis is involved in the discharge of the ascorbic acid factor (AAF) in response to systemic, but not emotional, stressors. Investigators have not pursued this type of research much further, and it is still uncertain whether ascorbic acid discharge and adrenal regeneration are actually regulated by two chemically distinct types of ACTH. However, these effects of ACTH upon the adrenal may be dissociated. For example, in hypophysectomized rats, ACTH causes an almost immediate rise in adrenal vein corticosterone and ascorbic acid content, but the latter soon falls below the initial values, while the former continues to rise. The weight increase also outlasts the effect of ACTH upon corticoid secretion.

Single unit action potentials, measured after deposition of minute amounts of dexamethasone in the immediate extracellular environment of individual cells, showed that steroid-sensitive neurons exist in the cortex, dorsal hypothalamus and thalamus. These were also sensitive to microelectrophoretically-applied NEP and acetylcholine. The predominant action of the former was inhibition, that of the latter, stimulation. In the adenohypophysis, ACTH-producing cells can be identified with peroxidase-labelled antibody, by special stains and by EM characteristics. However, all these techniques still require perfection.

Undoubtedly, ACTH stimulates the adrenal cortex most frequently to secrete glucocorticoids. There is good evidence that the hormone also enhances mineralocorticoid secretion, although perhaps mainly through increased production of steroids other than aldosterone.

ACTH

(See also our earlier stress monographs, p. xiii)

Love, W. D.: "Failure of adrenalectomy immediately following stress to prevent eosinopenia in rats." *Proc. Soc. Exp. Biol. Med.* **75**: 639-641 (1950). B54,242/50

In rats, adrenalectomy ten minutes after EP injection does not prevent stress eosinopenia. Apparently, ACTH and corticoid discharge occurs almost immediately following application of the stressor.

Tyler, F. H., Sandberg, A. A., Eik-Nes, K.: "Adrenal cortical reserve and its relation to stress." *J. Clin. Invest.* **32**: 608 (1953). B82,998/53

In man, plasma 17-OHCS concentrations during severe stress may exceed those obtainable by maximal doses of exogenous ACTH. Nevertheless, in such cases when plasma steroids are already greatly elevated, additional ACTH treatment can cause a further increment. "These findings suggest that factors other than adrenal secretion may

play an important role in the production of elevated steroid levels."

Sayers, G.: "Factors influencing the level of ACTH in blood." In: Wolstenholme, G. E. W. and Millar, E. C. P., *Ciba Foundation Colloquia on Endocrinology*, Vol. 11, pp. 138-149. London: J & A Churchill, 1957. C42,020/57

Review and personal observations on the stressors causing increased ACTH secretion and test techniques for its bioassay in the blood.

Mialhe-Voloss, C.: "Posthypophyse et activité corticotrope" (The posterior lobe of the hypophysis and corticotrophic activity). *Acta Endocrinol.* **28** Supp. 35: 1-96 (1958). C52,008/58

The ACTH content of the posterior lobe is essentially the same as that of the anterior pituitary in cattle. Somewhat smaller concentrations of ACTH are also present in the posterior lobe of the duck and rat. Their corticotrophic activity is not due to MTH (about 250 refs.).

Mialhe-Voloss, C., Baulieu, E. E.: "Étude qualitative des corticostéroïdes libérés par la surrénale du rat in vitro sous l'influence des hormones corticotropes antéhypophysaire et posthypophysaire" (Qualitative study on corticosteroids released by the rat adrenal in vitro, under the influence of corticotrophic hormones from the anterior and posterior lobes of the hypophysis). *C.R. Acad. Sci. (Paris)* **346**: 639-642 (1958). D1,182/58

In vitro, the rat adrenal, as such or after addition of anterior or posterior hypophyseal ACTH, liberates corticosterone and aldosterone. Under these conditions, ACTH extracted from the anterior or posterior lobe is equally effective in stimulating more corticosterone and aldosterone secretion.

Nowell, N. W.: "Studies in the activation and inhibition of adrenocorticotrophin secretion." *Endocrinology* **64**: 191-201 (1959).

C63,783/59

In neurohypophysectomized rats, adrenal ascorbic acid depletion could be produced by cold, hypertonic saline and bell-ringing. A distinction is made between ascorbic acid factor (AAF) and adrenal weight factor (AWF) as two variants of ACTH. The neurohypophysis participates in the release of AAF, which is regulated by separate nerve centers in the hypothalamus. Enucleated adrenals regenerate under the influence of AWF, which is believed not to depend upon hypothalamic centers. "The neurohypophysis is involved in the release of ACTH/AAF in response to systemic stresses but not to emotional ones."

Persky, H., Maroc, J., Conrad, E., Breejen, A. D.: "Blood corticotropin and adrenal weight-maintenance factor levels of anxious patients and normal subjects." *Psychosom. Med.* **21**: 379-386 (1959). D2,894/59

In anxious hypercorticoid patients, the plasma level of "precorticotropin or adrenal weight-maintenance factor (AWMF)" is more significantly increased than that of the classic ACTH or ascorbic acid depletion factor (AADF).

Lipscomb, H. S., Nelson, D. H.: "Dynamic changes in ascorbic acid and corticosteroids in adrenal vein blood after ACTH." *Endocrinology* **66**: 144-146 (1960). J12,365/60

In hypophysectomized rats, the ascorbic acid and corticosterone levels of adrenal vein blood rise immediately after small doses of ACTH, but then corticosterone continues to

increase, whereas ascorbic acid falls below pre-ACTH values.

D17,639/64

In dogs, ACTH increases not only glucocorticoid but to some extent also aldosterone secretion. Both these corticoids are produced at a subnormal level after hypophysectomy.

Ducommun, P., Ducommun, S., Jobin, M., Kraicer, J., Mialhe, P., Mialhe-Voloss, C., Fortier, C.: "Synthèse et libération d'ACTH à la suite d'une agression aiguë chez le rat surrénalectomisé" (Synthesis and liberation of ACTH following acute stress in the adrenalectomized rat). *Schweiz. Med. Wochenschr.* **94**: 892-893 (1964).

G17,137/64

In adrenalectomized rats, laparotomy raised the blood ACTH level within five minutes but contrary to earlier claims, no increase in pituitary ACTH could be detected during the first ten minutes. Presumably, ACTH synthesis does not predominate. The subsequent fall in both pituitary and blood ACTH is ascribed to the fact that the synthesis of the hormone is more markedly inhibited than its release during the later stages of the stress response.

Wied, D. de: "Effects of peptide hormones on behavior." In: Ganong, W. F. and Martini, L., *Frontiers in Neuroendocrinology*, pp. 97-140. New York, London and Toronto: Oxford University Press, 1969. E10,614/69

Review of the effects exerted by ACTH, vasopressin and MTH upon behavior.

Steiner, F. A., Ruf, K., Akert, K.: "Steroid-sensitive neurones in rat brain: anatomical localization and responses to neurohumours and ACTH." *Brain Res.* **12**: 74-85 (1969). H28,002/69

Microelectrophoresis allows deposition of minute amounts of soluble compounds in the immediate extracellular environment of single cells in the CNS, and permits direct monitoring of the local response by recording single unit action potentials. In rats, it has been shown with this technique that dexamethasone-sensitive cells can be identified accurately and localized in the hypothalamus and midbrain, scattered over wide areas. The large majority of these cells are clearly inhibited, but some are activated. No steroid-sensitive neurons were found in the cortex, dorsal hypothalamus or thalamus. The steroid-sensitive neurons were responsive to microelectrophoretically-applied NEP and acetylcholine. The predominant action of the former was inhibition, that of the latter was stimulation. ACTH activated the steroid-sensitive neurons. Presumably, "specific nerve cells in the hypothalamus and midbrain are sensitive to both hormonal and humoural factors and involved in negative and positive feedback actions of the hormones."

"Corticotropin cells were stellate and possessed processes that ended on the walls of

sinusoids. Corticotropin cells composed a small percentage of the total cell population, and were distributed throughout the gland except that they were less common posteriorly, superiorly, and immediately alongside the pars intermedia. Alteration in size of corticotropin cells was related directly to change in corticotropin content of the gland as effected by differing physiological conditions."

Nakane, P. K.: "Classifications of anterior pituitary cell types with immunoenzyme histochemistry." *J. Histochem. Cytochem.* **18**: 9-20 (1970). G72,551/70

With the peroxidase-labeled antibody method, it was possible to localize the adenohypophyseal cells responsible for the secretion of ACTH, STH, FSH, LH and LTH (28 refs.).

Siperstein, E. R., Miller, K. J.: "Further cytophysiologic evidence for the identity of the cells that produce adrenocorticotrophic hormone." *Endocrinology* **86**: 451-486 (1970). H22,201/70

EM studies of the pituitaries of cortisol-treated intact or adrenalectomized rats led to the conclusion that the so-called "adrenalectomy cells" are the site of ACTH secretion and that these can also be identified in intact animals by their characteristic ultrastructure.

Hodges, J. R., Mitchley, S.: "Effect of prolonged treatment with tetracosactrin on hypothalamo-pituitary-adrenal function in the rat." *Br. J. Pharmacol.* **43**: 804-813 (1971). G87,789/71

Prolonged treatment with tetracosactrin (synthetic ACTH) increases the size of the adrenal cortex and its sensitivity to ACTH, while suppressing the circadian rhythm of, and the stress-induced rise in, endogenous ACTH production.

Kolanowski, J., Salvador, G., Crabbé, J.: "Influence de l'agression chirurgicale sur la sensibilité du cortex surrénal à la corticotropine exogène" (Influence of surgical stress on adrenocortical sensitivity to exogenous corticotropin). *Ann. Endocrinol. (Paris)* **33**: 211-215 (1972). H57,788/72

Following surgical stress, the plasma cortisol increase produced by a standard dose of ACTH is augmented.

Lantos, C. P., Dahl, V., Cordero-Funes, J. R., Nicola, A. F. de: "A correlation study between adrenal function and the duration of sustained ACTH treatments in the rat."

Acta Physiol. Lat. Am. **23**: 277-287 (1973).

J9,058/73

In rats, chronic experiments with natural and synthetic ACTH preparations showed that both tropins, especially β^{1-24} corticotropin, provoke alterations in some adrenal parameters. The synthetic peptide demonstrated a marked dissociation between its trophic and secretion-stimulating properties, and natural ACTH decreased aldosterone/corticosterone ratios. Changes in adrenocortical responsiveness may partly account for the triphasic nature of the G.A.S.

Péczely, P., Szokoly, P. M.: "The effect of acute and chronic stimulation on ACTH cell of the pigeon's adenohypophysis." *Gen. Comp. Endocrinol.* **22**: 367 (1974).

H83,210/74

In pigeons, acute insulin hypoglycemia and fourteen-day treatment with metyrapone were studied in connection with their effect upon the epsilon cells (which were light red by Herland's stain). "Insulin stress causes a strong hypertrophy of the ACTH cells. The endoplasmic reticulum shows an extreme hyperplasia, and the quantity of the secretion granules and the ACTH content of the pars distalis decrease. Metyrapone treatment causes hypertrophy and hyperplasia of the ACTH cells. The quantity of the endoplasmic reticulum increases; the cisternae are dilated, and they form vesicles. A great number of secretory granules appear, mainly on the periphery of the cells. The ACTH content of the pars distalis increases." These findings agree with the assumption that the epsilon cells of birds are the source of ACTH, and that acute stimulation and chronic stimulation lead to different EM changes.

Pratt, J. H., Melby, J. C.: "Alterations in aldosterone metabolism induced by adreno-

corticotropin (ACTH)." *Program Amer. Soc. Clin. Invest.*, 66th Ann. Meeting, p. 62a. Atlantic City, N.J., 1974. H88,771/74

In man, "repository ACTH injected every 12 h for 6 days induced a five-fold increment in the aldosterone secretion rate and a four-fold increment in urinary tetrahydroaldosterone excretion by day 6, whereas plasma concentrations of aldosterone did not change significantly." It appears that increased mineralocorticoid activity after ACTH is due almost exclusively to the enhanced production of nonaldosterone mineralocorticoids. Probably, "the augmented metabolic clearance rate for aldosterone after ACTH stimulation can to an extent regulate aldosterone activity and may be a mechanism for escape from aldosterone effect."

Schulster, D.: "Adrenocorticotrophic hormone and the control of adrenal corticosteroidogenesis." *Adv. Steroid Biochem. Pharmacol.* **4**: 233-295 (1974). J15,156/74

Review of the intimate enzymatic mechanisms regulating the secretion of corticoids under the influence of ACTH (about 160 refs.).

Miller, L. H., Kastin, A. J., Sandman, C. A., Fink, M., Veen, W. J. van: "Polypeptide influences on attention, memory and anxiety in man." *Pharmacol. Biochem. Behav.* **2**: 663-668 (1974). J18,229/74

In man, ACTH_{1-24} had no effect on the mental activities examined, but ACTH_{4-10} "served to improve visual memory, decrease anxiety, reinstitute a previously habituated alpha blocking response in the occipital EEG, and generally influence the occipital EEG toward a pattern consistent with increased attention. The results were taken to suggest a direct polypeptide influence on CNS attentional mechanisms."

ACTH Feedback

The fact that a rise in the corticoid level of the blood inhibits further ACTH secretion has long been known, and will be discussed in another section. However, in addition to this "long-loop" biofeedback, there exists a "short-loop," self-regulating mechanism in which ACTH itself acts back upon the pituitary (either directly or through suppression of CRF secretion), to inhibit the continued production of corticotropin once its release has been initiated.

Thus, it was found that in adrenalectomized rats, exogenous ACTH reduces the ACTH content and weight of the hypophysis, and that homotransplants of adenohy-

pophyseal tissue in the hypothalamus of the rat causes adrenocortical atrophy as a consequence of decreased ACTH secretion.

Some investigators reported that ACTH increases, whereas cortisone decreases, the ACTH content of the rat pituitary, but during exposure to a standardized stressor, exogenous ACTH blocks the usual ACTH release from the hypophysis. Presumably, this is why the hormone accumulates in the gland when large amounts of it are suddenly administered.

In rats after adrenalectomy, the pituitary ACTH concentration rapidly increases, but at least two weeks are required to establish a stable balance in which both the content and the secretion of hypophyseal ACTH are high.

Implantation of solid ACTH into the ME of the rat depresses blood corticosterone levels, whereas similar implants in the cerebral cortex or pituitary are ineffective. In adrenalectomized rats given ACTH, nucleolar changes in the hypothalamic neurons also suggest a short-loop feedback mechanism. Several observations imply that the receptors for this negative biofeedback are in the ME.

Injection of ACTH into hypophysectomized-adrenalectomized rats reduces hypothalamic CRF, and it is presumably through this effect that the short-loop feedback inhibits ACTH secretion.

The suppression of ACTH discharge by exogenous ACTH during stress is a typical extra-adrenal action of the hormone.

ACTH Feedback

(See also our earlier stress monographs, p. xiii)

Gemzell, C. A., Heijkenskjöld, F.: "Effect of corticotrophin on the content of corticotrophin in the pituitary glands of adrenalectomized rats." *Acta Endocrinol.* **24:** 249-254 (1957). C41,922/57

In adrenalectomized rats, long-acting ACTH reduced the ACTH content and the weight of the pituitary.

Halász, B., Szentágothai, J.: "Über die unmittelbare Rückwirkung einer vom Hypophysenvorderlappen erzeugten Substanz auf den Hypothalamus" (The immediate retroactive effect on the hypothalamus of a substance produced in the adenohypophysis). *Acta Physiol. Acad. Sci. Hung. Supp.* **14:** 6 (1958). J12,874/58

Homotransplants of adenohypophyseal tissue into the hypothalamus of rats cause adrenocortical atrophy as a consequence of decreased ACTH production. Presumably, ACTH itself can act back on the adenohypophysis to inhibit ACTH secretion.

Kitay, J. I., Holub, D. A., Jailer, J. W.: "Hormonal regulation of pituitary adrenocorticotropicin." *Proc. Soc. Exp. Biol. Med.* **97:** 165-169 (1958). C47,220/58

As judged by in vitro bioassays, "ACTH administration and adrenalectomy both resulted in a striking increase in pituitary ACTH content. Epinephrine and cortisone administration were both followed by significant depletion of pituitary ACTH."

Kitay, J. I., Holub, D. A., Jailer, J. W.: "Extra-adrenal action of exogenous ACTH; inhibition of pituitary ACTH secretion." *Fed. Proc.* **17:** 87 (1958). C51,673/58

In adrenalectomized rats, exogenous ACTH increases, whereas cortisone decreases, the ACTH content of the pituitary. During exposure to a standardized stressor, exogenous ACTH inhibits the usual ACTH release from the adenohypophysis. Presumably, that is why the hormone accumulates in the gland when it is exogenously administered.

Hodges, J. R., Vernikos, J.: "Influence of circulating adrenocorticotrophin on the pituitary adrenocorticotrophic response to stress in the adrenalectomized rat." *Nature* **182:** 725 (1958). C61,601/58

In rats, adrenalectomy first increases the ACTH content of the pituitary, but at least two weeks are required before it adapts itself to secrete and maintain a great excess of this hormone. Tests performed at various intervals during this time showed that the

greatest increase in circulating ACTH occurred in rats with the lowest initial blood levels, and apparently the high serum level of ACTH inhibits its own secretion through an "auto-feedback" mechanism.

Kitay, J. I., Holub, D. A., Jailer, J. W.: "Inhibition of pituitary ACTH release: an extra-adrenal action of exogenous ACTH." *Endocrinology* **64**: 475-482 (1959).

C66,580/59

The stress-induced (scalding) ACTH depletion of the pituitary in adrenalectomized rats is inhibited by pretreatment with ACTH, which also blocks the fall in adrenal ascorbic acid during ether anesthesia in intact rats. Presumably, exogenous ACTH can inhibit the production of endogenous ACTH, which is an additional extraadrenal action of this hormone.

Halász, B., Szentágothai, J.: "Control of adrenocorticotrophic function by direct influence of pituitary substance on the hypothalamus." *Acta Morphol. Acad. Sci. Hung.* **9**: 251-261 (1960).

D15,080/60

Homotransplantation of adenohypophyseal tissue into the infundibular recess of the rat causes involution of the fasciculata of the adrenals. Transplantation of other tissues into the same location or homotransplantation of pituitary into other parts of the hypothalamus have an inverse effect. "The possibility of an automatic self-control of adrenocorticotrophic function by a direct hormonal feedback action from the pituitary on the hypothalamus is discussed on the basis of the results."

Stark, E., Fachet, J., Mihály, K.: "Pituitary and adrenal responsiveness in rats after prolonged treatment with ACTH." *Can. J. Biochem. Physiol.* **41**: 1771-1777 (1963).

E22,584/63

Following several daily ACTH injections, rats become increasingly sensitive to the corticosterone-discharging effect of this hormone. Reduced adrenal stimulation during the stage of resistance of the G.A.S. cannot be ascribed, therefore, to a diminished sensitivity to this hormone, but presumably results from decreased ACTH secretion. After prolonged ACTH treatment, the release of endogenous ACTH by stress (formalin) is also reduced.

Porter, J. C., Klaiber, M. S.: "Relationship of input of ACTH to secretion of corti-

costerone in rats." *Am. J. Physiol.* **207**: 789-792 (1964). F22,653/64

Dávid, M. A., Fraschini, F., Motta, M., Martini, L.: "Short' feedback loops and the control of pituitary function." *Program 47th Meeting Endocrinol. Soc.*, p. 27. New York, 1965. F39,943/65

In rats, implantation of solid ACTH into the ME depresses blood corticosterone levels, whereas similar implants in the cerebral cortex or the pituitary are ineffective, as are implants of LH or FSH in the ME. Thus, in addition to the receptors sensitive to corticoids, control of pituitary function may also be achieved through "short feedback loops," in which the signals are given by anterior pituitary hormones.

Vernikos-Danellis, J., Anderson, E., Trigg, L., Dickinson, J.: "Feedback mechanisms regulating ACTH secretion." *Program 47th Meeting Endocrinol. Soc.*, p. 27. New York, 1965. F39,944/65

In rats bearing ACTH-producing tumors, "inhibition of ACTH secretion by maximal endogenous levels of corticoids is slow to develop and even under conditions when such high levels persist for a considerable length of time the response to stress is not completely prevented. Furthermore, in the absence of corticoids an extra-pituitary source of ACTH may inhibit adenohypophysial ACTH synthesis and secretion."

Motta, M., Mangili, G., Martini, L.: "A 'short' feedback loop in the control of ACTH secretion." *Endocrinology* **77**: 392-395 (1965). F46,923/65

In the rat, permanent implants of synthetic ACTH into the ME depressed blood corticosterone, "suggesting that a 'short' feedback loop might link synthesis and/or release of ACTH to pre-existing levels of the hormone."

Ifft, J. D.: "Further evidence on an 'internal' feedback from the adenohypophysis to the hypothalamus." *Neuroendocrinology* **1**: 350-357 (1965-66). G44,209/65-66

In adrenalectomized rats given ACTH, nucleolar changes in the hypothalamic neurons suggest a short feedback mechanism.

Szentágothai, J., Flerkó, B., Mess, B., Halász, B.: *Hypothalamic Control of the Anterior Pituitary. An Experimental-Morphological Study*, p. 399. Budapest: Akadémiai Kiadó, 1968. E7,567/68

Extensive monograph critically discussing personal experiments and the literature on

hypothalamic control of various anterior pituitary hormones, with a brief chapter (22 pages) dealing with ACTH secretion during stress. "It seems very probable that the hypothalamus is responsible for the maintenance of basal ACTH secretion as well as for the pituitary ACTH response to stress. The hypothalamic influence on the pituitary might be mediated by CRF produced by the hypophysiotrophic area. The hypophysiotrophic area seems to be able to produce and release this substance in the absence of nervous connexions but for the preservation of normal ACTH secretion neural afferents to the area are required. These afferents might come from various hypothalamic and extrahypothalamic (limbic system, reticular formation, etc.) structures and are excitatory as well as inhibitory in character which probably do not affect directly pituitary ACTH secretion but might act through the hypophysiotrophic area by modulating the synthesis and release of CRF. ACTH secretion is also influenced by blood corticoid levels and there is some indication that ACTH itself might play some role in controlling pituitary ACTH function. Although the question of the site of corticoid and ACTH action is not settled as yet, it could be assumed that this action is also mediated—at least partly—through the hypothalamus." There is some evidence in favor of the "short-circuit feedback" influencing various anterior pituitary hormones, including ACTH, through direct inhibition of the hypothalamus. For example, ACTH implants in the ME significantly depress blood corticosterone levels, but the "short feedback" may not always be direct in the anatomic sense, that is, conveyed over a particular vascular link permitting the reverse flow through the portal vessels of the pituitary. It may also act through the systemic circulation (several thousand refs.).

Motta, M., Fraschini, F., Martini, L.: "Short' feedback mechanisms in the control of anterior pituitary function." In: Ganong, W. F. and Martini, L., *Frontiers in Neuroendocrinology*, pp. 211-253. New York, Lon-

don and Toronto: Oxford University Press, 1969.

Motta, M., Sterescu, N., Piva, F., Martini, L.: "The participation of 'short' feedback mechanisms in the control of ACTH and TSH secretion." *Acta Neurol. Belg.* **69**: 501-507 (1969).

G70,812/69

Review of the literature and personal observations on rats indicate that "ACTH secretion can be automatically controlled through a 'short' feedback mechanism, whose receptors are located in the median eminence (ME) of the hypothalamus. The 'short' feedback control of ACTH secretion appears to be of the 'negative' (inhibiting) type. TSH [TTH] secretion may also be automatically regulated by circulating levels of TSH."

Stark, E., Ács, Z., Szalay, K. S.: "Further studies on the hypophyseal-adrenocortical response to various stressing procedures in ACTH-treated rats." *Acta Physiol. Acad. Sci. Hung.* **36**: 55-61 (1969).

G74,546/69

In rats, some but not all stressors fail to increase ACTH secretion after a five-day treatment with ACTH.

Seiden, G., Brodish, A.: "Physiological evidence for 'short-loop' feedback effects of ACTH on hypothalamic CRF." *Neuroendocrinology* **8**: 154-164 (1971).

H47,192/71

In long-term hypophysectomized rats (one to six weeks), CRF rises to three or four times its normal level, but no significant increase is seen two to four days after hypophysectomy. CRF activity in the hypothalamus of chronically adrenalectomized rats is half that found in normals, but the elevated hypothalamic CRF levels in hypophysectomized rats are not altered by subsequent adrenalectomy. Injection of ACTH into hypophysectomized, adrenalectomized rats reduces hypothalamic CRF to one-eighth the levels in similarly operated controls. "These results suggest a direct action of ACTH on the hypothalamus, and provide evidence for a 'short-loop' feedback system between ACTH and CRF."

Extra-adrenal Actions of ACTH

At first it was thought that ACTH acts only by stimulating the secretion of corticoids. The first demonstration of a direct "nonadrenal-mediated" action of ACTH was the finding that it stimulates the preputial glands in adrenalectomized-ovariectomized rats. From this, it was "concluded that ACTH possesses actions which are not

mediated through either the adrenals or the gonads and which do not even depend upon the simultaneous presence in the body of adrenal or gonadal hormones." Subsequently, this effect was confirmed with highly purified ACTH in doses insufficient to cause significant thymolysis.

Another early, pertinent observation was that, in adrenalectomized-orchidectomized rats, the thymolytic effect of cortisone and other glucocorticoids is considerably enhanced by simultaneous treatment with ACTH. The latter, however, has no direct effect upon the thymus, as evidenced by the absence of the thymolytic action after adrenalectomy in otherwise untreated rats.

The previously described "short-loop" feedback action of ACTH, through which the hormone inhibits its own excessive secretion, may also be regarded as an extra-adrenal action. The same is true of the recently-discovered neuropsychologic actions of ACTH.

Extra-adrenal Actions of ACTH

(See also our earlier stress monographs, p. xiii)

Jacot, B., Selye, H.: "A non-adrenal-mediated action of ACTH on the preputial glands." *Proc. Soc. Exp. Biol. Med.* **78**: 46-48 (1951). B59,872/51

First demonstration of a direct, "non-adrenal-mediated" action of ACTH on the preputial glands of adrenalectomized, ovariectomized rats. "It is concluded that ACTH possesses actions which are not mediated through either the adrenals or the gonads and which do not even depend upon the simultaneous presence in the body of adrenal or gonadal hormones."

Jacot, B., Selye, H.: "On extra-adrenal actions of adreno-corticotrophic preparations." *Endocrinology* **50**: 254-258 (1952). B62,775/52

Even a considerably purified preparation of ACTH stimulates the growth of the preputial glands in female adrenalectomized and ovariectomized rats. This effect is detectable at a dose that does not cause significant thymolysis.

Selye, H., Jacot, B.: "On the effect of various steroids upon the extra-adrenal thymolytic action of ACTH." *Acta Endocrinol. (Kbh.)* **9**: 333-336 (1952). B62,780/52

In adrenalectomized and orchidectomized rats, the thymolytic effect of cortisone is greatly enhanced by simultaneous administration of ACTH, which has no such action under similar conditions if given in combination with DOC or estradiol. Apparently, the thymolytic action of cortisone is enhanced

(conditioned) by ACTH, which has no direct effect on the thymus by itself.

Hess, M., Rennels, E. G., Finerty, J. C.: "Response of preputial and adrenal glands of hypophysectomized rats to ACTH." *Endocrinology* **52**: 223-227 (1953). D41,911/53

In rats, ACTH has a direct effect upon the preputial glands, increasing their weight and depleting them of ascorbic acid. After hypophysectomy the response of the adrenal and preputial glands remains normal. It is noteworthy that although there is no demonstrable relationship between the adrenal cortex and preputial glands, their reaction to ACTH is essentially the same.

Engel, F. L.: "Extra-adrenal actions of adrenocorticotropin." *Vitam. Horm.* **19**: 189-227 (1961). E5,711/61

Review on all the extra-adrenal actions of ACTH (about 200 refs.).

Yip, S. Y., Freinkel, R. K.: "The direct effect of ACTH on the rat preputial gland." *J. Invest. Dermatol.* **43**: 389-393 (1964). F25,543/64

Confirmation of earlier reports that ACTH stimulates the growth of the preputial glands in adrenalectomized, castrated rats. This direct effect of ACTH has also been confirmed *in vitro* by the enhancement of lipogenesis upon addition of ACTH (13 refs.).

Deckx, R., Moor, P. de, Denef, C., Raus, J.: "Effect of adrenalectomy, sham operation or ACTH on the cortisol metabolizing enzymes of rat liver homogenate." *Metabolism* **14**: 264-270 (1965). F32,028/65

In female rats, the direct effect of ACTH on the metabolism of cortisol by liver homogenate differs from that of stress. These circumstances may explain the many apparent contradictions concerning the effect of stress upon the overall rate of corticoid metabolism (21 refs.).

Wied, D. de: "Effects of peptide hormones on behavior." In: Ganong, W. F. and Martini, L., *Frontiers in Neuroendocrinology*, pp. 97-140. New York, London and Toronto: Oxford University Press, 1969.

E10,614/69

Review of the effects exerted by ACTH, vasopressin and MTH upon behavior.

E8,170/69

Review of numerous publications reporting extra-adrenal actions of ACTH which undoubtedly play an important role in the pathogenesis of the G.A.S. (45 refs.).

Non-Glucocorticoid-like Actions of ACTH

The preputial gland-stimulating effect of exogenous ACTH, which we just discussed, is not duplicated by either endogenous or exogenous glucocorticoids.

Furthermore, by using the granuloma pouch technique, it was shown in the rat that exogenous ACTH suppresses inflammation and causes thymicolymphatic atrophy only at dose levels insufficient to induce general catabolism with loss of body weight. Certain testoids inhibit the catabolic effects of heavy ACTH overdosage, but not those of cortisol; conversely, under suitable conditions, DOC can suppress the catabolic effects of cortisol but not those of ACTH.

There is also some evidence that ACTH increases, whereas glucocorticoids decrease, fear-motivated behavior and arousal in the rat.

Not Glucocorticoid-like Actions of ACTH

(See also our earlier stress monographs, p. xiii)

Selye, H.: "Selective alteration of certain ACTH and glucocorticoid effects by androstan derivatives." *Metabolism* 4: 403-415 (1955).

C2,007/55

By use of the granuloma pouch technique, it was found that "only ACTH preparations can suppress inflammation and cause thymicolymphatic involution at dose-levels which do not suffice to induce any pronounced catabolism in the rat. MAD and allied testoids suppress the catabolic effects of ACTH but not those of cortisol, while DCA suppresses

the catabolic effects of cortisol but does not prevent those of ACTH."

Weiss, J. M., McEwen, B. S., Silva, M. T. A., Kalkut, M. F.: "Pituitary-adrenal influences on fear responding." *Science* 163: 197-199 (1969).

H5,347/69

In passive avoidance situations, hypophysectomized rats show less, and adrenalectomized rats more, fear than normals. This may be due to the fact that the hypophysectomized rat lacks ACTH, which increases arousal, whereas adrenalectomized rats have enhanced ACTH production. Presumably, ACTH and glucocorticoids have opposite effects on the regulation of fear-motivated behavior.

Non-Stress-like Actions of ACTH

It is interesting that some of the actions of ACTH are not duplicated by stress, even when the latter obviously elicits an overproduction of this hormone. Thus, as we saw before, the preputial glands are stimulated by ACTH but not by stress, even

under conditions where stress greatly increases endogenous ACTH secretion. It is difficult to explain this peculiar phenomenon unless we assume that during stress a number of factors specifically inhibit certain actions of ACTH.

Non-Stress-like Actions of ACTH

(See also our earlier stress monographs, p. xiii)

Deckx, R., Moor, P. de, Denef, C., Raus, J.: "Effect of adrenalectomy, sham operation or ACTH on the cortisol metabolizing enzymes of rat liver homogenate." *Metabolism* **14**: 264-270 (1965). F32,028/65

In female rats, the direct effect of ACTH on the metabolism of cortisol by liver homogenate differs from that of stress. These circumstances may explain the many apparent contradictions concerning the effect of

stress upon the overall rate of corticoid metabolism (21 refs.).

Vecsei, P., Kessler, H.: "In vivo conversion of corticosterone into aldosterone in rats treated with ACTH or submitted to stress." *Experientia* **26** 1015-1016 (1970).

H31,555/70

Studies on the in vivo conversion of corticosterone to aldosterone in rat adrenals revealed a diminution after ACTH pretreatment, but not upon chronic exposure to stressors. It is concluded that the adrenocortical effect of stress is not mediated exclusively through ACTH secretion.

Somatotrophic Hormone (STH, GH)

The effect of stress upon STH secretion is dependent upon a number of complex factors that condition this response, through concurrent changes in the secretion of STH-releasing factor or the metabolism of STH. When indirect indicators are used, alterations in the responsiveness of peripheral tissues to this hormone further condition STH activity.

In rats, starvation reduces the synthesis of STH-releasing factor by the hypothalamus, thus indirectly decreasing STH secretion. EP, NEP and dopamine injected into the lateral ventricles depleted pituitary STH, whereas several other neurohormones tested did not share this effect. Hence, STH secretion has been considered to be controlled by catecholamines.

The tibia cartilage test indicates that many but not all stressors increase plasma STH. Presumably, catecholamines and hypothalamic STH-releasing factor act as mediators, but the sensitivity of the peripheral target organs must also be taken into account.

According to other investigators, radioimmunoassayable STH concentrations in the plasma of rats are suppressed by various stressors as well as by dexamethasone, even after adrenalectomy. These findings, if confirmed, suggest that STH secretion is subject to corticoid feedback, and that stress can inhibit the release of this hormone independently of adrenocortical activation.

NEP and dopamine at doses known to deplete pituitary STH in rats caused disappearance of STH-releasing factor from the hypothalamus and its appearance in the plasma of hypophysectomized rats but not of intact controls. In the intact rats, very small doses of intraventricular NEP depleted pituitary STH activity. This catecholamine appears to be the normal synaptic transmitter for the discharge of STH-releasing factor from neurosecretory neurons. Electrolytic lesions in discrete hypothalamic areas reduced pituitary and plasma radioimmunoassayable STH and impaired somatic

growth. Hypothalamic STH-releasing neurohormone has been purified, isolated and synthesized. It represents a straight-chain acidic decapeptide.

There is also some evidence suggesting the existence of an inhibitory hypothalamic factor. Serum STH is greatly increased in man following injection of L-dopa (a dopamine precursor) whereas antiadrenergic drugs depress the STH level. Several observations suggest that STH is subject to "short-loop" feedback, through which it blocks its own secretion.

In rats with large medial hypothalamic lesions, STH secretion during stress is impaired but not abolished. Presumably, in the absence of both stimulatory and inhibitory neural impulses, the pituitary somatotrophs are capable of autonomous secretion.

In children, exhausting bicycle exercise caused a simultaneous increase in plasma STH and cortisol, indicating that the two hormones can be discharged concurrently.

Somatostatin (STH-RIF, SRIF). Somatostatin is the STH release-inhibiting hormone. It is a peptide, presumably secreted by the ME, that impedes STH secretion not only under resting conditions, but also when it is augmented by exercise, insulin, arginine, NEP injected into the ventromedial nucleus, and electric stimulation of the amygdala or ventromedial nucleus. It appears to act directly on the adenohypophyseal somatotrophs. This conclusion agrees with the finding that intravenous synthetic somatostatin inhibits the STH discharge usually produced by stimulation of the hypothalamic ventromedial and basolateral amygdaloid nuclei. This tetradecapeptide is now available in synthetic form for clinical use. It decreases plasma insulin, glucose and LTH concentrations but raises FFA.

Somatomedin. This factor was previously described as the sulfation factor. It is intimately related to STH secretion, but its possible role in stress reactions has not been clarified. In fact, there may exist several types of somatomedins.

Somantin. This substance appears to be a product of the breakdown of STH. The STH molecule has at least two, perhaps three distinct parts, each eliciting different effects. The tail portion of the molecule, called somantin, inhibits insulin and can produce transient diabetes in partially pancreatectomized rats. Its name is an abbreviation of "somatotrophin antagonist of insulin." The head part has an opposite effect and has correspondingly been called cataglykin. The middle portion of STH between somantin and cataglykin may correspond to somatomedin. The role of these factors in stress has not yet been clarified.

Somatotropic Hormone (STH, GH)

Lundin, M., Schelin, U., Pellegrini, G., Mellgren, J.: "Plasma cell production in the adaptation syndrome." *Acta Pathol. Microbiol. Scand.* **35**: 339-356 (1954).

C9,986/54

In rats, various types of stressors eliciting a typical G.A.S. cause plasma cell proliferation that has been ascribed to increased production of STH.

Halász, B.: "Neural control of growth hormone secretion." Proc. 2nd Int. Congr. Endocrinol., London, 1964. *Int. Congr. Ser. No. 83*, pp. 517-521. Amsterdam and New York: Excerpta Medica, 1965. F48,877/64

Meites, J., Fiel, N. J.: "Effect of starvation on hypothalamic content of 'somatotropin releasing factor' and pituitary growth hormone content." *Endocrinology* **77**: 455-460 (1965). F49,805/65

In rats, starvation reduces the synthesis and release of STH-RF by the hypothalamus,

which results in a decreased STH discharge from the adenohypophysis.

Müller, E. E., dal Pra, P., Pecile, A.: "Influence of brain neurohumors injected into the lateral ventricle of the rat on growth hormone release." *Endocrinology* **83**: 893-896 (1968).

H3,581/68

In rats, EP, NEP and dopamine injected into the lateral ventricle induced depletion of pituitary STH, whereas 5-HT, acetylcholine, vasopressin and oxytocin did not share this STH-releasing effect. Presumably, adrenergic mediators participate in the neurohumoral control of STH secretion.

Müller, E. E., Pecile, A.: "Studies on the neural control of growth hormone secretion." In: Pecile, A. and Müller, E. E., *Growth Hormone*, pp. 253-266. Amsterdam and New York: Excerpta Medica, 1968.

E8,299/68

Observations on rats show that many but not all stressors increase plasma STH (tibia test). Although many similarities in the control of ACTH and STH are apparent, a different threshold of stimulation and/or diverse nervous pathways relaying impulses to the CNS might be the cause of dissociation between their control mechanisms. Stimuli releasing STH act via the hypothalamus, and catecholamines may be considered as mediators of STH-RF.

Wakabayashi, I., Arimura, A., Schally, A. V.: "Effect of adrenocortical hormones on plasma radioimmunoassayable growth hormone (RIA-GH) in rats." *Physiologist* **13**: 332 (1970).

H27,784/70

In rats, radioimmunoassayable STH concentrations in plasma are suppressed by various stressors, as well as by dexamethasone, even after adrenalectomy. Apparently, the stress-induced changes in plasma STH are independent of adrenocortical activation.

Müller, E. E., Pecile, A., Felici, M., Coccochi, D.: "Norepinephrine and dopamine injection into lateral brain ventricle of the rat and growth hormone-releasing activity in the hypothalamus and plasma." *Endocrinology* **86**: 1376-1382 (1970).

H26,874/70

In rats, NEP and dopamine (at doses known to deplete pituitary STH) caused the disappearance of STH-RF activity in the hypothalamus and its appearance in the plasma of hypophysectomized rats but not of intact controls. 5-HT was ineffective in this respect. In intact rats, intravenous NEP diminished pituitary STH activity in very small doses. The hypothalamic site for STH discharge by

catecholamines suggests that NEP is the synaptic transmitter that releases STH-RF from its neurosecretory neurons. This factor can be assayed by pituitary STH depletion following intracarotid injection of hypothalamic extracts or plasma.

Takahashi, K., Daughaday, W. H., Kipnis, D. M.: "Regulation of immunoreactive growth hormone secretion in male rats." *Endocrinology* **88**: 909-917 (1971).

H37,347/71

Plasma immunoreactive STH rose more in gentled rats than in nongentled controls, whereas plasma corticosterone levels were less elevated. In both gentled and nongentled rats, pentobarbital anesthesia caused a significant rise in plasma STH and a corresponding decrease in plasma corticosterone. Ether, hypertonic glucose, 2-deoxyglucose, insulin and EP elicited a marked suppression of plasma STH and an increase in plasma corticosterone, effects which were partly or totally blocked by pentobarbital anesthesia.

Müller, E. E.: "Nervous control of growth hormone secretion." *Neuroendocrinology* **11**: 338-369 (1973).

H71,999/73

Review on the neural control of STH secretion in mammals. Electrolytic lesions in discrete hypothalamic areas reduced pituitary and plasma radioimmunoassayable STH, impaired somatic growth, and diminished STH discharge in response to insulin but not after electric stimulation of brain areas. Hypothalamic STH secretion seems to be governed by an STH-releasing neuropeptide that has been purified, isolated and synthesized, and which represents a straight-chain acidic decapeptide. There is also some proof of an inhibitory hypothalamic factor whose function in STH discharge is not yet clear. STH-RF decreases in the hypothalamus and increases in the plasma when STH secretion is enhanced. Catecholamines play a significant role in the neurohormonal control of STH discharge. Serum STH is greatly increased in man following ingestion of L-dopa (a precursor of dopamine), whereas chlorpromazine, an antiadrenergic drug, depresses the STH level. During deep sleep, STH secretion in man is apparently independent of alterations in brain catecholamine turnover, but like other anterior pituitary hormones, STH is subject to a feedback on itself, which decreases its own discharge (about 150 refs.).

Massara, F., Camanni, F., Molinatti,

G. M.: "Liberazione di ormone somatotropo in seguito a stimolazione alfa-adrenergica nell'uomo" (Somatotropic hormone secretion following α -adrenergic stimulation in man). *Folia Endocrinol.* (Roma) **26**: 476-482 (1973). H83,466/73

Observations in man suggest that stimulation of α -adrenergic receptors excites CNS centers to cause STH secretion.

Winter, J. S. D.: "The metabolic response to exercise and exhaustion in normal and growth-hormone-deficient children." *Can. J. Physiol. Pharmacol.* **52**: 575-582 (1974).

H87,451/74

Exhausting bicycle exercise caused a rise in the STH and cortisol but a fall in the insulin content of the plasma in normal people.

Dunn, J., Arimura, A.: "Serum growth hormone levels following ablation of medial basal hypothalamus." *Neuroendocrinology* **15**: 189-199 (1974). H91,993/74

In rats with large medial hypothalamic lesions, STH secretion after "ether stress" was impaired but not abolished. (The destruction was accomplished by a modified Halász knife with a cross bar which interrupted the vascular supply from the ventral surface of the brain.) Perhaps the simultaneous elimination of stimulation and inhibition by neural impulses largely compensated the effect upon STH release. "The pituitary somatotrophs appear capable of autonomous secretion."

Somatostatin (STH-RIF, SRIF). Vale, W., Brazeau, P., Rivier, C., Rivier, J., Grant, G., Burgus, R., Guillemain, R.: "Biological activities of somatostatin" (abstracted). *Program 55th Ann. Meeting Endocrinol. Soc.*, p. A-118. Chicago, 1973. H73,038/73

Description of somatostatin, a hypothalamic peptide that impedes STH release. In fasted baboons, arginine-stimulated secretion of insulin and glucagon is also inhibited by somatostatin.

"Growth-hormone release-inhibiting hormone." *Lancet* June 8, 1974, pp. 1148-1150. H87,156/74

Brief review of contemporary knowledge on somatostatin. It inhibits STH secretion not only under ordinary conditions, but also when it is augmented by "various stimuli including exercise, insulin-induced hypoglycaemia, sleep, arginine, levodopa, morphine, pentobarbitone, noradrenaline injected into the ventromedial nucleus of the hypothalamus, and electrical stimulation of the amygdala or ventromedial nucleus." Apparently it acts directly on the somatotroph cells of the adenohypophysis (16 refs.).

Brazeau, P., Rivier, J., Vale, W., Guillemain, R.: "Inhibition of growth hormone secretion in the rat by synthetic somatostatin." *Endocrinology* **94**: 184-187 (1974).

H80,841/74

Synthetic somatostatin lowers the circulating level of immunoreactive STH in "gentled" rats; it also prevents or inhibits the rise in plasma STH induced by administration of pentobarbital. In chronic experiments, it decreases the rate of somatic growth.

Martin, J. B.: "Inhibitory effect of somatostatin (SRIF) on the release of growth hormone (GH) induced in the rat by electrical stimulation." *Endocrinology* **94**: 497-502 (1974). H86,286/74

Synthetic somatostatin (SRIF), given intravenously before stimulation of the hypothalamic ventromedial and basolateral amygdaloid nuclei, completely inhibits the usual STH discharge. Apparently, SRIF prevents STH release induced by stimulation of either of these brain regions, suggesting that the site of blockade is in the pituitary itself.

Yen, S. S. C., Siler, T. M., Vane, G. W. de: "Effect of somatostatin in patients with acromegaly. Suppression of growth hormone, prolactin, insulin and glucose levels." *N. Engl. J. Med.* **290**: 935-938 (1974).

H85,536/74

Somatostatin, a hypothalamic polypeptide, suppresses STH secretion in various tissues

in man. This STH-inhibiting factor is a tetradecapeptide which is now available in synthetic form for clinical use. It increases plasma FFA, decreases plasma insulin, glucose and LTH, and depresses STH secretion, not only in acromegaly, but also after exercise, sleep or treatment with arginine, L-dopa, hypoglycemic agents, and so on. It has not yet been shown to play a definite role in the G.A.S. (25 refs.).

Smythe, G. A., Lazarus, L.: "Suppression of human growth hormone secretion by melatonin and cyproheptadine." *J. Clin. Invest.* **54**: 116-121 (1974). H87,405/74

In the rat as in man, STH secretion (stimulated by serotoninergic pathways) can be inhibited by treatment with 5-HT antagonists such as cyproheptadine, and the pineal gland hormone, melatonin. [In this respect, these compounds resemble the actions of somatostatin (H.S.).]

Review on somatomedin, previously known as the "sulfation factor" (about 200 refs.).

Job, J.-C., Rappaport, R.: "Somatomedines et croissance" (Somatomedins and growth). *Arch. Fr. Pédiatr.* **31**: 333-337 (1974). J12,952/74

Review of the literature suggesting that there are several types of somatomedins. [Their possible participation in stress is not discussed, but they are obviously involved in the associated STH secretion (H.S.).]

Somantin. Vargas, L., Bronfman, M., Kawada, M. E.: "Stress, insulin antagonist and transient diabetes mellitus in the rat." *Horm. Metab. Res.* **6**: 275-280 (1974).

H90,727/74

In rats the diabetogenic activity of STH may depend upon an α_2 -glycoprotein that appears in the blood after exposure to various stressors or administration of STH. This substance inhibits insulin and produces transient diabetes in partially pancreatectomized rats. It may be related to somantin, which is the "tail" residue after splitting the STH molecule at the 166 amino acid site. It received its name as an abbreviation of "somatotrophin antagonist of insulin" and has insulin antagonistic properties in vitro. The "head" portion of the STH molecule exerts an opposite effect and has been called "cataglykin" (from the Greek *kata* and *glykos*). In themselves, neither somantin nor cataglykin have STH activity. The intermediate part of the molecule between cataglykin and somantin may be identical with somatomedin. The relationship between somantin and somatostatin is not discussed, although the two substances appear to be closely connected.

Thyrotrophic Hormone (TTH, TSH)

That stress can either increase or decrease thyroid activity, depending upon conditioning circumstances, has already been mentioned in other sections of this volume, for example, in the sections on Hormones and Hormone-like Substances (under Stressors and Conditioning Agents), Thyroid (under Morphologic Changes) and Diseases of Adaptation; it will again be discussed later in this section on Hormonal Mechanisms (under Hormones and Hormone-like Substances: Thyroid).

Here it will suffice to point out that cold increases both plasma TTH and corticosterone levels in the rat, but concurrent exposure to other stressors may suppress the TTH response selectively and enhance corticoid secretion. It has been postulated that contemporaneous stimulation of ACTH and inhibition of TTH secretion during stress are related to depressed hippocampal activity.

Thyrotrophic Hormone (TTH, TSH)

(See also our earlier stress monographs, p. xiii)

Dupont, A., Endrőczi, E., Fortier, C.: "Relationship of pituitary-thyroid and pituitary-adrenocortical activities to conditioned be-

haviour in the rat." In: Ford, D. H., *Influence of Hormones on the Nervous System* (Proc. Int. Soc. Psychoneuroendocr., Brooklyn, N.Y., 1970), pp. 451-462. Basel, München and Paris: S Karger, 1971 (25 refs.).

J12,174/71

Dupont, A., Bastarache, E., Endrőczi, E., Fortier, C.: "Effect of hippocampal stimulation on the plasma thyrotropin (TSH) and corticosterone responses to acute cold exposure in the rat." *Can. J. Physiol. Pharmacol.* **50**: 364-367 (1972). H54,958/72

In rats, exposure to cold increases both plasma TTH and corticosterone, but concurrent minor environmental stress (presence of an observer) suppresses the TTH response and enhances the rise in corticosterone. Concurrent stimulation of the gyrus dentatus of the hippocampus by implanted electrodes restores the TTH response to cold and inhibits the rise in corticosterone. "The concurrent stimulation of ACTH release and inhibition of TSH secretion induced by nonspecific

stress are possibly related to depressed hippocampal activity."

Leppäluoto, J., Ranta, T., Lybeck, H., Varis, R.: "Effect of TRH, and short-term exposure to experimental stress or cold on the serum immunoassayable TSH concentration in the rat." *Acta Physiol. Scand.* **90**: 640-644 (1974). J13,381/74

Various acute stressors temporarily raise plasma TTH levels, but this is followed by a lasting and pronounced decrease. Only cold causes a specific increase in plasma TTH activity. "The inhibition of TSH [TTH] secretion in response to stress refutes the hypothesis that stressful stimuli activate the thyroid gland."

Luteotrophic Hormone (LTH, Prolactin)

The effect of stress upon LTH production has been discussed under Chemical Changes (Hormones and Hormone-like Substances). Like the release of STH, it is subject to so many conditioning factors that accurate generalizations are difficult to formulate.

In rats, various stressors reduce the LTH content of the pituitary. This effect is generally prevented by Nembutal or acid bovine stalk-ME extracts.

Several findings suggest that a hypothalamic inhibitory factor for LTH secretion exists and that its suppression during stress enhances LTH secretion.

Luteotrophic Hormone (LTH, Prolactin)

(See also our earlier stress monographs, p. xiii)

Grosvenor, C. E., McCann, S. M., Nallar, R.: "Inhibition of nursing-induced and stress-induced fall in pituitary prolactin concentration in lactating rats by injection of acid extracts of bovine hypothalamus." *Endocrinology* **76**: 883-889 (1965).

F39,155/65

In rats, nursing and exposure to various stressors reduce the LTH content of the pituitary. Nembutal prevents the fall in LTH after laparotomy and bleeding. Acid extracts of bovine stalk-ME inhibit the fall in pituitary LTH following the combined stimuli of nursing and stress. There may exist "a hypothalamic inhibitory factor in the normal regulation of prolactin release in response to nursing or stress."

MIDDLE (INTERMEDIATE) LOBE OF THE HYPOPHYSIS Melanotrophic Hormone (MTH, MSH)

MTH secretion during stress has been discussed in the section on the Chemical Changes (under Hormones and Hormone-like Substances). It should be kept in mind, however, that MTH is not the only hormone of the intermediate lobe, since the latter is also extremely rich in ACTH.

In rats, one month after adrenalectomy, the ACTH content of the adenohypophysis

increases considerably whereas that of the intermediate lobe remains unchanged. Chronic treatment with cortisol decreases the ACTH concentration in the adeno-hypophysis but not in the pars intermedia. The role of the middle lobe in the metabolism of ACTH is still not clear, but in any event, the production, storage and discharge of ACTH is largely independent of MTH biogenesis and secretion.

**Middle (Intermediate) Lobe of the Hypophysis
Melanotrophic Hormone (MTH, MSH)**

(See also our earlier stress monographs, p. xiii)

Wied, D. de: "Effects of peptide hormones on behavior." In: Ganong, W. F. and Martini, L., *Frontiers in Neuroendocrinology*, pp. 97-140. New York, London and Toronto: Oxford University Press, 1969.

E10,614/69

Review of the effects exerted by ACTH, vasopressin and MTH upon behavior.

Gosbee, J. L., Kraicer, J., Kastin, A. J., Schally, A. V.: "Functional relationship between the pars intermedia and ACTH secretion in the rat." *Endocrinology* 86: 560-567 (1970).

H22,210/70

In rats, autoradiographic studies (thymidine-³H incorporation) showed that only one cell type, restricted to the pars intermedia, responded to altered ACTH secretion with an increase in the label index after adrenalectomy and a decrease after cortisol. Since no changes in plasma or hypophyseal MTH content were found, "it is concluded that there is a functional relationship between the pars

intermedia and ACTH secretion" (29 refs.).

Kraicer, J., Gosbee, J. L., Bencosme, S. A.: "Pars intermedia and pars distalis: two sites of ACTH production in the rat hypophysis." *Neuroendocrinology* 11: 156-176 (1973). H68,125/73

In rats "the concentration of ACTH in the pars intermedia is considerably greater than that in the pars distalis. At 1 month after adrenalectomy, the ACTH concentration in the pars distalis increased 3-fold, while that in the pars intermedia remained unchanged. Following chronic administration of cortisol, the ACTH concentration in the pars distalis fell to 27% of the control, while the fall in ACTH concentration in the pars intermedia was not significant.... Although a relation between the pars intermedia and ACTH is established, this relation is different from that between the pars distalis and ACTH."

Stratton, L. O., Kastin, A. J.: "Avoidance learning at two levels of shock in rats receiving MSH." *Horm. Behav.* 5: 149-155 (1974). J13,633/74

Experiments on rats suggest that MTH may facilitate learning at low but not at high levels of electric shock, which induces stress in a shuttle box.

POSTERIOR (NEURAL) LOBE OF THE HYPOPHYSIS

Data concerning the secretion of posterior lobe hormones have been reviewed in part under Characteristic Manifestations of Stress (Chemical Changes).

Transection of the supraoptico-hypophyseal tract causes atrophy of the posterior lobe and diabetes insipidus in the dog. It also inhibits the stress-induced release of vasopressin.

Both vasopressin and oxytocin injected into the CSF elicit an ACTH discharge, while EP and various stressors inhibit diuresis owing to hypersecretion of vasopressin concurrently with ACTH discharge.

In rats, neurohypophysectomy does not change the adrenal ascorbic acid-depleting effect of ether anesthesia or unilateral adrenalectomy, but partially inhibits these consequences of an ACTH discharge elicited by cold, emotional arousal or EP. It was postulated that psychic stressors act on the ACTH present in the posterior lobe by the

mediation of endogenous EP, whereas neither the posterior lobe nor EP is involved in the corresponding effect of somatic stress. The antidiuretic response to hemorrhage, histamine and painful stimuli is also reduced by posterior lobe extirpation. Vasopressin appears to be involved in the corticotrophic effect of neurogenic stimuli, since posterior lobectomized rats respond to "systemic stressors" (hemorrhage, histamine, nicotine) with a normal increase in plasma-free corticosterone. Conversely, those exposed to "neurogenic stressors" (strange environment, sound, pain) show a decreased response, despite the adrenal enlargement caused by posterior lobectomy.

However, recent investigations suggest that truly selective removal of the posterior and intermediate lobes does not significantly alter normal adenohypophyseal activity during stress.

Posterior (Neural) Lobe of the Hypophysis

(See also our earlier stress monographs, p. xiii)

O'Connor, W. J.: "The effect of section of the supraopticohypophyseal tracts on the inhibition of water-diuresis by emotional stress." *Q. J. Exp. Physiol.* **33**: 149-161 (1946). B36,165/46

In dogs, section of the supraopticohypophyseal tract caused atrophy of the neurohypophysis and diabetes insipidus. In addition, the amount of vasopressin released during emotional stress was greatly reduced and the slow type of inhibition of water-diuresis was almost abolished. In this respect, there was no significant difference between animals with posterior pituitary extirpation and those subjected to tract section.

Martini, L.: "Nuove osservazioni sulla regolazione ormonale della ipofisi anteriore ad opera della ipofisi posteriore: e deduzioni anche sul piano terapeutico" (New observations on hormonal regulation of the anterior hypophysis by the posterior lobe: also, deductions in the therapeutic field). *Clin. Ter.* **7**: 189-206 (1954). C569/54

A review and personal observations on the importance of posterior lobe hormones in the regulation of ACTH secretion. Both vasopressin and oxytocin, injected intravenously or into the CSF, elicit an ACTH discharge, whereas EP and various stressors inhibit diuresis (a sign of vasopressin hypersecretion) with a concurrent ACTH release. Both these phenomena are detectable only in the presence of the pituitary (164 refs.).

Green, J. D.: "Neural pathways to the hypophysis." In: Fields, W. S., Guillemin, R. et al., *Hypothalamic-Hypophysial Interrelationships. A Symposium*, pp. 3-14. Springfield, Ill.: Charles C Thomas, 1956.

tionships. A Symposium, pp. 3-14. Springfield, Ill.: Charles C Thomas, 1956.

C23,833/56

Nowell, N. W.: "Studies in the activation and inhibition of adrenocorticotrophin secretion." *Endocrinology* **64**: 191-201 (1959).

C63,783/59

In neurohypophysectomized rats, adrenal ascorbic acid depletion could be produced by cold, hypertonic saline and bell-ringing. A distinction is made between ascorbic acid factor (AAF) and adrenal weight factor (AWF) as two variants of ACTH. The neurohypophysis participates in the release of AAF, which is regulated by separate nerve centers in the hypothalamus. Enucleated adrenals regenerate under the influence of AWF, which is believed not to depend upon hypothalamic centers. "The neurohypophysis is involved in the release of ACTH/AAF in response to systemic stresses but not to emotional ones."

Smelik, P. G.: "Mechanism of hypophysial response to psychic stress." *Acta Endocrinol. (Kbh.)* **33**: 437-443 (1960). C81,900/60

In rats, neurohypophysectomy does not change the adrenal ascorbic acid-depleting effect of ether anesthesia or unilateral adrenalectomy, but it does partially inhibit the effect of exposure to cold, and it abolishes the effect of emotional disturbance or EP. Presumably, "psychic stress stimuli act on the corticotrophin present in the posterior lobe of the hypophysis by the mediation of endogenous adrenaline, whereas in the case of somatic stress neither the posterior lobe nor adrenaline is involved."

Smelik, P. G.: "The role of the posterior lobe of the pituitary gland in the corticotrophic response to acute stress." *Acta*

Physiol. Pharmacol. Neerl. **9:** 125-126 (1960). C89,917/60

In neurohypophysectomized rats, certain types of stressors no longer produce adrenal ascorbic acid discharge. It is suggested that "emotional stimuli activate the adrenal cortex only in the presence of the posterior lobe, but that somatic stimuli act as normally when the posterior lobe has been removed."

Wied, D. de: "The significance of the antidiuretic hormone in the release mechanism of corticotropin." *Endocrinology* **68:** 956-970 (1961). D7,440/61

In rats, posterior lobe extirpation greatly reduces the antidiuretic response to hemorrhage, histamine or painful stimuli. Exposure of these animals to "systemic stress" (hemorrhage, histamine, nicotine) increases plasma free corticosterone as much as in sham-operated controls. However, "neurogenic stressors" (strange environment, sound, pain) become significantly less effective, although the adrenal is enlarged after posterior lobectomy. These and other observations led the author to conclude that "the

antidiuretic hormone is involved in the corticotrophic effect of neurogenic stimuli."

Smelik, P. G., Gaarenstroom, J. H., Konijnendijk, W., Wied, D. de: "Evaluation of the role of the posterior lobe of the hypophysis in the reflex secretion of corticotrophin." *Acta Physiol. Pharmacol. Neerl.* **11:** 20-33 (1962). D32,829/62

Miller, R. E., Yueh-Chien, H., Wiley, M. K., Hewitt, R.: "Anterior hypophysial function in the posterior-hypophysectomized rat: normal regulation of the adrenal system." *Neuroendocrinology* **14:** 233-250 (1974). H86,430/74

Removal of the posterior and intermediate lobes did not alter normal anterior pituitary function in rats, whether at rest or following application of various stressors.

Vasopressin, Antidiuretic Hormone (ADH), Oxytocin

It has been established beyond reasonable doubt that the antidiuretic hormone (ADH) of the posterior lobe is identical with vasopressin. Various stressors decrease the antidiuretic activity of the pituitary and hypothalamus in the rat, especially during the alarm reaction phase of the G.A.S. Large doses of vasopressin stimulate ACTH secretion even in rats with diabetes insipidus induced by transection of the supraopticohypophyseal tract. It was felt, therefore, that the latter is intimately connected with a discharge of ACTH.

There was much debate about the possibility that vasopressin might be identical with or at least closely related to CRF, but this view has now been almost unanimously abandoned. The CRF activity of early vasopressin preparations was usually due to contamination with CRF. Of course, in the presence of the pituitary, large doses of vasopressin or even of oxytocin can produce an ACTH discharge by acting as stressors. This response is inhibited by hypophysectomy, but is demonstrable even in rats with ocular adenohypophyseal homotransplants. In this event, the posterior lobe hormones are particularly effective when applied topically to the graft; hence, it was concluded that they can act also as neurohumoral transmitters, even though they are less active in this respect than CRF.

In any event, vasopressin release may occur in man without an associated ACTH discharge and vice versa, indicating that endogenous vasopressin is not an indispensable ACTH-releasing factor.

In dogs, injection of minute doses of vasopressin into the third ventricle produced marked rises in the 17-OHCS level of adrenal venous blood, but the same amounts

administered intravenously were ineffective. Oxytocin had no such effect given by either route.

Synthetic arginine vasopressin stimulates ACTH secretion in rats, even after administration of large doses of cortisol, which prevent the typical response to stressors. This is another important point in favor of the hypothesis that vasopressin itself does have some direct ACTH-discharging properties. However, curiously, in dogs, direct arterial perfusion of the adrenal with synthetic lysine vasopressin stimulated cortisol secretion, evidently through some local action independent of the hypophysis. Like effects were obtained with several other synthetic vasopressin derivatives, but in this arrangement, pressor and ACTH activity were independent of each other. On the other hand, similar polypeptides (such as oxytocin), insulin, glucagon, EP and NEP did not cause cortisol secretion, whereas ACTH also raised aldosterone production when perfused through the adrenals of hypophysectomized dogs. Yet a detailed review of the literature published up to the time of these investigations led the author to conclude, "it seems justified to relegate the ADH theory of ACTH release to the emeritus role."

It is characteristic of the confusion in this domain that only a few years later it was found that ACTH-producing pituitary tumors, as well as various types of synthetic or natural vasopressin, were all active in causing ACTH release in proportion to their pressor activity. Hence it was postulated that "vasopressin is the ACTH-releasing hormone" and that even synthetic lysine-vasopressin has "CRF-like" effects. ACTH discharge was elicited by injections of minute amounts of vasopressin into the artery supplying an ACTH-secreting pituitary graft in the hind leg of a rat, whereas 1,500 times this amount of vasopressin given intravenously had no effect. Again it was concluded that "vasopressin may be the ACTH-releasing neurohumor."

In rats, vasopressin placed directly upon the ME after dexamethasone pretreatment produced pronounced ACTH release, but was less active when injected into the adenohypophysis. It was assumed that vasopressin acts directly on the hypothalamus to cause a discharge of endogenous CRF.

In rats with hereditary hypothalamic diabetes insipidus owing to a lack of vasopressin, various stressors raised plasma corticosterone but to a lesser extent than in normal controls. The CRF activity of the ME and the pituitary ACTH concentration were essentially normal in this strain of rats. Hence, it was assumed that although vasopressin is not identical with CRF, "it may play a small role in adrenal cortical response to stress."

In vasopressin-deficient rats with diabetes insipidus, in which stress causes a definite but subnormal increase in plasma corticosterone, in vitro observations suggest that the adrenal glands themselves are relatively insensitive to ACTH. Perhaps the presence of vasopressin during early life may permanently influence adrenal sensitivity.

In rats with the neurohypophysis removed but the adenohypophysis and portal circulation intact, there was no detectable vasopressin in the plasma after stress, despite the high concentration of CRF. Conversely, when the adenohypophysis was removed and the neurohypophysis left intact, there occurred a rise in plasma vasopressin after stress, but no detectable increase in CRF.

In patients with diabetes insipidus, the circadian variations in plasma cortisol are normal. These findings "do not support the view that under physiological conditions vasopressin would be the neurohumoral regulator of ACTH secretion."

In monkeys and in man, synthetic lysine-vasopressin occasionally produced not only corticoid but also STH discharges, although this effect may have been nonspecific.

(ADH), Oxytocin**

(See also our earlier stress monographs, p. xiii)

Nagareda, C. S., Gaunt, R.: "Functional relationship between the adrenal cortex and posterior pituitary." *Endocrinology* 48: 560-567 (1951). B59,637/51

Only in large doses did vasopressin deplete the rat adrenal of ascorbic acid. Large water loads had the same effect.

Kovács, K., Bachrach, D.: "Hypothalamus and water metabolism. Studies on the antidiuretic substance of the hypothalamus and hypophysis." *Acta Med. Scand.* 141: 137-152 (1951). B69,790/51

In rats the hypothalamus contains an antidiuretic substance apparently identical with vasopressin. Various stressors (formaldehyde, hypertonic sodium chloride), as well as adrenalectomy, diminish the antidiuretic activity of the pituitary and hypothalamus. This decrease "following the shock phase of the alarm reaction suggests that, besides the anterior lobe of the pituitary, this system too, takes an active part in defence against non-specific damage" (121 refs.).

McCann, S. M., Brobeck, J. R.: "Evidence for a role of the supraopticohypophyseal system in regulation of adrenocorticotrophin secretion." *Proc. Soc. Exp. Biol. Med.* 87: 318-324 (1954). J9,398/54

In rats, variously placed hypothalamic lesions which block ACTH secretion (as judged by adrenal ascorbic acid depletion, adrenal weight and plasma ACTH) always destroy large areas of the supraopticohypophyseal tract and cause diabetes insipidus. Large doses of vasopressin stimulate ACTH secretion in these rats. "It appears likely, therefore, that destruction of the median eminence is not a necessary condition for blockade of the stress response and that destruction of a large percentage of the supraopticohypophyseal tract is the most constant feature in rats with effective lesions of the hypothalamus."

Mirsky, I. A., Stein, M., Paulisch, G.: "The secretion of an antidiuretic substance into the circulation of rats exposed to noxious stimuli." *Endocrinology* 54: 491-505 (1954). B93,139/54

Mirsky, I. A., Stein, M., Paulisch, G.: "The secretion of an antidiuretic substance into the circulation of adrenalectomized and

hypophsectomized rats exposed to noxious stimuli." *Endocrinology* 55: 28-39 (1954).

B95,024/54

"Exposure of adrenalectomized and hypophsectomized rats to noxious stimuli results in a marked increase in the antidiuretic activity of the plasma. Exposure of cortisone-treated hydrated, hypophsectomized rats to such stimuli results in an antidiuresis. Consequently, neither the adrenal gland nor the hypophysis is the source of the factor responsible for the increased antidiuretic activity of the plasma of animals exposed to noxious stimuli."

Mirsky, I. A.: "Secretion of antidiuretic hormone in response to noxious stimuli." *Arch. Neurol. Psychiatry* 73: 135-137 (1955). C4,174/55

"The same stimuli which can initiate the sequence of events described by Selye as the 'alarm reaction' elicit also an antidiuretic response." The latter has been shown to result from an increase in the vasopressin concentration of the plasma.

Arimura, A.: "The effect of posterior-pituitary hormone on the release of ACTH." *Jap. J. Physiol.* 5: 37-44 (1955).

C6,604/55

Although large doses of vasopressin cause adrenal ascorbic acid depletion in the rat, pretreatment with small doses actually prevents the release of ACTH provoked by EP, histamine or cold.

Guillemin, R., Hearn, W. R.: "ACTH release by 'in vitro' pituitary. Effect of pitressin and purified arginine-vasopressin." *Proc. Soc. Exp. Biol. Med.* 89: 365-367 (1955).

C7,404/55

In a modified tissue culture procedure, rat adenohypophysis increased ACTH release, whereas purified arginine-vasopressin was ineffective. The activity of commercial vasopressin preparations "is attributed to a contaminant of vasopressin of probable hypothalamic origin."

Shibusawa, K., Saito, S., Fukuda, M., Kawai, T., Yoshimura, F.: "On the role of the hypothalamic-neurohypophyseal neurosecretion in the liberation of the adenohypophyseal hormones." *Endocrinol. Jap.* 2: 47-56 (1955). J12,732/55

In various species, vasopressin injection augments ACTH secretion; this hormone "is believed to be the prominent stimulator for the liberation of the pituitary adrenocortical hormone." Yet its release during stress is

said to follow ACTH discharge. [The quaint English used by the authors makes the interpretation of their data difficult (H.S.).]

Martini, L., Morpurgo, C.: "Neurohumoral control of the release of adrenocorticotrophic hormone." *Nature* **175**: 1127-1128 (1955). C7,998/55

Antidiuretic and oxytocic preparations from the posterior pituitary may produce ACTH release upon intravenous injection in intact dogs and rats. Allegedly, these preparations also cause a discharge of TTH and LTH. In rats, vasopressin decreases adrenal cholesterol, but only in the presence of the pituitary. "This demonstrates that cholesterol depletion after injection of posterior pituitary hormones is not due to contamination of the materials injected with adrenocorticotrophic hormone."

Martini, L., Poli, A. de: "Neurohumoral control of the release of adrenocorticotrophic hormone." *J. Endocrinol.* **13**: 229-234 (1956). C15,162/56

In hypophysectomized rats, injection of posterior pituitary hormones failed to cause the usual eosinopenia and adrenal ascorbic acid depletion. However, hypophysectomized rats with ocular adenohypophyseal homotransplants from adult rats responded to both intraperitoneal and intraocular injection of posterior pituitary hormones with eosinopenia and adrenal ascorbic acid depletion. "These results are consistent with the hypothesis that the posterior pituitary hormones act as humoral transmitting agents which, released by the hypothalamus into the hypophysial portal system, can activate the anterior pituitary to discharge ACTH."

Sayers, G.: "Discharge of ACTH from the adenohypophysis of the adrenalectomized rat." *Fed. Proc.* **15**: 162 (1956).

C16,643/56

Even in adrenalectomized rats, stress (ether), vasopressin and EP cause ACTH release. Although synthetic vasopressin is just as effective as the natural product, the results are compatible with the view, but do not prove, that vasopressin is the ACTH-releasing factor.

McCann, S. M.: "The ACTH-releasing activity of extracts of the posterior lobe of the pituitary *in vivo*." *Endocrinology* **60**: 664-676 (1957). F27,982/57

Observations on rats support the hypothesis that vasopressin "may be the neuro-

humor responsible for eliciting ACTH discharge" (32 refs.).

McDonald, R. K., Wagner, H. N., Weise, V. K.: "Relationship between endogenous antidiuretic hormone activity and ACTH release in man." *Proc. Soc. Exp. Biol. Med.* **96**: 652-655 (1957). C45,835/57

In man, vasopressin release may occur without ACTH secretion, and vice versa, under the influence of various stimuli. Presumably, endogenous vasopressin does not act as an ACTH-releasing factor.

Mialhe-Voloss, C.: "Posthypophyse et activité corticotrope" (The hypophyseal posterior lobe and corticotropic activity). *Acta Endocrinol.* **28** Supp. 35: 1-96 (1958).

C52,008/58

Review on posterior pituitary hormones as regulators of ACTH secretion (about 250 refs.).

Wied, D. de, Bouman, P. R., Smelik, P. G.: "The effect of a lipide extract from the posterior hypothalamus and of pitressin on the release of ACTH from the pituitary gland." *Endocrinology* **62**: 605-613 (1958).

C52,310/58

In rats, various lipid extracts of bovine hypothalamus as well as Pitressin (vasopressin) stimulated ACTH secretion. Morphine or cortisol inhibited the effect of the lipid extracts, but only morphine prevented ACTH discharge by Pitressin, which was obtained even after destruction of the ME. "It is concluded that the lipide extract requires the intactness of hypothalamic structures for its action, and that Pitressin contains the specific neurotransmitter."

Royce, P. C., Sayers, G.: "Extrahypothalamic interaction between Pitressin and ACTH." *Proc. Soc. Exp. Biol. Med.* **98**: 70-74 (1958). C54,346/58

Natural vasopressin depletes adrenal ascorbic acid in hypophysectomized rats and potentiates the corresponding action of ACTH, even after destruction of the ME. "Only part of this effect can be explained by release of ACTH from the pituitary since Pitressin will also deplete adrenal ascorbic acid in a lesioned rat which has been decapitated."

Schapiro, S., Marmorston, J., Sobel, H.: "Mobilization of the antidiuretic hormone and the secretion of ACTH following cold stress." *Endocrinology* **62**: 278-282 (1958).

C48,916/58

In both hydrated and dehydrated guinea

pigs, exposure to cold produced a "normal stress response," as determined by the rise in urinary corticoid excretion. The vasopressor activity of the hypothalamus and posterior pituitary was markedly diminished by dehydration. "Apparently, conditions which induce alterations in mobilization of the antidiuretic hormone do not necessarily induce parallel alterations in the secretion of ACTH in response to stress."

Koibuchi, E.: "The effects of hypothalamic lesions of the pituitary-adrenocortical system." *Endocrinol. Jap.* **5**: 89-98 (1958).

C57,340/58

In rats, lesions in the anterior hypothalamus and the anterior part of the medial hypothalamus caused atrophy of the hypophysis and adrenals. These changes were suppressed by vasopressin. "It seemed likely that the control center of ACTH release is found in the anterior hypothalamus or the anterior part of the medial hypothalamus, and that vasopressin accelerates the release of ACTH."

Kwaan, H. C., Bartelstone, H. J.: "Corticotropin release following injections of minute doses of arginine vasopressin into the third ventricle of the dog." *Endocrinology* **65**: 982-985 (1959).

C78,367/59

In dogs, injection of minute doses of vasopressin into the third ventricle produced marked rises in the 17-OHCS level of adrenal venous blood, whereas the same amounts administered intravenously were inactive. Oxytocin had no such effect by either route, even at dose levels twenty times larger.

Chauvet, J., Acher, R.: "Influence de la vasopressine sur la sécrétion de la corticotropine (ACTH)" (The effect of vasopressin on corticotropin [ACTH] secretion). *Ann. Endocrinol. (Paris)* **20**: 111-115 (1959).

C71,285/59

In rats, arginine-vasopressin stimulates ACTH secretion even after administration of large doses of cortisol which prevent the typical response to stressors.

Nichols, B. L. Jr., Guillemin, R.: "Endogenous and exogenous vasopressin on ACTH release." *Endocrinology* **64**: 914-920 (1959).

C69,487/59

Hilton, J. G., Scian, L. F., Westermann, C. D., Kruesi, O. R.: "Effect of synthetic lysine vasopressin on adrenocortical secretion." *Science* **129**: 971 (1959).

C66,821/59

In dogs, direct arterial perfusion of the adrenal with a fluid containing synthetic lysine-vasopressin stimulates cortisol secretion. This effect is local and is not mediated through the adenohypophysis.

Hilton, J. G.: "Adrenocorticotrophic action of antidiuretic hormone." *Circulation* **21**: 1038-1046 (1960).

C90,262/60

In hypophysectomized dogs, direct perfusion of the adrenals with synthetic lysine, arginine or acetyl arginine-vasopressin stimulated the cortex to secrete cortisol. Pressor activity and adrenotropic effects were independent of each other. Similar polypeptides, such as oxytocin, insulin, glucagon and pressor amines (EP, NEP) did not cause cortisol secretion under identical conditions. However, ACTH was active, and it also increased the rate of aldosterone production. "The probable role of arginine vasopressin as an important factor in the stress reaction is considered along with its postulated ability to activate adrenal phosphorylase."

Hilton, J. G., Scian, L. F., Westermann, C. D., Nakano, J., Kruesi, O. R.: "Vasopressin stimulation of the isolated adrenal glands: nature and mechanism of hydrocortisone secretion." *Endocrinology* **67**: 298-310 (1960).

C90,686/60

In hypophysectomized dogs, direct arterial perfusion of the adrenals with synthetic lysine, arginine or acetyl arginine-vasopressin stimulates cortisol secretion. Similar polypeptides, such as oxytocin, insulin and glucagon, as well as EP and NEP, fail to share this effect. ACTH consistently increases aldosterone secretion under identical conditions after hypophysectomy.

D29,083/62

In rats, injection of vasopressin in minute amounts into the artery supplying an ACTH-secreting pituitary graft in the hind leg releases measurable quantities of ACTH, whereas it has no such effect if given intravenously, even at fifteen hundred times higher dose levels. "These findings suggest that vasopressin may be the ACTH-releasing neurohumor."

Rumsfeld, H. W. Jr., Porter, J. C.: "ACTH-releasing activity of bovine posterior pituitaries." *Endocrinology* **70**: 62-67 (1962).

D16,643/62

The ratios of vasopressor- and ACTH-releasing activity in bovine posterior pituitary extracts and arginine-vasopressin were not interdependent.

Goldman, H., Lindner, L.: "Antidiuretic hormone concentration in blood perfusing the adenohypophysis." *Experientia* **18**: 279-280 (1962).

D26,033/62

Contrary to earlier statements, the vasopressin content of blood perfusing the rat

pituitary is sufficient to account for ACTH secretion.

Arimura, A., Long, C. N. H.: "Influence of a small dose of vasopressin upon the pituitary-adrenal activation in the rat." *Jap. J. Physiol.* **12**: 411-422 (1962).

D41,881/62

Grindeland, R. E., Anderson, E.: "Synthetic vasopressin and ACTH release." *Fed. Proc.* **22**: 386 (1963).

G4,454/63

In rats with an ACTH-producing pituitary tumor, vasopressin, synthetic arginine-vasopressin and lysine-vasopressin were all active in causing ACTH release in proportion to their pressor activity. "It is postulated that vasopressin is the ACTH-releasing hormone."

Doepfner, W., Stürmer, E., Berde, B.: "On the corticotrophin-releasing activity of synthetic neurohypophysial hormones and some related peptides." *Endocrinology* **72**: 897-902 (1963).

D67,095/63

In rats, the ACTH-releasing activity of antidiuretic vasopressin and oxytocic posterior pituitary preparations was tested after blockade of ACTH discharge by morphine. "The pressor and the CRF activities of peptides related to the neurohypophysial hormones need not be strictly correlated."

Wied, D. de: "The site of the blocking action of dexamethasone on stress-induced pituitary ACTH release." *J. Endocrinol.* **29**: 29-37 (1964).

F10,254/64

In rats the corticotrophic effect of stressors and lysine-vasopressin was inhibited by subcutaneous dexamethasone, while that of ACTH was not affected. After extensive lesions were produced in the ME, dexamethasone suppressed the corticotrophic action of lysine-vasopressin and of hypothalamic extract. Dexamethasone did not significantly change the ACTH content of the pituitary in either intact or lesioned rats. "It is concluded that the blocking action of dexamethasone is located in the anterior pituitary."

Hearn, W. R., Lazzari, E. P., Weber, E. J.: "Studies on the corticotropin releasing factor (CRF)." *Tex. Rep. Biol. Med.* **22**: 208 (1964).

J12,071/64

Vasopressin could not be separated from CRF activity, and since even synthetic arginine- and lysine-vasopressin release ACTH, "it is concluded that vasopressin itself is most probably the 'physiological corticotropin-releasing factor.'"

Goldman, H.: "Vasopressin modulation of the distribution of blood flow in the unanesthetized rat." *Neuroendocrinology* 1: 23-30 (1966). F52,660/66

Experiments with infusion of vasopressin—mimicking its blood concentration during stress (hemorrhage)—suggest that at least in the rat ACTH secretion may be modulated by the effects of the posterior pituitary hormone upon blood flow in the anterior lobe.

Meyer, V., Knobil, E.: "Stimulation of growth hormone secretion by vasopressin in the rhesus monkey." *Endocrinology* 79: 1016-1018 (1966). F73,022/66

In unanesthetized rhesus monkeys restrained in primate chairs, vasopressin and lysine-vasopressin administered intravenously increase plasma STH levels, but "this action may not be a specific one."

Hedge, G. A., Yates, M. B., Marcus, R., Yates, F. E.: "Site of action of vasopressin in causing corticotropin release." *Endocrinology* 79: 328-340 (1966). F69,345/66

In rats, vasopressin produced a pronounced ACTH release when it was placed directly upon the ME after dexamethasone pretreatment. It was less active when injected into the anterior pituitary. From these and other observations, it was concluded that "vasopressin apparently acted directly on the hypothalamus to cause release of endogenous corticotropin-releasing factor."

McCann, S. M., Antunes-Rodrigues, J., Nallar, R., Valtin, H.: "Pituitary-adrenal function in the absence of vasopressin." *Endocrinology* 79: 1058-1064 (1966).

F74,055/66

In rats that had hereditary hypothalamic diabetes insipidus and which lacked vasopressin, stressors (ether, bleeding) raised plasma corticosterone, but to a significantly lesser extent than in normal controls of the same strain. The CRF activity in the stalk-ME and the pituitary ACTH concentration were essentially the same in the two groups. Presumably, "although vasopressin is not the corticotrophin-releasing factor, it may play a small role in adrenal cortical response to stress."

Anderson, E.: "Adrenocorticotrophin-releasing hormone in peripheral blood: increase during stress." *Science* 152: 379-380 (1966).

F65,555/66

In rats, various stressors, especially laparotomy under ether anesthesia, cause the discharge of CRF and vasopressin (ADH) into

the circulating blood, presumably from the portal circulation of the pituitary. In a footnote the author mentions that subsequent experiments showed that "the ACTH-releasing and antidiuretic activities involve separate hormones. In rats with the posterior pituitary lobe removed, the anterior pituitary and the hypophyseal portal circulation being left intact, there is no detectable ADH in the plasma after stress, but there is a high concentration of ACTH-RH. With the anterior pituitary removed and the entire neurohypophysis being left intact, there is an elevated concentration of ADH in the plasma after stress but no detectable ACTH-RH." [ACTH-RH = CRF (H.S.).]

Gwinup, G., Steinberg, T., King, C. G., Vernikos-Danellis, J.: "Vasopressin-induced ACTH secretion in man." *J. Clin. Endocrinol. Metab.* 27: 927-930 (1967). F85,329/67

In patients given lysine-8-vasopressin, the plasma ACTH concentration was raised, as determined by assays on hypophysectomized rats. Normal plasma to which comparable amounts of vasopressin were added, did not share this effect. Presumably, "vasopressin-induced steroidogenesis in man is principally due to ACTH secretion."

Arimura, A., Saito, T., Bowers, C. Y., Schally, A. V.: "Pituitary-adrenal activation in rats with hereditary hypothalamic diabetes insipidus." *Acta Endocrinol. (Kbh.)* 54: 155-165 (1967). F76,127/67

In rats with hereditary hypothalamic diabetes insipidus, plasma corticosterone concentrations are essentially normal, and they react to stress (ether, histamine, vasopressin, acetylcholine) as do controls. Since these polyuric rats lack vasopressin, the latter is unlikely to be the physiologic CRF. On the other hand, the CRF level in the hypothalamus of these hereditarily stigmatized rats is normal, although their posterior lobe contains no CRF but a normal amount of ACTH.

Czarny, D., James, V. H. T., Landon, J., Greenwood, F. C.: "Corticosteroid and growth-hormone response to synthetic lysine-vasopressin, natural vasopressin, saline solution, and venepuncture." *Lancet* August 20, 1968, pp. 126-129. H1,264/68

In man, both synthetic lysine-vasopressin and natural vasopressin given intramuscularly increased plasma corticoids regularly, but plasma STH rose only in some volunteers. Plasma corticoids and STH also rose in

several patients following intramuscular injection of saline when blood samples were obtained by intermittent venipuncture.

Ukai, M., Moran, W. H. Jr., Zimmermann, B.: "The role of visceral afferent pathways on vasopressin secretion and urinary excretory patterns during surgical stress." *Ann. Surg.* **168**: 16-28 (1968).

G60,105/68

In dogs, partial gastrectomy increases vasopressin secretion about thirtyfold. This response is not modified by transection of the vagal pathways, but it can be eliminated by cervical cordotomy or dorsal rhizotomy, "indicating that the ascending spinal pain pathways were serving as the predominant afferent pathway." The surgical trauma also decreases endogenous creatinine and osmolal clearance, urinary flow and sodium secretion. The vasopressin discharge is ascribed to stress.

Wied, D. de: "Influence of vasopressin and of a crude CRF preparation on pituitary ACTH-release in posterior-lobectomized rats." *Neuroendocrinology* **3**: 129-135 (1968).

H1,565/68

In posterior-lobectomized rats, arginine-vasopressin (unlike carbachol, angiotensin II or crude CRF) failed to elicit the pituitary-adrenal response, but chronic administration of Pitressin almost completely restored the pituitary-adrenal reaction to arginine-vasopressin. Since the corticotropin effect of neurogenic stressors is also reduced by posterior lobectomy, the results support the hypothesis that arginine-vasopressin is involved in the mechanism of ACTH release in response to neurogenic stressors.

Czakó, L., László, F. A., Kovács, K., Faredin, I., Tóth, I.: "Diurnal variations of the plasma cortisol level in diabetes insipidus." *Acta Med. Acad. Sci. Hung.* **26**: 197-201 (1969).

G67,342/69

In patients with diabetes insipidus, the circadian variations in plasma cortisol are normal. Thus, "the results obtained do not support the view that under physiological conditions vasopressin would be the neurohumoral regulator of ACTH secretion."

Wied, D. de: "Effects of peptide hormones on behavior." In: Ganong, W. F. and Martin, L., *Frontiers in Neuroendocrinology*, pp. 97-140. New York, London and Toronto: Oxford University Press, 1969.

H90,222/74

Wiley, M. K., Pearlmuter, A. F., Miller, R. E.: "Decreased adrenal sensitivity to ACTH in the vasopressin-deficient (Brattleboro) rat." *Neuroendocrinology* **14**: 257-270 (1974).

H88,352/74

In vasopressin-deficient Brattleboro rats homozygous for diabetes insipidus, plasma corticosterone concentrations during stress (ether, laparotomy) rose much less than in genetically normal controls. That they did respond to some extent confirms that vasopressin is not identical with CRF. In vitro observations suggest that in the vasopressin-deficient strain the adrenal glands themselves are relatively insensitive to ACTH. The presence of vasopressin in the internal milieu during early life may permanently influence adrenal sensitivity (18 refs.).

Barnett, J. L., Cheeseman, P., Cheeseman, J., Douglas, J. M., Phillips, J. G.: "Adrenal responsiveness in ageing Brattleboro rats with hereditary diabetes insipidus." *Age and Aging* **3**: 189-195 (1974).

J17,972/74

"Although the resting plasma corticosterone levels were drastically depressed in homozygous DI [diabetes insipidus] rats, there was no impairment of the response to stress; the adrenal glands of homozygous rats were significantly more responsive to stress than the corresponding heterozygous rats."

ADRENALS

Changes in adrenal structure, as well as in catecholamine and corticoid secretion during stress have been discussed at length in the sections on the morphologic and chemical characteristics of the G.A.S. Cannon's classic work on the emergency reaction, with the acute discharge of catecholamines from the adrenal medulla and the sympathetic nervous system, upon exposure to fear, rage and hunger, was extensively discussed in our earlier monographs on stress (p. xiii). Here, we give special attention to subsequent investigations in this field, as well as to studies on corticoid production, and to the participation of the adrenal as a whole during the various phases of the G.A.S.

The most prominent adrenal changes during the alarm reaction are a discharge of chromaffin material, mainly EP, from the adrenal medulla, and of corticoids, lipid granules, cholesterol, and ascorbic acid, from the adrenal cortex. At the same time, there is pronounced hyperemia, with an increase in the blood supply of the gland. Soon afterwards, mitotic proliferation begins, especially in the fasciculata, with some functional hypertrophy of virtually all adrenal cells. As the stage of resistance develops, secretory granules accumulate again, both in the medulla and cortex, conjointly with cholesterol and ascorbic acid. Finally, in the stage of exhaustion, the manifestations of the alarm reaction tend to return, but this time often accompanied by necroses or hemorrhages.

These adrenal changes are undoubtedly of a defensive nature. They are useful especially for the acquisition of resistance to stressors that are quantitatively or qualitatively different from those to which the organism was previously exposed. Therefore, adrenalectomy is particularly detrimental during the initial stage of the G.A.S., whereas later it can be relatively well tolerated, despite continued exposure to the evocative stressor. Adrenal atrophy produced by various means, and especially by hypophysectomy, diminishes resistance almost as much as does complete adrenalectomy.

The thymicolymphatic involution characteristic of the G.A.S. is abolished by adrenalectomy following exposure to most stressors, including traumatic injuries, toxic doses of drugs, catecholamines, hemorrhage. The very few agents, such as x-rays and sex hormones, that continue to exert their lympholytic action in the absence of corticoids, do so presumably as the result of a direct effect upon the thymus, lymph nodes, spleen and other lymphatic organs. On the other hand, thyroidectomy, gonadectomy and a great variety of other surgical interventions do not considerably interfere with the thymicolymphatic involution produced by the G.A.S. It has been concluded, therefore, that the latter is the result of increased glucocorticoid secretion. However, after adrenalectomy in rats, maintenance on threshold doses of glucocorticoids (which do not cause considerable thymus involution by themselves) sensitizes them to the development of thymicolymphatic involution under the influence of stressors. This is due to a nonadrenal-mediated conditioning effect of stress that was mentioned previously; its mechanism is still not fully clarified.

The number of circulating lymphocytes and eosinophils roughly parallels the degree of thymicolymphatic involution during stress. This eosinopenia is likewise attributable to increased ACTH and glucocorticoid secretion and can be reproduced by exogenous ACTH and glucocorticoids.

Adrenalectomy increases the ACTH secretion of the pituitary owing to interruption of the corticoid feedback mechanism; this may or may not be associated with a drop

in the ACTH content of the adenohypophysis, depending upon the time elapsed after removal of the adrenals.

In adrenalectomized rats, the blood vessels of the mesoappendix become insensitive to topical application of NEP. This refractoriness is greatly enhanced by stressors but is counteracted by topical or systemic treatment with corticoids. Apparently, conditioning by the latter is necessary to permit the vessels to respond normally to NEP, and at the same time, to protect against toxic amounts of this catecholamine.

In mice, stress two hours after adrenalectomy causes a significant lymphocytosis lasting several hours. This "stress lymphocytosis" is not prevented by splenectomy; hence it cannot be attributed to evacuation of the splenic reservoir.

The effect of partial and complete adrenalectomy, at rest and upon exposure to stressors, will be discussed in the section on the corticoid feedback mechanism.

The hypothalamic CRF rhythm is not significantly affected by adrenalectomy in the rat; presumably it is of neural origin and independent of the corticoid feedback mechanism.

Adrenals

(See also our earlier stress monographs, p. xiii)

Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* **17**: 234-248 (1936). 36,032/36

First detailed description of the "alarm reaction," characterized by adrenocortical enlargement with acute loss of lipids, thymicolympathic atrophy and loss of body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for forty-eight hours or more, large doses of atropine, morphine, formaldehyde or EP). Adrenalectomy and, to a lesser extent, hypophysectomy prevent the thymus involution. "The changes caused by a drug when it is given for the first time will subside later in spite of the continued administration of this drug" but greatly shorten survival. Perhaps the adrenal enlargement, loss of body weight and the other manifestations of the alarm reaction "enable the organism to meet critical situations more efficiently."

Selye, H.: "The significance of the adrenals for adaptation." *Science* **85**: 247-248 (1937). 67,153/37

Rats "previously adapted to such stimuli as muscular exercise, cold or toxic doses of drugs will tolerate exposure to these same stimuli very well, even after the adrenals have been removed, while exposure to the same stimuli invariably kills not-adapted, adrenalectomized controls, with symptoms

characteristic of adrenal insufficiency and of the alarm reaction." Apparently, the adrenals are necessary for the acquisition of adaptation but are not necessary (or much less so) for its maintenance despite continued exposure.

Selye, H.: "Studies on adaptation." *Endocrinology* **21**: 169-188 (1937). 38,798/37

Hypophysectomy lessens the accidental involution of the thymus and adrenalectomy inhibits it completely, but both these operations greatly diminish resistance to all stressors examined. Thyroidectomy and ovariectomy do not considerably interfere with the thymicolympathic involution and splenic atrophy characteristic of the formalin-induced alarm reaction, nor do they significantly increase mortality.

Ingle, D. J.: "The time for the occurrence of cortico-adrenal hypertrophy in rats during continued work." *Am. J. Physiol.* **124**: 627-630 (1938). 75,145/38

In rats, muscular work elicited by faradic stimulation of the gastrocnemius causes adrenal hypertrophy which is prevented by hypophysectomy and hence is ascribed to stress-induced ACTH secretion.

Leblond, C. P., Segal, G.: "Action de la colchicine sur la surrénale et les organes lymphatiques" (Effect of colchicine on the adrenals and the lymphatic organs). *C.R. Soc. Biol. (Paris)* **128**: 995-996 (1938).

A50,424/38

In rats, colchicine produces extremely severe manifestations of the alarm reaction,

including adrenal enlargement and thymic-lymphatic atrophy. Adrenalectomy suppresses these actions of colchicine.

Hungerford, G. F.: "Effect of epinephrine in decreasing number of circulating mononuclear leucocytes in the rat." *Proc. Soc. Exp. Biol. Med.* **70**: 356-358 (1949).

B31,654/49

EP decreases the number of circulating mononuclear leukocytes in intact or adreno-demedullated rats, but does not do so after complete adrenalectomy and only slightly after hypophysectomy.

Sayers, G., Cheng, C. P.: "Adrenalectomy and pituitary adrenocorticotropic hormone content." *Proc. Soc. Exp. Biol. Med.* **70**: 61-64 (1949). B31,736/49

In rats the ACTH content of the pituitary is reduced by 80 percent twenty-four hours after adrenalectomy. Sham adrenalectomy and scalding cause lesser reductions of pituitary ACTH.

Fritz, I., Levine, R.: "Action of adrenal cortical steroids and nor-epinephrine on vascular responses of adrenalectomized rats" (abstracted). *Am. J. Physiol.* **163**: 713 (1950). B54,186/50

By use of the mesoappendix preparation of the rat, it is shown that vasoconstriction following topical application of NEP is impaired by formaldehyde-induced stress, especially after adrenalectomy, but can be restored by topical application of adrenocortical extract. These and other experiments support the concept that corticoids are necessary for the normal response of small vessels to vasoconstrictors.

Fritz, I., Levine, R.: "Action of adrenal cortical steroids and nor-epinephrine on vascular responses of stress in adrenalectomized rats." *Am. J. Physiol.* **165**: 456-465 (1951). B58,944/51

In adrenalectomized rats the blood vessels of the mesoappendix become refractory to topical application of NEP. Stress induced by formaldehyde given subcutaneously does not impair circulation in the mesoappendix of the normal rat but causes sluggishness of flow, and eventually stasis, prior to death after adrenalectomy. These changes can be prevented by Dibenamine, which also prolongs the survival time after formaldehyde treatment of adrenalectomized rats. Apparently, corticoids are necessary to permit the blood vessels to respond normally to NEP

and, at the same time, protect against toxic amounts of NEP.

Ramey, E. R., Goldstein, M. S., Fritz, I., Levine, R.: "Relation of nor-epinephrine and other autonomic agents to vascular collapse of stressed adrenalectomized animal." *Fed. Proc.* **10**: 108 (1951). B57,125/51

In dogs, adrenalectomy decreases the pressor response to NEP. This cannot be corrected by DOC, but adrenocortical extract largely restores normal responsiveness. Glucocorticoids even act topically in sensitizing small splanchnic vessels to NEP.

Dougherty, T. F., Kumagai, L. F.: "Influence of stress stimuli on lymphatic tissue of adrenalectomized mice." *Endocrinology* **48**: 691-699 (1951). B60,246/51

Mice stressed two hours after adrenalectomy developed a significant lymphocytosis lasting several hours; this was the reverse of the response seen in intact animals. After adrenalectomy the lymphatic organs of mice in sublethal anaphylaxis were actually enlarged. The stress lymphocytosis was not prevented by splenectomy, and hence it could not be ascribed to an evacuation of the splenic reservoir. The findings "are compatible with the concept that the stimulus of stress not only augments pituitary adrenocortical secretion which inhibits lymphatic tissue growth, but also augments directly or indirectly, lymphatic tissue growth promoting influences unrelated to adrenocortical secretion."

Goldstein, M. S., Ramey, E. R., Fritz, I., Levine, R.: "Reversal of effects of stress in adrenalectomized animals by autonomic blocking agents. Use of atropine, Banthine and Dibenamine." *Am. J. Physiol.* **171**: 92-99 (1952). B75,440/52

In adrenalectomized rats, resistance to formalin, hemorrhage, forced muscular exercise and cold was increased by autonomic blocking agents, such as atropine, Banthine, Dibenamine and Thephorin. Apparently, in the absence of corticoids, blockade of autonomic stimuli is beneficial.

Flückiger, E., Verzár, F.: "Überdauern der Adaptation an niedrigen atmosphärischen Druck, nachgewiesen an der Wärmeregulation" (Body temperature regulation indicating retained adaptation under reduced oxygen tension). *Helv. Physiol. Pharmacol. Acta* **11**: 67-72 (1953). B92,392/53

In rats exposed to reduced oxygen tension, the body temperature drops but returns to

normal after three to four days. "This 'retained adaptation' is not dependent on the presence of the adrenals. The phenomenon can also be seen in adrenalectomized rats kept alive with corticoids."

Gerschman, R., Gilbert, D. L., Nye, S. W., Nadig, P. W., Fenn, W. O.: "Role of adrenalectomy and adrenal-cortical hormones in oxygen poisoning." *Am. J. Physiol.* **178**: 346-350 (1954). B97,929/54

In rats, adrenalectomy increases survival after exposure to high oxygen pressure. This increase is counteracted by both adrenocortical extract and EP. Evidently, not all stressors are efficiently combatted by adrenal hormones.

Halász, B.: "Der zeitliche Ablauf von Veränderungen des Kernvolumens in der Nebennierenrinde" (The chronologic development of changes in cell nuclear volume in the adrenal cortex). *Acta Morphol. Acad. Sci. Hung.* **8**: 193-198 (1958).

J13,017/58

In the glomerulosa of the rat adrenal cortex, DOC induces a shrinkage of the nuclei during the first three days, which is followed by a swelling; only after the first week does the characteristic diminution in nuclear size become fully evident and persistent. The fasciculata shows no typical variations. ACTH acts mainly on the fasciculata by causing an initial swelling followed by a shrinkage in nuclear size which after three to five days leads to a persistent and considerable enlargement. Earlier data on the histologic actions induced by DOC and ACTH in the adrenal cortex are reviewed (7 refs.).

Hodges, J. R., Vernikos, J.: "Circulating corticotrophin in normal and adrenalectomized rats after stress." *Acta Endocrinol.* **30**: 188-196 (1959). C63,264/59

In adrenalectomized rats the stress of ether anesthesia caused a rapid rise and fall in the blood level of ACTH, as it did in intact controls. ACTH again became detectable in the blood ten days after adrenalectomy, and then it reached a high that persisted for weeks. The increase in the blood level of ACTH caused by anesthesia in adrenalectomized rats depended upon the resting level of the hormone. "The results support the existence of a dual mechanism regulating the secretion of adrenocorticotropic hormone and also provide evidence that its release can be modified by its resting level in the blood." The initial rapid rise in the secretion of

ACTH in response to stress is presumed to be under neural control, whereas the second, more prolonged phase depends predominantly upon the level of corticoids.

Bonfils, S., Rossi, G., Liefooghe, G., Lambing, A.: "'Ulcère' expérimental de contrainte du rat blanc. I. Méthodes. Fréquence des lésions. Modifications par certains procédés techniques et pharmacodynamiques" (Experimental restraint "ulcer" in the white rat. I. Methods. Frequency of lesions. Modifications by some technical and pharmacodynamic procedures). *Rev. Fr. Etudes Clin. Biol.* **4**: 146-150 (1959). J22,385/59

Description of a modification of Selye's restraint technique for the production of stress ulcers in the rat. Adrenalectomy did not influence, whereas cortisone and vagotomy diminished, the incidence of gastroduodenal ulcers.

Koch, B., Mialhe, C., Stutinsky, F.: "Action de diverses agressions (nervieuses ou humorales) sur l'acide ascorbique d'une autogreffe surrénalienne chez le Rat" (The action of various stressors [nervous or humoral] on the ascorbic acid of an adrenal autograft in the rat). *J. Physiol. (Paris)* **53**: 386-388 (1961). J23,527/61

Schapiro, S.: "Pituitary ACTH and compensatory adrenal hypertrophy in stress non-responsive infant rats." *Endocrinology* **71**: 986-989 (1962). D45,372/62

In newborn rats, adrenal ascorbic acid depletion and corticosterone synthesis fail to occur under the influence of stressors, but unilateral adrenalectomy causes pronounced compensatory hypertrophy of the contralateral gland.

Cope, C. L.: *Adrenal Steroids and Disease*, p. 827. Montreal: J B Lippincott, 1964. E4,976/64

Monograph on the role of corticoids in adaptation and disease, with a special section on the diseases of adaptation.

Hodges, J. R., Jones, M. T.: "Changes in pituitary corticotrophic function in the adrenalectomized rat." *J. Physiol. (Lond.)* **173**: 190-200 (1964). D18,782/64

In rats, adrenalectomy caused a rapid fall followed by a slower rise in pituitary ACTH concentration. The ACTH depletion, but not its subsequent repletion, was prevented by corticosterone. Mild stressors that did not significantly affect plasma ACTH in intact rats considerably raised it after adrenalect-

tomy. The stress-induced ACTH discharge was suppressed by small doses of corticosterone in the adrenalectomized rat, but there was no correlation between plasma corticosterone concentration and the degree of ACTH inhibition.

Porter, J. C., Klaiber, M. S.: "Relationship of input of ACTH to secretion of corticosterone in rats." *Am. J. Physiol.* **207**: 789-792 (1964). F22,653/64

Urquhart, J., Li, C. C.: "The dynamics of adrenocortical secretion." *Am. J. Physiol.* **214**: 73-75 (1968). F92,958/68

In hypophysectomized dogs, cortisol secretion was measured by adding ACTH at different rates to the perfused fluid through their adrenals. "The results with sinusoidal variations in ACTH concentration suggested that an apparent 3-min time constant is dominant in the adrenal response to ACTH. Two dynamic models for the adrenocortical response to ACTH are offered. Both models simulate the experimental results and are systems of conservation equations for known and postulated biochemical intermediates in the coupling between ACTH and cortisol biosynthesis."

Urquhart, J., Li, C. C.: "Dynamic testing and modeling of adrenocortical secretory function." *Ann. N.Y. Acad. Sci.* **156**: 756-778 (1969). H10,877/69

A review of the available literature that lends itself to the construction of models representing the various factors that regulate ACTH secretion and actions. Most of the work was performed on perfused canine adrenal glands subjected to several temporal patterns of stimulation by ACTH. [Such models can incorporate all known factors that influence adrenocortical secretion (chemical composition of the blood, blood flow, nervous stimuli, genetic elements, chronologic sequence of all stimulants, and so on), but of course, *in vivo* the number of modifying circumstances is virtually infinite. Hence, these models must necessarily be restricted to a description of known stimuli and modifying circumstances, the sequence of intermediates in biosynthesis and biodegradation of hormones, and the limited number of other variables which can be established only under highly specific conditions; thus they have little predictive value when compared to data amenable to programming in a computer (H.S.).]

Stear, E. B., Kadish, A. H. (eds.): *Hormonal Control Systems*, p. 304. New York: American Elsevier, 1969. E10,611/69

Proceedings of a symposium on biologic control systems, with contributions by various experts on the regulation of corticoid secretion. Special attempts have been made to develop mathematical models that lend themselves to computer simulation. The principal advantage of such systems is expressed as follows: "Computer simulations (models) of biological systems require that the static and dynamic characteristics of all the pertinent components and processes of the systems be identified and quantitatively specified; computer models are truly functional—they can change state with the flow of time, and therefore they expose the incompleteness of knowledge."

Hiroshige, T., Sakakura, M.: "Circadian rhythm of corticotropin-releasing activity in the hypothalamus of normal and adrenalectomized rats." *Neuroendocrinology* **7**: 25-36 (1971). H36,764/71

In the rat the CRF activity of the hypothalamus shows a definite circadian rhythm, with a peak at 18:00 and a minimum at 08:00, which closely parallels plasma corticosterone levels. The CRF rhythm is not significantly affected by adrenalectomy, and hence it is presumably of neural origin, being independent of the negative corticoid feedback mechanism.

Anitesco, C., Contulesco, A.: "Étude de l'influence du bruit et des vibrations sur le comportement des catécholamines dans l'agression sonore vibratoire industrielle" (Studies on the influence of noise and vibration on the behavior of catecholamines in industrial vibratory acoustic stress). *Arch. Mal. Prof.* **33**: 365-372 (1972). G95,398/72

The appearance of a significantly increased amount of VMA in the urine of a group of eighty subjects after four hours of exposure to noise and vibration in a bus construction factory "is interpreted as the expression of the impairment of the neuroendocrine-humoral ratio, by inciting the ascendant activating system." The depression by tranquilizers of the adrenal function by the diminution of VMA and the 17-KS values during night rest when compared to controls show an insufficiency of endocrine supply.

Guidotti, A., Costa, E.: "Association between increase in cyclic AMP and subsequent induction of tyrosine hydroxylase in

rat adrenal medulla. Experiments with swimming stress." *Nauyn Schmiedebergs Arch. Pharmacol.* **282**: 217-221 (1974).

J12,854/74

cAMP and cGMP (cyclic guanosine monophosphate) were separated from the medulla to determine the relationship between them, because from the literature cited it is clear that the induction of tyrosine hydroxylase activity in the chromaffin cells is preceded by changes in these compounds. When rats are placed in cold water "the swimming stress experiments are in agreement with the view that the enhancement of cAMP/cGMP concentration ratios may function as the second messengers for the induction of tyrosine hydroxylase in adrenal medulla" (12 refs.).

Jefcoate, C. R., Simpson, E. R., Boyd, G. S.: "Spectral properties of rat adrenal-mitochondrial cytochrome P-450." *Eur. J. Biochem.* **42**: 539-551 (1974).

J10,533/74

"A pH-sensitive cholesterol complex of cytochrome P-450_{sec} (side-chain cleavage) was quantitated by means of the pregnenolone difference spectrum. Adrenal mitochondria from 'stressed' rats had about twice as much of this cholesterol complex of cytochrome P-450_{sec} as adrenal mitochondria from rats

kept quiescent." The implication of this upon side-chain cleavage of cholesterol and formation of pregnenolone is discussed.

Ray, P. K., Choudhury, S. R.: "Response of solitary adrenal gland to surgical stress." *Histochem. J.* **7**: 127-137 (1975).

J24,030/75

Histochemical observations of various enzymes showed that trauma produces essentially the same response in intact and unilaterally adrenalectomized rats. However, after this operation the enzymatic responses in the remaining gland are significantly delayed by removal of the contralateral gland. "In experiments using ACTH, the overall pattern of esterase activity shows little deviation from that observed in untreated cases in both groups of animals. The findings indicate that in unilaterally adrenalectomized animals, superadded operative stimuli fail to evoke the early response characteristic of the normal adrenal glands. Such latency points to the vulnerability of their existing defense mechanisms. The remarkable similarity of adrenal response with or without exogenous ACTH in these animals suggests that the reason for a delayed response is rooted in the target organ itself, and is not due to an altered plasma ACTH level."

Epinephrine, Norepinephrine (EP, NEP)

Some of the earliest observations on the role of catecholamines in stress were concerned with their effect upon the nervous system.

In man, EP is not only discharged during stress but causes definite neuropsychologic changes when administered to normal individuals. Among these effects are trembling, crying, salivation, sweating, blushing, pallor, palpitations, moaning, shivering, gastrointestinal spasms and different forms of emotional arousal. The predominance of one or more of these symptoms appears to depend upon individual conditioning factors. Nervous mediation may also play a part in such EP-elicited somatic manifestations as polyuria, diarrhea, hypertension, tachycardia, hyperglycemia and glycosuria.

Recently, considerable work has been done on the effects of catecholamines when discharged from, or injected into, certain parts of the CNS. For details about these reactions, the reader should consult the abstract section.

In rats, swimming to exhaustion in cold water depleted brain NEP and 5-HT, but similar changes were also noted following exposure to a variety of other stressors. It was pointed out that this effect could not depend upon regulation by pituitary activity, since it occurred even after hypophysectomy and after treatment with LSD. However, other investigators reported a depletion of brain catecholamines after electroshock, with restoration within about four hours. In one study, electroshock increased NEP in rats' brains, whereas this was not the case after insulin shock.

In kittens, morphine diminished the NEP content of the brain stem concurrently with the EP store of the adrenals. Both these effects were inhibited by barbiturates. Cold and electroshock also decreased brain NEP in rats; this could be prevented by chlorpromazine, phenobarbital or MAO inhibitors. Differential gradient centrifugation of brain stem homogenates showed that NEP and 5-HT have approximately the same localization in the fraction composed almost entirely of nerve ending particles. Apparently, their release from here during stress is inhibited by MAO inhibitors and sedatives.

In seizure-susceptible mice, convulsive attacks produced by sound diminish the NEP content of the brain, especially in its subcortical layer. MAO inhibitors protect against the lethality of the seizures; these have therefore been ascribed to NEP depletion. However, following repeated exposure, the mice become resistant to the convulsive effect, yet even then their brain NEP drops. Perhaps here death depends upon a particularly rapid catecholamine loss.

In ground squirrels, the turnover of labeled NEP and EP was reduced during hibernation in most tissues, but particularly in the brain.

In guinea pigs, mice and rats, various stressors (fighting, electroshock, restraint, intracranial stimulation with implanted electrodes) decrease brain NEP in the cortex, subcortex, cerebellum, hypothalamus and brain stem to approximately the same degree, without significantly changing the brain 5-HT, GABA or dopamine concentration. Possibly, a decrease in brain NEP reflects intense emotional distress. In rats, hypothermia induced by swimming in cold water reduces brain NEP, but this can be prevented by rapid rewarming.

In rats submitted to the stressor effect of bone fractures, labeled EP localizes in particular cells of the hypothalamus (PVN), which may regulate the endocrine and metabolic changes during stress. However, radioactive EP granules could also be seen in other tissues at different times.

Various stressors enhanced the toxicity of D-amphetamine, perhaps through the release of NEP, but only some of those tested caused a significant increase in amphetamine toxicity and a decrease in brain NEP. Dopamine was not affected by these stimuli, possibly because it is distributed in a different way. NEP is located primarily in the hypothalamus and in other brain stem areas believed to represent central components of the sympathetic nervous system, while dopamine is predominantly situated in the basal ganglia associated with the extrapyramidal system.

During the early 1950s, it was thought that EP discharged from the adrenals was the primary factor in eliciting ACTH secretion during stress. Many of the numerous publications defending this view in spite of all the evidence against it will be found in the abstract section. Contrary to some earlier claims, it has been proven that stress does cause ACTH discharge, even in adrenal-demedullated or adrenalectomized rats, as well as after treatment with adrenergic blocking agents. It is undoubtedly true, however, that very large doses of EP, like any other stressor, can cause an ACTH discharge from the pituitary, and in many respects, corticoids and EP can potentiate each other's actions.

As previously stated, catecholamines may have an important part to play as neurohumoral mediators of the ACTH discharge mechanism in the CNS, but these effects do not depend upon the release of catecholamines by the adrenal medulla or by adrenergic nerve endings. The neurohumoral mediator of ACTH discharge is CRF.

In rats, fluorescence microscopy shows that catecholamines are plentiful in the zona palisadica of the ME. This storage is considerably increased after adrenalectomy and

is diminished by cortisol. Presumably, under conditions of increased CRF discharge, the dopamine and NEP content of the nerve terminals in this area rises, whereas blockade of CRF production is associated with an inverse catecholamine response. These and many other observations suggest that an adrenergic mechanism is involved in CRF release from the ME. However, even this often-confirmed conclusion has not remained uncontradicted. Certain investigators have claimed that reserpine (which depletes catecholamine stores) and α -MT (which blocks catecholamine synthesis) markedly reduce brain NEP and dopamine concentrations, but that plasma corticosterone levels remain unchanged in the rat, both at rest and after exposure to a variety of stressors. These findings allegedly suggest that "brain catecholamines do not play an essential role in stress-induced activation of the pituitary-adrenal system." In fact, some investigators are believed to have furnished evidence for a hypothalamic adrenergic system that inhibits ACTH secretion in the dog.

Microelectrophoresis allows deposition of minute amounts of soluble compounds in the immediate extracellular environment of single cells in the CNS, followed by direct monitoring of local single unit action potentials. This technique made it possible to identify dexamethasone-sensitive cells in the hypothalamus and midbrain, scattered over wide areas. Most of these cells are inhibited but some are activated by the steroid. They are also sensitive to electrophoretically-applied NEP and acetylcholine. The predominant action of the former was inhibition, that of the latter, stimulation.

Forced exercise enhances 5-HT and NEP metabolism in the forebrain and brain stem (especially the mesencephalon and pons-medulla regions) of the rat.

An extensive review of the literature led to the conclusion that there exists an adrenergic system in the brain that inhibits ACTH secretion. NEP, rather than dopamine, is generally considered to be responsible for this "tonic inhibition." Drugs that release active catecholamines from nerve endings inhibit ACTH discharge if they can pass the blood-brain barrier or are injected directly into the third ventricle or ME. Stressors deplete brain NEP and increase ACTH secretion. There is NEP and dopamine in the ME of the dog and rat. The NEP-containing neurons probably originate outside the ventral hypothalamus, since deafferentation of the latter causes virtual disappearance of NEP from the island. Dopamine- and NEP-containing neurons end near or on the portal vessels and hence could enter the portal blood flow and act directly on the pituitary, affecting ACTH secretion.

(The cells in the ME which convert neuronal input to humoral output are considered to be "neuroendocrine transducer cells," since they are neither neurons nor endocrine cells, but convert the nervous message into a hormonal one.)

Contrary to much of the previously mentioned literature, a recent publication states that in rats depletion of brain catecholamines by reserpine or 6-hydroxydopamine did not significantly alter the basal circadian rhythm or the stress-induced rise in plasma corticosterone, and the hypothalamic CRF levels remained virtually unchanged. In addition, more than doubling of brain amine concentrations by a MAO inhibitor also failed to alter these parameters. Hence it was concluded that "brain amines are of relatively little importance in the central regulation of ACTH secretion in the rat."

In rats, hypoxia decreased the NEP but not the 5-HT concentration of the forebrain. After implantation of electrodes into the lateral hypothalamus, self-stimulation rates increased while food and water ingestion decreased during the first twelve hours and subsequently returned to normal. "The results suggest a time-related activation of central adrenergic neuronal systems during exposure to hypoxia."

In rats, intraventricular injections of 6-hydroxydopamine (which does not cross the

blood-brain barrier) caused a lasting depletion of brain catecholamines, without affecting 5-HT or peripheral NEP. This was again unaccompanied by any noteworthy change in plasma or adrenal corticosterone, under ordinary conditions or after exposure to stressors. The suppression of corticoid production by dexamethasone likewise remained unaffected. Hence, it was again concluded that NEP is not involved in regulating pituitary-adrenocortical activity at rest or during stress and feedback inhibition.

The many contradictions in the literature on the effect of stressors upon the catecholamine content of nerve centers are probably due to the use of different experimental animals [species, age, sex] and techniques, and variable time intervals after stimulation when determinations are made.

Review on the psychic and particularly the emotional effects of EP injections in man.

Vogt, M.: "Observations on some conditions affecting the rate of hormone output by the suprarenal cortex." *J. Physiol. (Lond.)* **103**: 317-332 (1944). B897/44

In eviscerated dogs and cats, intravenous infusion of EP causes intense stimulation of corticoid secretion which is allegedly direct and not mediated through the pituitary. [The latter statement is based on observations on a single decapitated dog.] This effect is ob-

tained with physiologic doses of EP and is of the order of several times the normal corticoid output. The action is independent of blood pressure and blood flow.

Long, C. N. H.: "The conditions associated with the secretion of the adrenal cortex." *Fed. Proc.* **6**: 461-471 (1947).

40,532/47

A review of the literature and personal observations on guinea pigs and rats suggest that "the stimulation of the elements of the autonomic nervous system with a concomitant release of epinephrine that occurs under a variety of conditions appears to be a major factor in the activation of the adrenotropic secretion from the anterior lobe" (24 refs.).

Gershberg, H., Fry, E. G., Brobeck, J. R., Long, C. N. H.: "The role of epinephrine in the secretion of the adrenal cortex." *Yale J. Biol. Med.* **23**: 32-51 (1950).

B51,987/50

Experiments on intact, hypophysectomized, and adrenal demedullated rats "seem to show without exception that ACTH is the intermediary of the epinephrine activity, and that the site of action of the epinephrine is the anterior lobe."

McDermott, W. V., Fry, E. G., Brobeck, J. R., Long, C. N. H.: "Mechanism of control of adrenocorticotropic hormone." *Yale J. Biol. Med.* **23**: 52-66 (1950).

B51,980/50

Experiments on rats led to the concept that ACTH discharge during stress occurs in two relatively independent and sequential phases. "The first or autonomic phase depends on the reflex secretion of epinephrine which directly activates the anterior pituitary, while the second or metabolic phase is

based upon the rate of utilization of adrenal cortical hormones within the organism." This once-popular concept (many aspects of which are now outdated) is illustrated in Figure 15.

Hume, D. M., Wittenstein, G. J.: "The relationship of the hypothalamus to pituitary-adrenocortical function." In: Mote, J. R., *Proceedings of the First Clinical ACTH Conference*, pp. 134-147. Philadelphia and Toronto: Blakiston, 1950. B46,961/50

A review of the literature and personal observations on dogs lead the authors to conclude that for ACTH release during stress, an intact hypothalamus is necessary to produce some hormonal material that stimulates the anterior lobe. Following operative trauma, intact nervous connections between

the injured area and the brain are indispensable for an ACTH discharge, although EP released by the splanchnics has a direct effect on the hypothalamic center.

Long, C. N. H.: "Regulation of ACTH secretion." *Rec. Prog. Horm. Res.* **7**: 75-97 (1952).
B68,650/52

Review of the mechanism of ACTH secretion, which is thought to be regulated partly by the ACTH and corticoid concentration of the blood (feedback) and partly through direct stimulation by EP and sympathetic nervous stimuli (49 refs.).

Gordon, M. L.: "An immediate response of the demedullated adrenal gland to stress." *Endocrinology* **7**: 13-18 (1952).

B48,952/52

The ascorbic acid concentration of the rat adrenal is constant following enucleation, and the gland exhibits normal ascorbic acid depletion after exposure to stress (insulin, histamine, cold). "It is therefore concluded that the adrenal medulla is not essential for the activation of the pituitary gland by stressing agents."

Vogt, M.: "The role of adrenaline in the response of the adrenal cortex to stress of various kinds, including emotional stress." In: Wolstenholme, G. E. W., *Ciba Foundation Colloquia on Endocrinology*, Vol. 4, pp. 154-166. London: J & A Churchill, 1952.

B76,075/52

Demedullation of the adrenals can still produce adrenal ascorbic acid depletion in rats exposed to various stressors.

Wolfson, W. Q.: "Inadequacy of epinephrine as an activator of the pituitary-adrenal system." *J. Clin. Endocrinol. Metab.* **13**: 125-128 (1953).
B77,156/53

Sandberg, A. A., Nelson, D. H., Palmer, J. G., Samuels, L. T., Tyler, F. H.: "The effects of epinephrine on the metabolism of 17-hydroxycorticosteroids in the human." *J. Clin. Endocrinol. Metab.* **13**: 629-647 (1953).
B82,624/53

In hormone metabolic studies on man, "no evidence was obtained that epinephrine stimulates steroid secretion by the adrenal cortex or modifies peripheral utilization of steroids." It is more probable "that epinephrine produces its adrenocortical-like cellular effects through a potentiation of the action of 17-hydroxycorticosteroids rather than through an effect on their secretion by the adrenal gland."

Hodges, J. R.: "The function of adrenaline in the production of pituitary adrenocorticotrophic activity." *J. Endocrinol.* **9**: 342-350 (1953).
B84,713/53

The adrenal ascorbic acid depletion produced by subcutaneous EP in rats was prevented by DOC but only at certain relative dose levels. Surgical trauma caused adrenal ascorbic acid depletion, even in rats with demedullated suprarenals. Here again, DOC inhibited cortical stimulation. Apparently, EP liberation is not an indispensable prerequisite for stress-induced ACTH production.

Swingle, W. W., Maxwell, R., Ben, M., Fedor, E. J., Baker, C., Eisler, M., Barlow, G.: "Epinephrine and resistance of hypophysectomized and adrenalectomized rats to stressor agents." *Am. J. Physiol.* **177**: 1-6 (1954).
B93,484/54

"The 24-hour adrenalectomized rat is extremely sensitive to intravenous infusions of globin and dextran, and reacts to both by an anaphylactoid syndrome terminating fatally in 87-93% of the animals. Prophylactic fore-treatment with cortisone confers adequate protection. The hypophysectomized rat, despite severe atrophy of the cortex, does not exhibit symptoms when similarly infused. However, when the adrenals are removed from such animals they become sensitized and die within a few minutes after infusion. Medullectomized rats lacking adrenal medullae, but with well regenerated cortices are also quite sensitive and most of them succumb when infused. The data indicate that epinephrine, released from the intact medulla by the stress of infusion, is the agent responsible for the surprising resistance shown by these hypophysectomized rats. Confirmation was obtained by markedly increasing resistance of adrenalectomized as well as adrenalectomized-hypophysectomized rats to globin by repeated pre- and postinfusion injections of epinephrine. Apparently the amine antagonizes the toxic action upon the peripheral circulation of some agent (possibly histamine) released from tissue cells by globin and dextran infusion, and thus prevents the anaphylactoid response to these two stressor agents."

Funkenstein, D. H., Meade, L. W.: "Nor-epinephrine-like and epinephrine-like substances and the elevation of blood pressure during acute stress." *J. Nerv. Ment. Dis.* **119**: 380-397 (1954).

J13,312/55

In rats, EP caused a sharp decrease in the frequency of conditioned avoidance responses and a slight diminution of escape responses. These effects were prevented by phenoxybenzamine.

Euler, U. S. von: *Noradrenaline. Chemistry, Physiology, Pharmacology and Clinical Aspects*, p. 382. Springfield, Ill.: Charles C Thomas, 1956.

C17,899/56

Excellent and extensive monograph on NEP, including discussions of its chemistry, metabolism and release during rest and stress (about 750 refs.).

Kitay, J. I., Holub, D. A., Jailer, J. W.: "Hormonal regulation of pituitary adrenocorticotrophin." *Proc. Soc. Exp. Biol. Med.* **97**: 165-169 (1958).

C47,220/58

As determined by in vitro bioassays, "ACTH administration and adrenalectomy both resulted in a striking increase in pituitary ACTH content. Epinephrine and cortisone administration were both followed by significant depletion of pituitary ACTH."

Egdahl, R. H.: "The differential response of the adrenal cortex and medulla to bacterial endotoxin." *J. Clin. Invest.* **38**: 1120-1125 (1959).

G33,275/59

In dogs, spinal cord transection at C7 abolishes the adrenal medullary discharge by large doses of bacterial endotoxin but leaves febrile, hypotensive and adrenal cortical responses intact. "Epinephrine release is not necessary for the febrile and adrenocortical stimulating effects of endotoxin."

Endrőczi, E., Schreiber, G., Lissák, K.:

"The role of central nervous activating and inhibitory structures in the control of pituitary-adrenocortical function. Effects of intracerebral cholinergic and adrenergic stimulation." *Acta Physiol. Acad. Sci. Hung.* **24**: 211-221 (1963).

G12,029/63

In the cat, pituitary-adrenocortical activation evoked by cholinergic and adrenergic drugs (injected into various areas of the CNS) has been examined. "Carbaminoylcholine and eserine injected into the septum, preoptic region, anterolateral hypothalamus or into the dorsal tegmental area, were found to inhibit pituitary-adrenal activity. Cholinergic chemical stimulation of the medial and caudal hypothalamus, as well as of the posterior hypothalamus and ventral tegmentum resulted in an increase of ACTH secretion. Adrenaline, nor-adrenaline and ephedrine increased ACTH secretion only when injected into the area of the posterior hypothalamus and ventral tegmentum. The suppression of adrenocortical activity in response to the cholinergic stimulation of the inhibitory structures of the forebrain could be blocked by the adrenergic stimulation of the posterior hypothalamus." Apparently, chemical stimulation of the diencephalon and brain stem makes it possible to separate endocrine regulatory activities from complex behavioral reactions.

Paulsen, E. C., Hess, S. M.: "The rate of synthesis of catecholamines following depletion in guinea pig brain and heart." *J. Neuropath. Expt. Neurol.* **10**: 453-459 (1963).

D69,702/63

In guinea pigs, brain catecholamines were restored about four hours after "electroshock stress." This relatively slow rate suggests that the animals sustained an after-effect from the treatment. Data in the literature also indicate that electroshock decreases NEP in the rat brain, as does prolonged swimming in cold water, whereas "insulin stress" allegedly causes no change in the catecholamine content of the brain.

Barchas, J. D., Freedman, D. X.: "Brain amines: response to physiological stress." *Biochem. Pharmacol.* **12**: 1232-1238 (1963).

E29,915/63

In rats, swimming to exhaustion, especially in cold water, caused depletion of brain 5-HT and NEP. Similar changes could not be obtained by having them run in a revolving cage because under the conditions of the experiment the rats soon gave up and just allowed themselves to be dragged. Immersion

of the rats in cold water did reproduce the catecholamine depletion, whereas several other stressors (electroshock, starvation, hypoxia, surgery, adrenalectomy) were inactive in this respect. The effect is not dependent upon the pituitary-adrenocortical system, since active stressors deplete brain catecholamines even after hypophysectomy, as does LSD. It is noteworthy that drugs which induce a similar change in brain amines produce a unique pattern of central excitation, acting on brain mechanisms concerned with metabolic and physiologic temperature regulation. "If the stressors have such a central action, a role for the biogenic amines in central as well as in peripheral aspects of temperature regulation should be sought."

Moore, K. E., Lariviere, E. W.: "Effects of stress and D-amphetamine on rat brain catecholamines." *Biochem. Pharmacol.* **13**: 1098-1100 (1964). G17,075/64

Various stressors increased the toxicity of D-amphetamine, perhaps through the release of NEP. Among the stressors examined (restraint, swimming, electroshock, sound), only some caused a significant increase in amphetamine toxicity and a decrease in brain NEP. In the latter respect, grid-shocked rats were particularly responsive. The depletion of brain NEP by stressors and D-amphetamine might be due to release through excessive stimulation and subsequent destruction at a rate faster than its synthesis. "Dopamine, on the other hand, is not affected by these particular stimuli. This differential depletion of catecholamines in response to various stimuli can perhaps be explained by the fact that they are distributed differently within the brain. Norepinephrine is primarily located in the hypothalamus and other brain stem areas that are believed to represent the central component of the sympathetic nervous system; dopamine is primarily located in the basal ganglia-areas associated with the extrapyramidal system."

Maynert, E. W., Levi, R.: "Stress-induced release of brain norepinephrine and its inhibition by drugs." *J. Pharmacol. Exp. Ther.* **143**: 90-95 (1964). F193/64

In kittens, morphine diminishes the NEP content of the brain stem and the EP store of the adrenal. Both these effects are inhibited by barbiturate anesthesia. Certain stressors (cold, electric shock) likewise decrease brain NEP in rats. Neither brain stem 5-HT nor whole brain acetylcholine is

changed under conditions causing a 40 percent reduction in NEP. After one hour of rest, the NEP is replenished. Sedative doses of chlorpromazine or phenobarbital, unlike strongly depressant amounts of morphine, suppress the release of brain stem NEP in shocked rats. The shock-induced decrease in NEP is also blocked by an MAO inhibitor (Catron).

Levi, R., Maynert, E. W.: "The subcellular localization of brain-stem norepinephrine and 5-hydroxytryptamine in stressed rats." *Biochem. Pharmacol.* **13**: 615-621 (1964).

G11,756/64

Electroshock decreased the total amount of brain stem NEP in unpretreated, but not in phenobarbital-sedated rats; it rose above normal in both shocked and unshocked rats treated with 1-phenyl-2-hydrazinopropane (Catron). The 5-HT concentration was altered only after treatment with Catron. Differential, gradient-density centrifugation of brain stem homogenates showed that NEP and 5-HT have approximately the same localization, about 25 percent being found in the fraction composed almost entirely of nerve ending particles. "It is suggested that in animals treated with sedatives or monoamine oxidase inhibitors the brain-stem NEP, ordinarily released by stress, fails to leave the nerve endings."

Rosecrans, J. A., Feo, J. J. de: "The interrelationships between chronic restraint stress and reserpine sedation." *Arch. Int. Pharmacodyn. Ther.* **157**: 487-497 (1965).

F54,866/65

In rats, stress by restraint initially increased the 5-HT and decreased the NEP content of the brain. "Reserpinized stress animals were more easily handled at first, but became more excitable and difficult to handle as the experiment progressed." This change appeared to correlate with the continued depletion of brain NEP because the brain 5-HT remained approximately constant. The possible protective effect of reserpine is considered in connection with the G.A.S.

Lehmann, A.: "Action de crises répétées d'épilepsie acoustique sur le taux de noradrénaline des zones corticales et sous-corticales du cerveau de souris" (Effects of repeated acoustic epileptic seizures on noradrenaline levels of the cortical and subcortical zones of the brain in mice.) *C.R. Soc. Biol. (Paris)* **159**: 62-64 (1965). F44,990/65

In seizure-susceptible mice, repeated expo-

sure to sound produces eventually fatal convulsive attacks. Mortality is increased by reserpine but is decreased by MAO inhibitors. Audiogenic seizures, especially if they are lethal, greatly diminish the NEP content of the brain, particularly in its subcortical layer. In conjunction with the observation that MAO inhibitors protect, it may be assumed that NEP depletion is the cause of lethality in audiogenic seizures. However, oft-repeated exposure to sound elicits convulsions of diminishing intensity and eventually complete insensitivity ensues. Yet even in these resistant animals, the brain NEP concentration is low. Perhaps lethality depends upon a particularly rapid catecholamine loss.

Akmayev, I. G., Donáth, T.: "Die Katecholamine der Zona palisadica der Eminentia mediana des Hypothalamus bei Adrenalektomie, Hydrocortisonverabreichung und Stress" (Catecholamines in the zona palisadica of the hypothalamic median eminence after adrenalectomy, hydrocortisone administration, and stress). *Z. Mikrosk. Anat. Forsch.* **74**: 83-91 (1965). G37,707/65

In rats, fluorescence microscopy indicates that catecholamines are plentiful in the zona palisadica of the ME. This storage is considerably increased after adrenalectomy and is diminished by cortisol. Presumably, under conditions of enhanced CRF production, the dopamine and NEP content of the nerve terminals rises in this region, whereas blockade of CRF production is associated with an inverse catecholamine response.

Draskoczy, P. R., Lyman, C. P.: "Turnover of catecholamines (CA) during hibernation." *Pharmacologist* **7**: 167 (1965).

J8,151/65

In ground squirrels the turnover rate of labeled NEP and EP during hibernation was greatly reduced in most tissues, particularly in the brain.

Matsui, T., Kobayashi, H.: "Histochemical demonstration of monoamine oxidase in the hypothalamo-hypophysial system of the tree sparrow and the rat." *Z. Zellforsch.* **68**: 172-182 (1965). G35,199/65

In the rat and sparrow the distribution of MAO activity in the ME was essentially similar: "(1) slight or no MAO activity was observed in the ependymal layer, (2) relatively strong activity was revealed in the tissue just beneath the ependymal layer, (3) strong activity was revealed in the outer layer, particularly in the tissues surrounding capillary

loops of the primary plexus. It is suggested that an adrenergic mechanism functions in the median eminence."

Cantril, H., Hunt, W. A.: "Emotional effects produced by the injection of adrenalin." *Am. J. Psychol.* **44**: 300-307 (1966). J13,317/66

Summary of clinical data concerning the various pleasant or unpleasant emotional responses to EP injections in different people.

Bliss, E. L., Zwanziger, J.: "Brain amines and emotional stress." *J. Psychiatr. Res.* **4**: 189-198 (1966). G43,710/66

In guinea pigs, mice and rats in which emotional stress was produced by combat, electric shocks, immobilization, or intracranial stimulation via implanted electrodes, brain NEP decreased in the cortex, subcortex, cerebellum, hypothalamus and brain stem to approximately the same degree. Under these circumstances, the brain concentration of 5-HT, GABA and dopamine remained stable. It appears that decreases of brain NEP may reflect intense emotional distress (22 refs.).

Gordon, R., Spector, S., Sjoerdsma, A., Udenfriend, S.: "Increased synthesis of norepinephrine and epinephrine in the intact rat during exercise and exposure to cold." *J. Pharmacol. Exp. Ther.* **153**: 440-447 (1966).

F70,167/66

In rats, exercise or cold caused little if any change in the NEP content of the brain, heart and spleen. Appreciable decreases were noted only in adrenal EP following severe exercise. However, after treatment with the tyrosine hydroxylase inhibitor α -MT prior to exercise or exposure to cold, NEP and EP levels fell markedly in most tissues, and incorporation of radiotyrosine into the catecholamines was enhanced after exercise. "These findings indicate that the increased sympathetic stimulation, presumably associated with such stressful conditions, induces increased synthesis of norepinephrine levels and epinephrine. The regulatory mechanism most likely operates at the tyrosine hydroxylase step, which is rate-limiting."

Ordy, J. M., Samorajski, T., Schroeder, D.: "Concurrent changes in hypothalamic and cardiac catecholamine levels after anesthetics, tranquilizers and stress in a subhuman primate." *J. Pharmacol. Exp. Ther.* **152**: 445-457 (1966). F67,727/66

In squirrel monkeys, various stressors cause a concurrent depletion of hypothalamic

and cardiac NEP. Pretreatment with chlorpromazine or haloperidol inhibits both these effects.

Euler, U. S. von: "Adrenal medullary secretion and its neural control." In: Martini, L. and Ganong, W. F., *Neuroendocrinology*, Vol. 2, pp. 283-333. New York and London: Academic Press, 1967. E6,914/67

Monograph on the physiology of catecholamines, with special reference to the control of their release by the nervous system, beginning with the "*piqûre diabétique*" of Claude Bernard (nineteenth century) and the work of Karplus and Kreidl (1909). The

importance of the hypothalamus as a center for EP secretion has been the subject of innumerable investigations, especially after accurate quantitative techniques were developed for the measurement of EP and NEP in blood, urine and tissues. The exact determination of the pathways that terminate in the splanchnic nerves that stimulate the secretory activity of the adrenal medulla is complex, because stimulation of widely different parts of the CNS, including the cerebral cortex, hypothalamus and midbrain, can produce catecholamine discharges. Furthermore, stimulation of some regions enhances, while that of others inhibits, catecholamine release, and the central regulation of EP and NEP is selectively influenced by distinct regions, as summarized in Figure 16. Special sections are devoted to the morphology of the adrenal medulla in various species, including subcellular storage particles, chemistry and biosynthesis, and to the principal peripheral

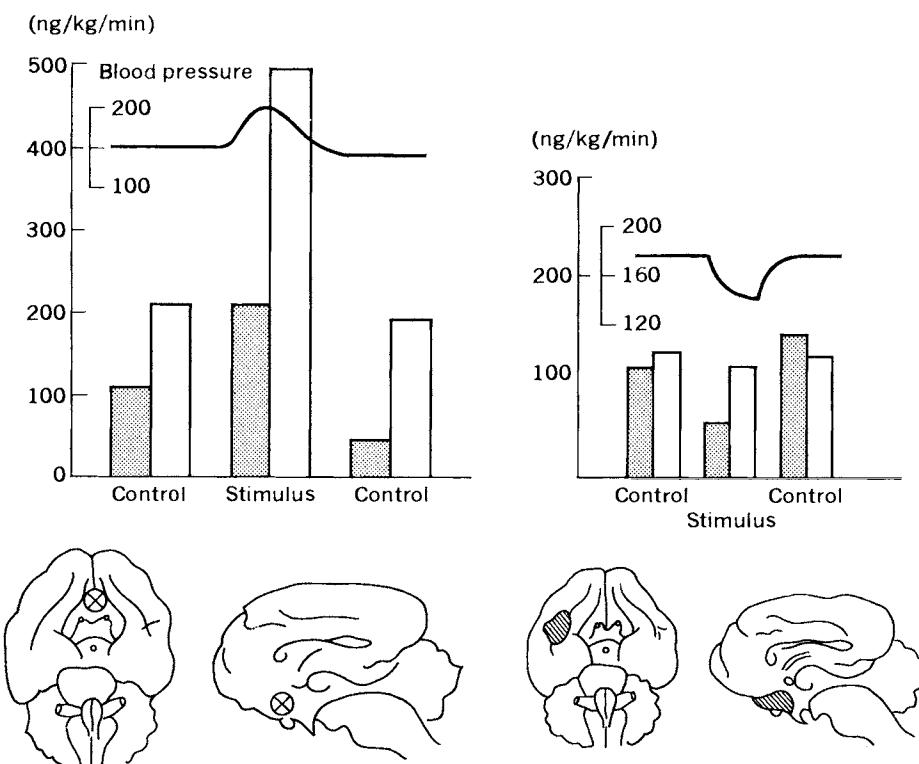

Figure 16. Secretion from left suprarenal gland in the cat before, during and after stimulation of the medial orbital cortex (left) and lateral orbital cortex (right) as indicated on the figure. Darkened columns, epinephrine; plain columns, norepinephrine. (Reproduced from *Neuroendocrinology* 2 (1967) by permission of U. S. von Euler and Academic Press.)

actions of catecholamines when the subject is at rest and during stress (several hundred refs.).

Smelik, P. G.: "ACTH secretion after depletion of hypothalamic monoamines by reserpine implants." *Neuroendocrinology* **2**: 247-254 (1967). F90,175/67

In rats, implantation of reserpine into the hypothalamus reduced the regional 5-HT and catecholamine content. Despite the depletion of hypothalamic monoamines, subsequent systemic treatment with reserpine, chlorpromazine, vasopressin, and emotional or traumatic stress caused the usual hypersecretion of ACTH. Presumably, "under these experimental conditions, there is no indication that monoamines present in the hypothalamus are involved in the control of pituitary ACTH secretion."

Ganong, W. F., Lorenzen, L.: "Brain neurohumors and endocrine function." In: Martini, L. and Ganong, W. F., *Neuroendocrinology*, Vol. 2, pp. 583-640. New York and London: Academic Press, 1967. E6,920/67

Extensive review on neurohormones, particularly catecholamines, 5-HT, acetylcholine, histamine, substance P, γ -aminobutyric acid, and dopamine (about 250 refs.).

Carr, L. A., Moore, K. E.: "Effects of reserpine and α -methyltyrosine on brain catecholamines and the pituitary-adrenal response to stress." *Neuroendocrinology* **3**: 285-302 (1968). H3,332/68

In rats given reserpine (which depletes catecholamine stores) or α -MT (which blocks catecholamine synthesis), the brain content of NEP and dopamine was markedly reduced, but plasma corticosterone levels were essentially unchanged at rest as well as after treatment with stressors (ether, histamine, formalin, restraint, changes in environment). "The results suggest that brain catecholamines do not play an essential role in stress-induced activation of the pituitary-adrenal system."

Welch, B. L., Welch, A. S.: "Differential activation by restraint stress of a mechanism to conserve brain catecholamines and serotonin in mice differing in excitability." *Nature* **218**: 575-577 (1968). F98,490/68

Bliss, E. L., Ailion, J., Zwanziger, J.: "Metabolism of norepinephrine, serotonin and dopamine in rat brain with stress." *J. Pharmacol. Exp. Ther.* **164**: 122-134 (1968). H4,230/68

"The stress of foot shock in rats induces large decreases in the level of brain norepinephrine but does not greatly alter the concentration of serotonin or dopamine in brain."

Thierry, A.-M., Javoy, F., Glowinski, J., Kety, S. S.: "Effects of stress on the metabolism of norepinephrine, dopamine and serotonin in the central nervous system of the rat. I. Modifications of norepinephrine turnover." *J. Pharmacol. Exp. Ther.* **163**: 163-171 (1968). H2,261/68

By use of radioactive NEP, 5-HT and dopamine, it was found that stress (electroshock) did not significantly influence the endogenous level of NEP but markedly raised its turnover in NEP-containing neurons of the brain stem-mesencephalon and spinal cord. "This stress increased the synthesis of 5HT in the brainstem-mesencephalon as seen by the greater increase of endogenous 5HT after monoamine oxidase inhibition but did not affect the disappearance of intracisternally administered H³-5HT. Changes in NE turnover regulation induced by electric foot shocks were studied in various conditions. There was an enhanced turnover of NE in the brainstem-mesencephalon when higher intensities of stimulation were used; this was associated with an increased accumulation of H³-normetanephrine; no modification was seen when the frequency of stimulation was increased. NE turnover during an acute stress session was enhanced to a greater degree when rats were previously subjected to many stress sessions. The initial accumulation of H³-NE in the brainstem-mesencephalon was decreased just after an acute stress and increased 24 hr after the last electric shock stress session of a chronic stress treatment."

Scapagnini, U., Preziosi, P., Schaefferdryver, A. de: "Influence of restraint stress, corticosterone and betamethasone on brain amine levels." *Pharmacol. Res. Commun.* **1**: 63-69 (1969). G80,096/69

In rats, the changes in brain 5-HT, dopamine and NEP provoked by restraint do not

seem to result from the negative feedback effect of endogenous corticosterone.

Bliss, E. L., Ailion, J.: "Response of neurogenic amines to aggregation and strangers." *J. Pharmacol. Exp. Ther.* **168**: 258-263 (1969).

H15,845/69

Aggregation of mice unaccustomed to each other caused a decrease in brain NEP and an acceleration of its catabolism. 5-HT levels remained unchanged, although 5-HIAA concentrations in the brain rose, indicating an increased catabolism of 5-HT. "Dopamine levels in brain and its catabolism were unaffected. At the same time no changes in norepinephrine metabolism could be detected in the adrenal, heart or spleen. The intermingling of strangers without aggregation also decreased brain norepinephrine. A more severe stress of footshock to rats not only diminished brain norepinephrine but also radically reduced catecholamine levels in the adrenal and spleen. These observations suggest that emotional disturbances activate the norepinephrine and serotonin systems in brain."

Rosecrans, J. A.: "Brain amine changes in stressed and normal rats pretreated with various drugs." *Arch. Int. Pharmacodyn. Ther.* **180**: 460-470 (1969).

H18,475/69

In rats exposed to the stressor effect of vibration, 5-HT and NEP concentrations were determined in various areas of the brain. Apparently, NEP neurons were stimulated while the 5-HT systems were depressed. The latter, however, "were activated if this amine was depleted prior to stress, indicating the presence of a 5-HT negative feedback system. Lastly, there were differences observed in brain area responsiveness to stress, indicating the existence of different neuronal populations in the areas studied."

H28,002/69

Microelectrophoresis allows deposition of minute amounts of soluble compounds in the immediate extracellular environment of single cells in the CNS and permits direct monitoring of the local response by recording single unit action potentials. In rats, it has been shown with this technique that dexamethasone-sensitive cells can be identified accurately and localized in the hypothalamus and midbrain, scattered over wide areas. The large majority of these cells are clearly inhibited, but some are activated. No steroid-sensitive neurons were found in the cortex, dorsal hypothalamus or thalamus. The steroid-sensitive neurons were responsive to microelectrophoretically applied NEP and acetylcholine. The predominant action of the former was inhibition, that of the latter was stimulation. ACTH activated the steroid-sensitive neurons. Presumably, "specific nerve cells in the hypothalamus and midbrain are sensitive to both hormonal and humoral factors and involved in negative and positive feedback actions of the hormones."

Schaepdryver, A. de, Preziosi, P., Scapagnini, U.: "Brain monoamines and adrenocortical activation." *Br. J. Pharmacol.* **35**: 460-467 (1969).

G65,782/69

No strict correlation was found between depletion of brain monoamine stores by various drugs and corticoid secretion in rats. Restraint increased brain 5-HT and greatly stimulated corticosterone discharge. "Brain amine content does not seem to play an important part in the control of corticotrophin releasing factor in corticotrophin secretion by the pituitary gland. The relationship between hypothalamic monamines and other neurohumours is discussed."

Glowinski, J.: "Metabolism of catecholamines in the central nervous system and correlation with hypothalamic functions." In: Martini, L., Motta, M. et al., *The Hypothalamus*, pp. 139-152. New York and London: Academic Press, 1970.

J12,266/70

Within a review on catecholamine metabolism in the CNS, a small section is devoted to the literature, which suggests that noradrenergic and serotonergic neurons may

play a role in stress, especially in connection with the release of ACTH.

Stone, E. A.: "Behavioral and neurochemical effects of acute swim stress are due to hypothermia." *Life Sci. [I]* **9**: 877-888 (1970). G77,276/70

In rats, forced swimming at 15°C causes hypothermia, inactivity and reduction of brain NEP. These changes can be prevented by rapid rewarming or by swimming in 37°C water.

Reserpine pretreatment increases the mortality of rats exposed to the stress of restraint, presumably because of its central rather than peripheral NEP-depleting action.

Thierry, A.-M., Blanc, G., Glowinski, J.: "Preferential utilization of newly synthesized norepinephrine in the brain stem of stressed rats." *Eur. J. Pharmacol.* **10**: 139-142 (1970). H24,015/70

Thierry, A.-M., Blanc, G., Glowinski, J.: "Effect of stress on the disposition of catecholamines localized in various intraneuronal storage forms in the brain stem of the rat." *J. Neurochem.* **18**: 449-461 (1971). G82,745/71

Corrodi, H., Fuxe, K., Lidbrink, P., Olson, L.: "Minor tranquilizers, stress and central catecholamine neurons." *Brain Res.* **29**: 1-16 (1971). G85,849/71

Chlordiazepoxide, diazepam and nitrazepam blocked the stress-induced stimulation of NEP neurons by decreasing their nervous activity. Chlordiazepoxide and diazepam potentiated the stress (restraint)-induced fall in nervous activity in ascending dopaminergic neurons. Stress combined with these drugs therefore decreased dopamine turnover in the telencephalon in comparison with normal rats (67 refs.).

Brief abstract of experiments with dopa, α -MT, guanethidine and FLA-63 that induced alterations in hypothalamic NEP, supporting the idea of a central adrenergic mechanism inhibiting ACTH secretion, and suggesting that NEP rather than dopamine is responsible for such "tonic inhibition."

Loon, G. R. van, Scapagnini, U., Moberg, G. P., Ganong, W. F.: "Evidence for central adrenergic neural inhibition of ACTH secretion in the rat." *Endocrinology* **89**: 1464-1469 (1971). H49,479/71

"A significant negative correlation was found between plasma corticosterone and hypothalamic contents of norepinephrine and dopamine after administration of α -MT and L-dopa. The administration into the third ventricle of the brain of a systemically ineffective dose of α -MT increased plasma corticosterone 9 hr. later. These data support our hypothesis of central adrenergic neural inhibition of ACTH secretion in rats."

Loon, G. R. van, Hilger, L., King, A. B., Boryczka, A. T., Ganong, W. F.: "Inhibitory effect of L-dihydroxyphenylalanine on the adrenal venous 17-hydroxycorticosteroid response to surgical stress in dogs." *Endocrinology* **88**: 1404-1414 (1971). H39,650/71

In dogs the adrenal venous 17-OHCS elevation after surgical stress was suppressed by L-dopa but not by NEP or intravenous dopamine. "The minimum effective dose of L-dopa that inhibited the 17-OHCS response to stress was decreased by the monoamine oxidase inhibitor, pargyline, and increased by the catecholamine synthesis inhibitor, α -methyl-p-tyrosine. These data support the hypothesis of a central adrenergic neural system which inhibits ACTH secretion in dogs" (42 refs.).

Stone, E. A.: "Hypothalamic norepineph-

rine after acute stress." *Brain. Res.* **35**: 260-263 (1971). H65,343/71

Loon, G. R. van, Scapagnini, U., Cohen, R., Ganong, W. F.: "Effect of intraventricular administration of adrenergic drugs on the adrenal venous 17-hydroxycorticosteroid response to surgical stress in the dog." *Neuroendocrinology* **8**: 257-272 (1971).

H48,631/71

In dogs, intraventricular administration of several adrenergic drugs suppresses 17-OHCS secretion in response to laparotomy. The same is true of the catecholamine precursor L-dopa and the MAO inhibitor α -ethyltryptamine. On the other hand, tyramine (which releases catecholamines from nerve endings) blocks the 17-OHCS response when given intraventricularly, but not when given systemically. "These data support our previously presented hypothesis that a central adrenergic neural system inhibits ACTH secretion in dogs."

Forced motility in a treadmill enhances 5-HT metabolism in the rat forebrain within one hour; this is followed by an increase in the brain stem, especially the mesencephalon-pons-medulla regions. The changes almost disappear after fifty minutes of rest. NEP metabolism is also increased under similar conditions in the rat brain stem.

Ohara, K., Isobe, Y., Sato, H.: "Heat tolerance and catecholamine content in the hypothalamus of the rat." *J. Physiol. Soc. Jap.* **34**: 549-550 (1972). H79,325/72

In rats, exposure to heat caused an initial elevation of NEP with a decrease in dopamine in the hypothalamus, interpreted as "an alarm reaction against heat stress," presumably necessary for adaptation to high ambient temperatures.

Scapagnini, U., Preziosi, P.: "Role of brain norepinephrine and serotonin in the

tonic and phasic regulation of hypothalamic hypophyseal adrenal axis." *Arch. Int. Pharmacodyn. Ther.* **196** Supp: 205-220 (1972). H56,654/72

Résumé of the literature and the extensive experiments of the authors and their co-workers led to the following main conclusions: (1) there is an adrenergic system in the brain that inhibits ACTH secretion. Drugs that release active catecholamines from nerve endings block ACTH discharge if they can pass the blood-brain barrier or are injected directly into the third ventricle or ME. Stressors deplete brain NEP and increase ACTH secretion. Admittedly, the amount of drugs necessary for inhibition is large compared to the normal catecholamine levels present in the brain, and hence their action is of doubtful physiologic significance. They may act merely by constricting the portal vessels so that CRF cannot reach an adequate concentration in the adenohypophysis. Among the drugs used to explore the ACTH inhibitory adrenergic mechanism were: amphetamine, α -ethyltryptamine, L-dopa, tyramine, α -MT, guanethidine, FLA-63 (an inhibitor of dopamine- β -oxidase), L-threo-dihydroxy-phenyl-serine (DOPS), which selectively repletes NEP after depletion of NEP and dopamine by α -MT, phentolamine (an α -blocking agent) and so on. (2) 5-HT appears to regulate the circadian variations of ACTH secretion by the limbic system. Its concentration is especially large in the raphé nuclei (containing the highest level of serotonergic cell bodies), particularly the amygdala and hippocampus, in which it shows circadian variations. Destruction of these nuclei abolishes the circadian plasma corticosterone rhythm.

Ganong, W. F.: "Evidence for a central noradrenergic system that inhibits ACTH secretion." In: Knigge, K. M., Scott, D. E. et al., *Brain-Endocrine Interaction. Median Eminence: Structure and Function*, pp. 254-266. Basel and New York: S Karger, 1972.

E10,568/72

Observations in the dog and rat suggest the existence of a central noradrenergic system that inhibits ACTH secretion. There is NEP, as well as dopamine, in the ME. The NEP-containing neurons probably originate outside the ventral hypothalamus, since deafferentation of the latter causes virtual disappearance of NEP from the island. Dopamine- and NEP-containing neurons end near or on the portal vessels, and hence they could

enter the portal blood and act directly on the pituitary affecting ACTH secretion.

G95,413/72

Bendikov, É. A., Basaeva, A. I.: "The use of DOPA in replacement therapy in disturbances of circulatory regulation during stress." *Biull. Éksp. Biol. Med.* **76** No. 12: 36-39 (1973). Engl. trans.: *Bull. Exp. Biol. Med.* **76**: 1414-1416 (1973). J20,146/73

In cats, stress produced by injection of potassium chloride into the lateral ventricles caused depletion of NEP in the hypothalamus, with inhibition of sympathetic vaso-motor tone. These changes could be corrected by injection of DOPA.

Lee, C.-H., Morita, A., Saito, H., Takagi, K.: "Changes in catecholamine levels of mouse brain during oscillation-stress." *Chem. Pharm. Bull. (Tokyo)* **21**: 2768-2770 (1973). J24,138/73

In mice subjected to vibration for two hours, the NEP levels of the brain decreased considerably. These observations are in disagreement with earlier findings, according to which stress decreases the level of brain NEP unless resynthesis is simultaneously blocked.

Korf, J., Aghajanian, G. K., Roth, R. H.: "Increased turnover of norepinephrine in the rat cerebral cortex during stress: role of the locus coeruleus." *Neuropharmacology* **12**: 933-938 (1973). J21,582/73

"The noradrenergic nerve terminals in the rat cerebral cortex are mainly supplied by norepinephrine-containing neurones originating in the locus coeruleus." Stress increases the turnover of NEP in this location. Apparently, "the locus coeruleus plays an important role in mediating the effect of stress on the metabolism of norepinephrine in the cerebral cortex."

Smith, A. D.: "Mechanisms involved in the release of noradrenaline from sympathetic nerves." *Br. Med. Bull.* **29**: 123-129 (1973). J2,975/73

Review of the mechanisms responsible for

NEP release from sympathetic nerve endings in vivo and in vitro, with special reference to the underlying biochemical and ultrastructural phenomena. The possible events during stimulus-secretion coupling are summarized in Figure 17 (p. 1072), a diagram of the life history of noradrenergic vesicles (based on Figure 15 of Smith & Winkler, 1972).

Pletscher, A., Prada, M. da, Steffen, H., Berneis, K. H., Lütold, B.: "Evidence of two mechanisms for the storage of catecholamines in adrenal chromaffin granules." *Life Sci.* **13**: cxxix-cxxx (1973). J6,310/73

Observations on isolated membranes of bovine chromaffin granules revealed two mechanisms of catecholamine storage. "At the level of the granular membrane the amines are pumped into the organelles by an ATP/Mg⁺⁺-dependent process. Within the organelles, the amines interact with ATP and possibly chromogranins, whereby the diffusion of the amines out of the granules is reduced. This enables the amine pump to maintain the very high concentration gradient found in vivo. On the other hand, the loose bonding of the intragranular amines warrants the reversibility of the storage process enabling the amines to be rapidly liberated, e.g. during the release process."

Kvetnansky, R.: "Neural and endocrine regulation of adrenal catecholamine biosynthesis in stress." In: Németh, Š., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 55-66. Bratislava: Slovak Academy of Sciences, 1973. E10,457/73

In rats adapted to the stress of restraint, adrenal medullary enzymatic biosynthesis of catecholamines was increased under the influence both of corticoids and nervous stimulation (12 refs.).

Detailed description of four mechanisms of neuronal and extraneuronal catecholamine uptake which affect the metabolism, inactivation and pharmacologic actions of these substances.

Anokhina, I. P., Zabrodin, G. D., Svirino-

**KEY:**

L: primary lysosome; LV: large noradrenergic vesicle; MT: microtubule; MVB: multivesicular body; N: nucleus; RER: rough endoplasmic reticulum; SER: smooth endoplasmic reticulum; SV: small noradrenergic vesicle

- 1: large noradrenergic vesicles originate from the Golgi apparatus
- 2: large vesicles are transported along the axon by a process involving microtubules
- 3: large vesicles secrete proteins and NA by exocytosis
- 4: membrane of large vesicle is converted into small coated pits
- 5: coated pits bud from plasma membrane to give coated vesicles which become electron-lucent small vesicles
- 6: electron-lucent small vesicles take up or synthesize NA and become small noradrenergic vesicles
- 7: alternative possible modes of formation of small vesicles—either by budding from SER or by fission of intact large vesicle
- 8: small vesicles release their content either by exocytosis or by forming a tight junction with plasma membrane
- 9: empty small vesicles are re-charged with NA
- 10: empty small vesicles are ultimately digested in multivesicular bodies

Figure 17. Possible events in the life-history of noradrenergic vesicles (based on Fig. 15 of Smith and Winkler, 1972). (Reproduced from *Brit. Med. Bull.* 29 (1973) by permission.)

vskii, I. E.: "Neurochemical mechanisms of formation of psychopathologic conditions due to emotional stress." *Zh. Nevropatol. Psichiatr.* 73 No. 12: 1825-1833 (1973) (Russian). J16,960/73

Studies on changes in catecholamine and 5-HT metabolism in various brain areas of rats exposed to different stressors.

Johansson, G., Frankenhaeuser, M.: "Temporal factors in sympato-adrenomedullary activity following acute behavioral activation." *Biol. Psychol.* 1: 63-73 (1973). J11,366/73

In healthy young males subjected to complex choice-reaction tasks, the mean EP output during arousal increased but showed considerable individual variations in intensity and duration. "When subjects whose adrenaline output decreased rapidly were com-

pared with those whose adrenaline output decreased slowly, it was found that 'rapid decreasers' had higher baseline levels of adrenaline, performed better on the choice-reaction task, and had lower scores in neuroticism. The significance of temporal factors in adrenaline-mediated adjustment to environmental stressors is discussed."

Prasad, G. C., Siddiqui, M. Z., Udupa, K. N.: "Autoradiographic studies on the role of adrenaline in stress by using H³ adrenaline." *Am. J. Roentgenol.* 118: 852-860 (1973). J5,383/73

By use of labeled EP in rats submitted to the stress of bone fractures, it was possible to "localize the particular cells in the hypothalamus (PVN) which could be responsible for the endocrine and metabolic changes in the body after stress. The radioactive adrenaline

granules could be seen in the various tissues at different intervals, including the thyroid gland, adrenal gland, heart muscle, liver, kidney, etc., suggesting the site of action of adrenaline on these tissues at different periods."

Endrőczi, E., Tallian, F.: "Catecholaminergic control of pituitary function." In: Németh, S., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 15-24. Bratislava: Slovak Academy of Sciences, 1973. E10,454/73

In rats, ovariectomy decreases hypothalamic catecholamines, and these can be restored by intrahypothalamic injections of estradiol. Bilateral preoptic lesions also decrease hypothalamic catecholamine concentrations, but this effect cannot be counteracted by estradiol. Hypothalamic catecholamines are raised in lactating rats and by implantation of LTH into the ME.

Scapagnini, U., Annunziato, L., Preziosi, P.: "Role of brain norepinephrine in stress regulation." In: Németh, S., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 25-36. Bratislava: Slovak Academy of Sciences, 1973. E10,455/73

Review of the literature and personal observations in dogs which partly clarified but did not resolve the problem of whether cerebral NEP as a "transmitter is just a tonic inhibitor that has to be removed in order to activate the system, or is additionally involved in the feedback regulation that follows plasmatic corticosteroid increase" (25 refs.).

Glowinski, J.: "Some characteristics of the 'functional' and 'main storage' compartments in central catecholaminergic neurons." *Brain Res.* **62**: 489-493 (1973). J8,854/73

The author postulates a two-compartment model of catecholamine storage in central nerve endings: one a "functional," the other a "main storage" pool. Isotope studies on rat brains indicate enhanced utilization of NEP in the "main storage" compartment "in a variety of circumstances such as intense stress, repeated electroshock sessions, deprivation of paradoxical sleep, adrenalectomy" (21 refs.).

Fahringer, E. E., Foley, E. L., Redgate, E. S.: "Pituitary adrenal response to ketamine and the inhibition of the response by catecholaminergic blockade." *Neuroendocrinology* **14**: 151-164 (1974). H86,423/74

When given intraperitoneally, ketamine, a

centrally acting nonbarbiturate anesthetic, caused a rise in the corticosterone content of rat plasma which was abolished by hypophysectomy or dexamethasone. This response was not much altered by pretreatment with atropine or phentolamine but was significantly diminished by propranolol or haloperidol. The authors assume that the "response to ketamine is mediated through a facilitatory α -adrenergic and/or dopaminergic pathway or some hybrid thereof, and that ketamine is a convenient and useful agent for testing pituitary adrenal responsiveness in the rat."

Wied, D. de, Jong, W. de: "Drug effects and hypothalamic-anterior pituitary function." *Annu. Rev. Pharmacol.* **14**: 389-412 (1974). J12,125/74

Review of the literature on the effect of various drugs upon the secretion of adenohypophyseal hormones suggests that monoamines control the discharge of many releasing factors from the ME. The neuroendocrine transducer cells differ from neurons as well as from endocrine cells in that they convert neuronal input to humoral output (206 refs.).

Ellison, G. D., Bresler, D. E.: "Tests of emotional behavior in rats following depletion of norepinephrine, of serotonin, or of both." *Psychopharmacologia* **34**: 275-288 (1974). J9,987/74

Schildkraut, J. J.: "Biogenic amines and affective disorders." *Annu. Rev. Med.* **25**: 333-348 (1974). J12,641/74

Review of the literature and personal observations indicate that "different subgroups of patients with depressive disorders may exhibit different specific abnormalities in the metabolism of norepinephrine or other biogenic amines," particularly dopamine and 5-HT. The relationship between stress and metabolic changes in these substances is considered, but not regarded as proven (119 refs.).

Abe, K., Hiroshige, T.: "Changes in plasma corticosterone and hypothalamic CRF levels following intraventricular injection or drug-induced changes of brain biogenic amines in the rat." *Neuroendocrinology* **14**: 195-211 (1974). H86,427/74

In rats, "brain amines were depleted by pretreatment with either reserpine or 6-hydroxydopamine. In spite of the persistence of marked depletion of hypothalamic NEP content, the basal circadian rhythm as well as stress-induced changes in both plasma corticosterone and hypothalamic CRF levels

were preserved in almost the normal fashion. In addition, more than two-fold increases of brain amine concentration by pretreatment with a MAO inhibitor affected neither basal circadian rhythm nor a stress-induced increase in the plasma corticosterone. These observations suggest strongly that brain amines are of relatively little importance in the central regulation of ACTH secretion in the rat." NEP, dopamine, carbachol and GABA were injected into the lateral ventricles, and in large doses all of them except GABA elicited a significant increase in ACTH release.

Costa, E., Meek, J. L.: "Regulation of biosynthesis of catecholamines and serotonin in the CNS." *Annu. Rev. Pharmacol.* **14**: 491-511 (1974). J12,127/74

Review of catecholamine and 5-HT synthesis in the nervous system under various conditions including stress. Benzodiazepines (minor tranquilizers) block the increase in NEP turnover produced by stress, in doses devoid of any such effect at rest. They might directly affect a system of neurons that, in stress, influence noradrenergic neurons (161 refs.).

Hoeldtke, R.: "Catecholamine metabolism in health and disease." *Metabolism* **23**: 663-686 (1974). H87,374/74

Review of catecholamine metabolism in health, during stress and under the influence of various diseases which specifically alter it (216 refs.).

Koob, G. F., Annau, Z.: "Behavioral and neurochemical alterations induced by hypoxia in rats." *Am. J. Physiol.* **227**: 73-78 (1974). H89,535/74

In rats, hypoxia caused a decrease in the NEP content, but no change in the 5-HT concentration, of the forebrain. In rats with electrodes implanted into the lateral hypothalamus, "self-stimulation rates increased while food and water intake decreased during the first 12 h and subsequently returned toward control levels.... The results suggest a time-related activation of central adrenergic neuronal systems during exposure to hypoxia." The observation of a differential effect of hypoxia on NEP and 5-HT agrees with several earlier studies using other stressors (36 refs.).

Kumeda, H., Uchimura, H., Kawabata, T., Maeda, Y., Okamoto, O., Kawa, A., Kane-

his, T.: "Role of brain noradrenaline in the regulation of pituitary-adrenocortical functions." *J. Endocrinol.* **62**: 161-162 (1974). H90,058/74

In rats, intraventricular injections of 6-hydroxydopamine (which does not cross the blood-brain barrier) caused lasting depletion of brain catecholamines without affecting 5-HT or peripheral NEP. Fourteen days later the NEP content of the hypothalamus and brain stem decreased by about 30 percent, and no appreciable amount of NEP was detectable in the cortex or midbrain. This depletion did not influence plasma or adrenal corticosterone, nor did it prevent increased corticosterone secretion after exposure to stressors (sound, restraint, ether, vasopressin) or suppression of corticoid production by dexamethasone. It is concluded that NEP is not involved in regulating pituitary-adrenocortical activity at rest, during stress or during feedback inhibition.

Modigh, K.: "Effects of social stress on the turnover of brain catecholamines and 5-hydroxytryptamine in mice." *Acta Pharmacol. Toxicol. (Kbh.)* **34**: 97-105 (1974). J16,345/74

Male mice, at first isolated, then brought together, immediately start to fight, and exhibit characteristic changes in the turnover of brain catecholamines and 5-HT.

Cuello, A. C., Shoemaker, W. J., Ganong, W. F.: "Effect of 6-hydroxydopamine on hypothalamic norepinephrine and dopamine content, ultrastructure of the median eminence, and plasma corticosterone." *Brain Res.* **78**: 57-69 (1974). J15,544/74

In rats, injection of 6-hydroxydopamine intraperitoneally or into the third ventricle reduced hypothalamic NEP and elevated plasma corticosterone, suggesting increased ACTH secretion. There were degenerative changes in a few neurons ending in the external layer of the ME, while other neurons in the same region remained unaffected. Hypothalamic NEP and plasma corticosterone returned to normal fifteen days after the intraperitoneal injection, whereas this was not yet the case after intraventricular administration of the drug. In both groups, neuronal debris accumulated in the phagocytes, but most neurons remained normal. Presumably, NEP-containing neurons end in the external layer of the ME, and the central adrenergic system inhibits ACTH secretion. After fifteen days, a yet unknown mechanism compensates

for the decrease in NEP, and ACTH release returns to normal.

Palkovits, M., Brownstein, M., Saavedra, J. M., Axelrod, J.: "Norepinephrine and dopamine content of hypothalamic nuclei of the rat." *Brain Res.* **77**: 137-149 (1974).

J15,433/74

In rats, various hypothalamic nuclei contain three to twenty times more NEP and dopamine than does the cerebral cortex. The nuclei are very uneven as regards their amine content, but the ME is among the regions richest in dopamine and has only about half as much NEP. "All of the hypothalamic nuclei contain dopamine. It is highly concentrated in the rostral subdivisions of the arcuate nucleus, the paraventricular and dorsomedial nuclei, the retrochiasmatic area, the medial posterior subdivision of the ventromedial nucleus and in the medial forebrain bundle at the posterior hypothalamic level. The highest concentrations of norepinephrine were found in the paraventricular and dorsomedial nuclei and in the retrochiasmatic area. The rostral subdivisions of the arcuate nucleus and the periventricular and preoptic suprachiasmatic nuclei are also rich in norepinephrine" (29 refs.).

Brown, R. M., Snider, S. R., Carlsson, A.: Changes in biogenic amine synthesis and turnover induced by hypoxia and/or foot shock stress. II. The central nervous system." *J. Neural Transm.* **35**: 293-305 (1974).

J25,021/74

Ögren, S. O., Fuxe, K.: "Learning, brain noradrenaline and the pituitary-adrenal axis." *Med. Biol.* **52**: 399-405 (1974).

J24,846/74

In rats, the NEP pathways to the forebrain were destroyed by the injection of 6-hydroxydopamine (6-OH-DA) into the coeruleo-cortico (dorsal) bundle without significantly impairing retention of the conditioned avoidance response (CAR). However, when 6-OH-DA lesions were combined with adrenalectomy, "there was a marked reduction of the retention of CAR and a complete failure to relearn the CAR."

Johansson, G.: "Relation of biogenic

amines to aggressive behaviour." *Med. Biol.* **52**: 189-192 (1974) (33 refs.).

J17,685/74

Annunziato, L., Renzo, G. F. di, Lombardi, G., Preziosi, P., Scapagnini, U.: "Catecholaminergic control of thyroid stimulating hormone (TSH) and adrenocorticotropic hormone (ACTH) secretion." *Br. J. Pharmacol.* **52**: 442P-443P (1974). H97,357/74

Pretreatment of rats with α -MT significantly enhanced ACTH secretion, both under normal conditions and upon exposure to cold. Concurrent administration of DOPA reduced this effect in normal animals. TTH release was diminished by α -MT only in cold-stressed rats. The results are considered as being compatible with the concept that catecholamines influence ACTH and TTH secretion in opposite ways.

Stern, W. C., Morgane, P. J., Miller, M., Resnick, O.: "Protein malnutrition in rats: response of brain amines and behavior to foot shock stress." *Exp. Neurol.* **47**: 56-67 (1975).

J23,635/75

"Regional brain levels of the amines and 5-hydroxyindoleacetic acid showed little change in normal rats following up to 90 min. of shock, whereas depletions of up to 50% occurred in chronically protein malnourished rats. These neurochemical changes in the chronically malnourished rats were pronounced in the diencephalon and in the mid-brain-pons-medulla brain regions. Normal rats which were switched in adulthood to the low protein diet showed minimal decreases in brain amine and 5-hydroxyindoleacetic acid levels following foot shock. This suggests that the effects observed in the chronically malnourished rats reflect a developmental interaction and were not due to the diet being administered at the time of testing" (25 refs.).

Frohman, L. A., Stachura, M. E.: "Neuropharmacologic control of neuroendocrine function in man." *Metabolism* **24**: 211-234 (1975) (160 refs.).

H98,919/75

A review of the literature on neuroendocrine function in general leads to the suggestion that hypophyseal function may be regulated by the hypothalamus as summarized in Figure 18 (p. 1076).

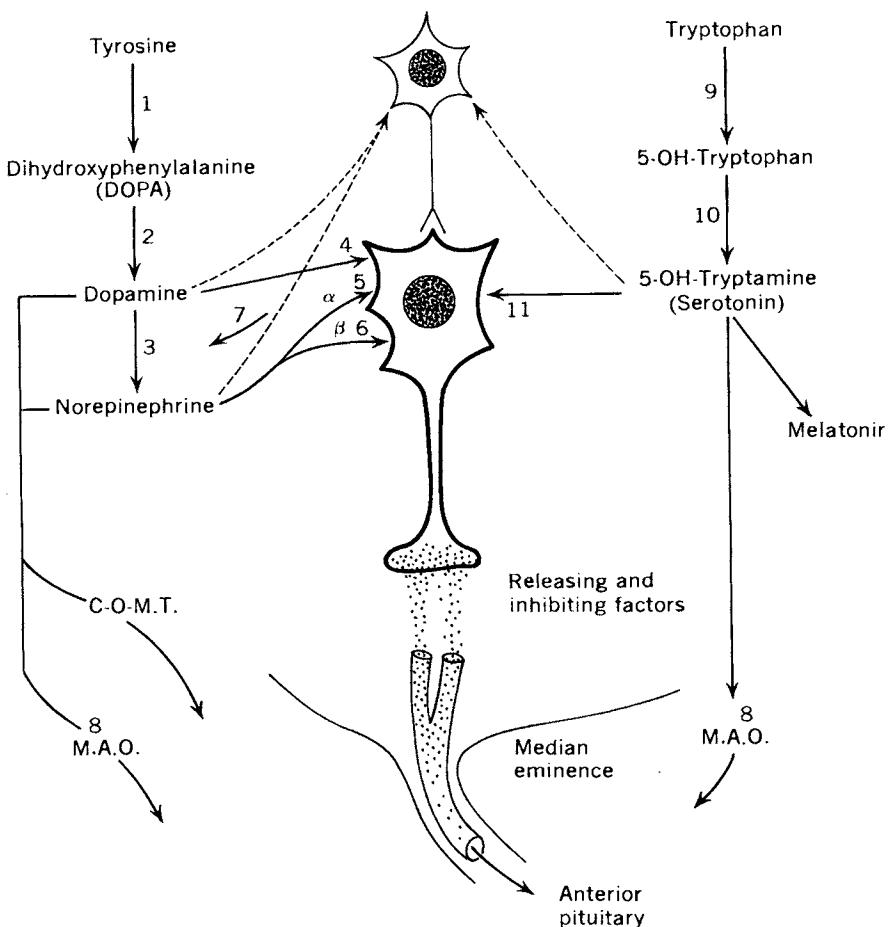

Figure 18. Schematic representation of potential monoamine relationships to the hormone-secreting neurons of the hypothalamus. The numbers refer to enzymatic steps or to sites of possible neuropharmacologic effect. (Reproduced from *Metabolism* 24 (1975) by permission of L. A. Frohman and M. E. Stachura, and Grune & Stratton.)

Dopamine

Many of the data concerning the possible role of dopamine in the regulation of stress reactions have been discussed in the sections on EP, NEP and 5-HT, since changes in these compounds were often studied comparatively, and it would be unnecessarily repetitious to describe them separately under each of these headings.

It should be pointed out here, however, that according to most investigators, NEP rather than dopamine is the principal tonic inhibitor of corticosterone secretion, although—as we will see—5-HT also may play a role in the neural control of the pituitary-adrenal axis.

Fluorescent microscopic studies showed noradrenergic but not dopaminergic fibers in the subependymal layer of the ME in the dog.

In man, dopa has been said to increase STH secretion by stimulating the discharge

of STH-RF (STH-releasing factor), but acromegalics may exhibit an inverse response. The dopaminergic control of STH secretion is allegedly under the influence of the diencephalon in man.

Dopamine

Fluorescence studies on the neurohypophysis of the rat to determine NEP and dopamine levels within terminal sympathetic nerve fibers. "In acute stress the noradrenalin and the dopamine content seems to be increased in the terminal sympathetic nerve fibers. Catecholamine content in the sympathetic nerve fiber terminals of the pars posterior of the neurohypophysis and its increase in acute stress are discussed in connection with the transport of the neurosecretion hormonally-active substances into the blood circulation."

Goldberg, M. E., Salama, A. I.: "Relationship of brain dopamine to stress-induced changes in seizure susceptibility." *Eur. J. Pharmacol.* **10**: 333-338 (1970).

H26,394/70

"Mice stressed in a revolving drum exhibited a biphasic increase in the latency to tonic extension following maximal electroshock. The prolonged increase in seizure latency was paralleled by an increase in brain dopamine levels." These changes were prevented by α -MT, given before the stressor. No alterations in brain NEP or 5-HT were noted. These and other observations suggest

that "stress may possibly result in decreased utilization of dopamine in the brain."

In cats, stress produced by injection of potassium chloride into the lateral ventricles caused depletion of NEP in the hypothalamus, with inhibition of sympathetic vaso-motor tone. These changes could be corrected by injection of DOPA.

Collu, R., Jéquier, J. C., Letarte, J., Leboeuf, F., Ducharme, J. R.: "Effect of stress and hypothalamic deafferentation on the secretion of growth hormone in the rat." *Neuroendocrinology* **11**: 183-190 (1973).

H68,127/73

Ether and auditory stressors were equally effective in diminishing plasma STH (radioimmunoassay) in controls and frontally deafferented rats. Ether also inhibited STH secretion in completely deafferented animals,

whereas auditory stress was ineffective. α -MT pretreatment blocked the effect of ether after complete deafferentation. These and other data "seem to indicate that ether stress is transmitted through a humoral, dopaminergic pathway, while auditory stress follows a nervous pathway." [The many observations suggesting increased STH secretion during stress are not discussed (H.S.).]

Corticoids

The crucial part played by glucocorticoids in stress reactions has been discussed in so many connections throughout this volume, as well as in our earlier stress monographs, that we need not recapitulate all the pertinent data here.

Briefly, glucocorticoid secretion depends entirely, or almost entirely, upon the direct effect of ACTH on the cortical cells; it can be demonstrated even by adding ACTH to adrenocortical slices in tissue culture. It may be mentioned that, although negligible in practice, some residual glucocorticoid secretion apparently does occur even in the absence of the pituitary, perhaps owing to stimulation by some extrahypophyseal ACTH-like principle and/or adenohypophyseal cells in the pars tuberalis. In many species such as the rat, this body remains attached to the ME after hypophysectomy performed by a conventional technique.

The principal role of the glucocorticoids is to increase stress resistance in general, to inhibit inflammation and various types of immune reactions, and to cause thymic-lymphatic atrophy, lymphopenia, eosinopenia and gluconeogenesis.

The active fraction of the excess corticoids circulates in the blood in free form, but it can be inactivated by chemical degradation or by binding to transcortin and certain other plasma proteins, as well as by excretion in urine and sweat. Sweat contains a significant fraction of the total amount of excreted corticoids, but because of technical difficulties it has not been subjected to as careful an analysis as the blood and urinary elimination products.

Much less is known about the mechanism regulating mineralocorticoid secretion. In hypophysectomized dogs, ACTH increased not only cortisol but also aldosterone production. Complete midbrain transection does not prevent the high rate of aldosterone secretion caused by hemorrhage or caval constriction in the dog. Renin and potassium are other powerful stimulators of aldosterone production, and it is becoming increasingly evident that mineralocorticoids also play an important role in the G.A.S. However, according to recent observations, ACTH stimulates mostly the production of nonaldosterone mineralocorticoids.

Corticoids

B28,608/48

In man, exposure to heat and intense muscular exercise increase the rate of corticoid excretion in sweat more than in urine. Hence, "it is a reasonable assumption that it indicates an activation of the adrenal cortex in response to the stresses of heat and strenuous exertion. Our results also emphasize the

fact that in stresses associated with sweating, a significant fraction of the total corticoid excretion is accounted for in the sweat."

Swingle, W. W., Eisler, M., Ben, M., Maxwell, R., Baker, C., Le Brie, S. J.: "Eosinopenia induced by stress in adrenalectomized dogs." *Am. J. Physiol.* **178**: 341-345 (1954). B97,928/54

In adrenalectomized dogs maintained on DOC, stress still elicits eosinopenia. It is assumed that glucocorticoids are not totally indispensable for this reaction and that under certain circumstances, eosinopenia may also be produced through the discharge of catecholamines or other adrenal mechanisms.

Perrini, M., Bonomo, L., Ferrara, R., Leonardi, M.: "Degradazione del cortisone da parte del fegato di ratti normali e sottoposti a stress" (Degradation of cortisone [adrenocortical preparation] by the liver of normal rats and of rats under stress). *Folia Endocrinol. In rats, the anti-inflammatory effect (granuloma pouch technique) of restraint during starvation can, whereas that of cortisol cannot, be largely inhibited by food administration. Several other glucocorticoid effects dissimilar to those elicited by stress are discussed (30 refs.).

Hilton, J. G.: "Adrenocorticotrophic action of antidiuretic hormone." *Circulation* **21**: 1038-1046 (1960). C90,262/60

In hypophysectomized dogs, direct perfusion of the adrenals with synthetic lysine, arginine or acetyl arginine-vasopressin stimulated the cortex to secrete cortisol. Pressor activity and adrenotropic effects were independent of each other. Similar polypeptides such as oxytocin, insulin, glucagon and pressor amines (EP, NEP), did not cause cortisol secretion under identical conditions. However, ACTH was active and increased the rate of aldosterone production. "The probable role of arginine vasopressin as an important factor in the stress reaction is considered along with its postulated ability to activate adrenal phosphorylase."

Hilton, J. G., Scian, L. F., Westermann, C. D., Nakano, J., Kruesi, O. R.: "Vasopressin stimulation of the isolated adrenal glands: nature and mechanism of hydrocortisone secretion." *Endocrinology* **67**: 298-310 (1960). C90,686/60

In hypophysectomized dogs, direct arterial perfusion of the adrenals with synthetic lysine, arginine or acetyl arginine-vasopressin stimulates cortisol secretion. Similar polypeptides, such as oxytocin, insulin and glucagon, as well as EP and NEP, do not produce this effect. ACTH consistently increases aldosterone secretion under identical conditions after hypophysectomy.

Sayers, G., Royce, P. C.: "Regulation of the secretory activity of the adrenal cortex." In: Astwood, E. B., *Clinical Endocrinology*, Vol. 1, pp. 323-334. New York and London: Grune & Stratton, 1960. D143/60

Review of the authors' earlier work which confirms that ACTH is the stimulant for glucocorticoid secretion but has only a minor role in the discharge of aldosterone. "A center in the brain, in or near the pineal complex, elaborates a hormone which acts directly on the glomerulosa of the adrenal to exert the major regulatory influence on the rate of secretion of aldosterone. The hormone has been appropriately named adrenoglomerulotropin (or glomerulotropin)." The stimulatory mechanisms of these two hormones are summarized in Figure 19 (p. 1081).

Davis, J. O., Anderson, E., Carpenter, C. C. J., Ayers, C. R., Haymaker, W., Spence, W. T.: "Aldosterone and corticosterone secretion following midbrain transection." *Am. J. Physiol.* **200**: 437-443 (1961). D2,868/61

In dogs, "complete midbrain transection does not interfere with the high rate of aldosterone secretion which occurs in response to acute blood loss or following caval constriction if venous pressure is maintained at the high control level."

Holzbauer, M.: "The part played by ACTH in determining the rate of aldosterone secretion during operative stress." *J. Physiol. (Lond.)* **172**: 138-149 (1964). D17,639/64

In dogs, ACTH increases not only glucocorticoid but to some extent also aldosterone secretion. Both these corticoids are produced at a subnormal level after hypophysectomy.

Paré, W. P., McCarthy, T. E.: "Urinary sodium and potassium and prolonged en-

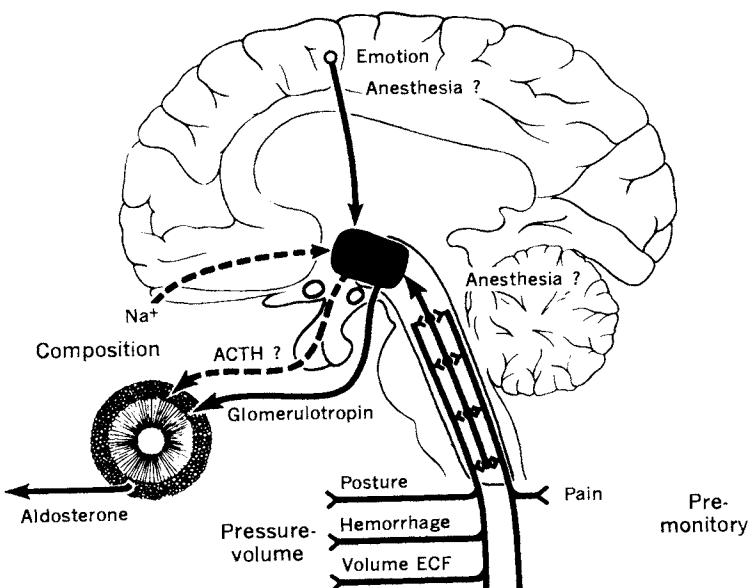

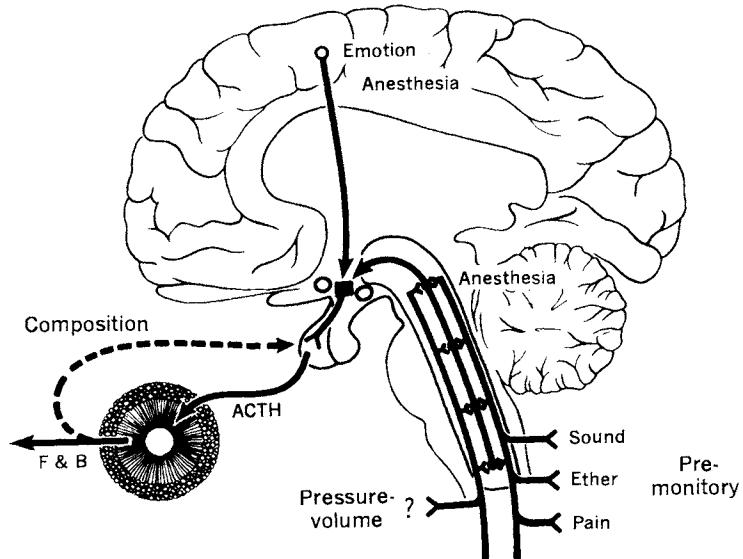

Figure 19. Top. Regulation of ACTH output. Bottom. Regulation of adrenoglomerulotropin (glomerulotropin) output. (Reproduced from *Clinical Endocrinology*, Vol. 1, Figs. 6 and 7, p. 333 (1960) by permission of G. Sayers and P. C. Royce and Grune & Stratton.) [The existence of a "glomerulotropin" is still in doubt (H.S.).]

vironmental stress." *J. Genet. Psychol.* **108**: 135-142 (1966). J21,567/66

Rats exposed to stressors (sound, electroshock) "manifest a significant eosinopenia and adrenal hypertrophy. Estimates of Na and K during the stress period do not manifest a shift in electrolyte balance for stress animals. The authors conclude that the adrenal mineralocorticoids do not participate in the physiological response to chronic environmental stress."

Vecsei, P., Kessler, H.: "In vivo conversion of corticosterone into aldosterone in rats treated with ACTH or submitted to stress." *Experientia* **26**: 1015-1016 (1970).

H31,555/70

Studies on the in vivo conversion of corticosterone to aldosterone in rat adrenals revealed a diminution after ACTH pretreatment, but not upon chronic exposure to other stressors. It is concluded that the adrenocortical effect of stress is not mediated exclusively through ACTH secretion.

Warburton, D. M.: "Modern biochemical concepts of anxiety. Implications for psychopharmacological treatment." *Int. Pharmacopsychiatry* **9**: 189-205 (1974).

J21,388/74

In man, "corticosteroids produce agitation and enhance anxiety. It is proposed that anxiety results from the neurochemical changes induced by corticosteroids. Evidence was presented to show that the critical changes for anxiety are due to modifications in serotonin pathways in the tegmental region of the midbrain."

Pratt, J. H., Melby, J. C.: "Alterations in aldosterone metabolism induced by adrenocorticotropin (ACTH)" (abstracted). *Program Am. Soc. Clin. Invest.*, 66th Ann. Meeting, p. 62a. Atlantic City, N.J., 1974.

H88,771/74

In man, "repository ACTH injected every 12 h for 6 days induced a five-fold increment in the aldosterone secretion rate and a four-fold increment in urinary tetrahydroaldosterone excretion by day 6, whereas plasma concentrations of aldosterone did not change significantly." It appears that increased mineralocorticoid activity after ACTH is due almost exclusively to the enhanced production of nonaldosterone mineralocorticoids. Probably, "the augmented metabolic clearance rate for aldosterone after ACTH stimulation can to an extent regulate aldosterone activity and may be a mechanism for escape from aldosterone effect."

Corticoid Feedback

The idea that an excess of blood corticoids can depress further production of the same hormones and thereby help maintain homeostasis is very old. It has been known since the nineteenth century that, following removal of one adrenal gland, the other undergoes "compensatory hypertrophy," presumably as a result of some self-regulating mechanism that helps repair the loss. This idea was formulated at a time when it was difficult to accept, since the adrenals were not yet known to have any physiologic function. However, it was subsequently observed that transplants of adrenals do not grow well in the presence of an intact gland, and that regeneration after partial adrenalectomy can be blocked by adrenocortical extract.

An extraordinarily large number of publications dealt and continue to deal with this "corticoid feedback mechanism," since it plays an extremely important role in governing the functional efficacy of the hypothalamo-pituitary-adrenocortical axis during stress. Additional relevant data will be found in the next section on Corticoid "Utilization."

It has been learned that purified corticoids are much more effective than cortical extracts in suppressing ACTH secretion and that this inhibitory effect generally parallels glucocorticoid activity. Hence, some of the highly potent synthetic glucocorticoids are even more efficacious in this respect than cortisol, cortisone or corticosterone. Now, in both experimental and clinical medicine, dexamethasone (a powerful synthetic glucocorticoid) is most frequently employed for the suppression of adrenocortical

growth and secretion. After such a blockade, ACTH release can be readily obtained by CRF but not by ordinarily effective doses of vasopressin or other releasing agents. In fact, stimulation of the dexamethasone-suppressed rat adrenal is a standard technique for the assay of CRF, which is otherwise possible only after surgical destruction of the ME.

In patients, dexamethasone almost completely suppresses ACTH and cortisol secretion, but this inhibition can be overcome by stress even when the blood steroid levels are very high. Patients with Cushing's syndrome are comparatively refractory to dexamethasone inhibition.

Following interruption of corticoid treatment at dose levels sufficient to inhibit the secretory activity of the cortex, stress resistance is diminished; presumably, the atrophic cortical cells require some time to recover their normal structure and functional efficiency. In the event of compensatory atrophy produced by DOC, a decrease in stress resistance is manifest even during hormone treatment, because this virtually pure mineralocorticoid inhibits the hyperglycemia of the alarm reaction (presumably useful as a source of energy during stress) by diminishing glucocorticoid production. These observations, made in 1942, first showed that "overdosage with one of the compounds produced by an endocrine cell can interfere with the production by the same cell of other hormonal compounds." Hence, "symptoms of overdosage with hormones produced by a certain endocrine cell type may coexist with signs of deficiency in the hormone production of the same cell." Since even after maximal suppression of adrenocortical secretion by corticoids, ACTH retains its activity, the blockade cannot be at the adrenal level.

Of course, the fact that prolonged treatment with glucocorticoids makes animals and man comparatively insensitive to ACTH most probably depends merely upon the atrophy of the cortical cells, which prevents them from responding optimally and rapidly to stimulation. It is important to remember, however, that in both mice and rats, an essentially pure mineralocorticoid such as DOC can also cause marked involution of the adrenal cortex. We have designated this negative feedback by corticoids as "compensatory atrophy." In rats exposed to cold, aldosterone suppressed the release of ACTH about one-third as actively as did cortisone, but eight times more than DOC.

Many investigators attempted to analyze the possible role of this mechanism in regulating adrenocortical function during stress. Although it was demonstrated as early as 1940 that not only glucocorticoids, but even DOC can considerably diminish adrenocortical stimulation by various stressors, a few investigators persisted in disregarding these facts. They postulated that during stress corticoid homeostasis can be maintained only because an enhanced corticoid production automatically diminishes ACTH secretion and thus maintains a normal blood ACTH level. This antiquated theory does not require detailed consideration today as it is incompatible with the most generally-accepted characteristic of the stress response: the rise in blood ACTH and corticoids during the alarm reaction. Still, because of the numerous and vehement discussions about this subject in the past, we will return to it again in the next section, Corticoid "Utilization," which lists publications maintaining that stress induces an increased consumption of corticoids and that the resulting drop of these hormones below normal would be the decisive stimulus for the rise in ACTH secretion.

It is noteworthy, however, that the histologic structure of the adrenal cortex after overdosage with gluco- or mineralocorticoids differs somewhat from that of hypophysectomized animals; hence we must conclude that either some pituitary influences can

escape feedback inhibition or that corticoids also have some direct effects upon the adrenal cortex.

Raising the blood glucocorticoid level (by exogenous steroids) several times above that reached during stress still fails to inhibit further ACTH secretion upon exposure to a stressor. These findings, and many of our earliest experiments as well as the observations of other investigators to be discussed again in the section on Corticoid "Utilization," clearly show that it is precisely during stress that ACTH secretion becomes largely independent of blood corticoid levels.

In rats, adrenalectomy causes an immediate increase in plasma corticotropin and a drop in hypophyseal ACTH content. About three weeks are necessary for both these levels to return toward normal.

Adrenalectomy causes a rapid fall followed by a slower elevation of the pituitary ACTH concentration in the rat. The ACTH depletion, but not its subsequent repletion, is prevented by corticosterone.

According to early investigators, the rat plasma ACTH level rises significantly only about ten days after complete adrenalectomy, but as previously mentioned, these claims have not been confirmed. In stressed adrenalectomized rats, intravenous cortisol blocks ACTH release within one or two minutes. This observation illustrates the extraordinary rapidity of the corticoid feedback action. (Yet perhaps adjustment to stress is much more rapid than to adrenal insufficiency.) It must be emphasized that not only the discharge but also the adenohypophyseal storage of ACTH (and presumably its synthesis) are blocked by corticoids. It would appear that CRF is not only an ACTH-releasing factor but also one that promotes its manufacture in the adenohypophysis.

In midbrain-sectioned rats, the corticoid feedback mechanisms are slow both after a drop (uniadrenalectomy) or a rise (dexamethasone) of blood corticoids. The mid-brain may act as a modulator of ACTH control without being indispensable for it.

Dexamethasone-induced inhibition of ACTH secretion is more pronounced in intact than in hypothalamically deafferented rats. Presumably, the negative feedback occurs in the hypothalamus but is modified by extrahypothalamic structures.

Implantation of glucocorticoids into the ME region is particularly effective in blocking ACTH secretion.

In rats with diabetes insipidus produced by hypothalamic lesions, compensatory atrophy of the adrenals can still be elicited by cortisol. Large doses of cortisol diminish the antidiuretic response to electric shocks and decrease the plasma vasopressin titer in stressed rats. It was concluded that corticoids block the release of ACTH both by a direct effect upon the pituitary and by diminishing the secretion of vasopressin that can stimulate ACTH release, although it is much less active than CRF in this respect.

Contrary to the most generally-accepted views, certain observations suggest that dexamethasone acts mainly on the adenohypophysis to inhibit ACTH secretion, because its blocking effect is not prevented by extensive lesions in the ME of the rat. Furthermore, it has been claimed that dexamethasone can suppress the corticotrophic action of vasopressin and hypothalamic extract. As previously mentioned, several investigators agree that some of the corticoid feedback may occur at the adenohypophyseal level, but according to the majority opinion, blockade at the ME level is much more important.

Dexamethasone inhibits the release of ACTH in adenohypophyseal monolayer tissue cultures. This is further proof that some direct corticoid feedback in the anterior lobe is possible, even if quantitatively not very important.

There is also some evidence that basal and stress-induced ACTH discharges are subject to corticoid feedback in different areas and that the mechanisms underlying the two phenomena may be dissociated.

The fact that some feedback inhibition has been obtained by glucocorticoid pellets placed in the forebrain of the rat might depend upon hormone transport through the ventricular system to a single feedback site in the basal hypothalamus or adenohypophysis.

In cats, intracerebral microinjections of cortisol considerably altered the unit activity of neurons, as indicated by their firing rate. The results suggest reciprocation between the midbrain and the contralateral posterior diencephalon. Neurons in the posterior diencephalon appear to be more sensitive to local application of cortisol than those in the midbrain.

In conscious, chair-confined monkeys, the rise in plasma 17-OHCS following intravenous cortisol is modified by electric stimulation of certain brain regions. A negative feedback effect of injected cortisol is demonstrable after stimulation of the amygdaloid but not of the hypothalamic nuclei. The results suggested that the neural mechanism for negative feedback is located between the amygdala and the hypothalamus.

In hypophysectomized rats with ten heterotopic pituitary transplants, neither cortisol implants in the ME nor even destruction of the latter depresses adrenocortical function, whereas systemic administration of larger doses of dexamethasone blocks corticoid secretion, even under these conditions. Cortisol implants in the ME caused adrenal atrophy only in intact rats, not in those with heterotopic pituitaries. Hence, it was concluded that the ME may be of importance in feedback regulation of ACTH only by virtue of its location at the source of the portal blood supply. Larger quantities of pituitary tissue can secrete an adequate amount of ACTH even without stimulation by CRF from the ME. In other words, ACTH secretion would not be necessarily dependent upon, but only quantitatively enhanced by, CRF.

Inhibition of CRF and hence of ACTH secretion by glucocorticoids results in manifest EM changes in the ME of the rat. This confirms the current view that corticoid feedback occurs mainly, if not exclusively, at the ME level. However, some inhibitory feedback action upon the adenohypophyseal cells themselves has not been completely excluded, mainly because heavy chronic overdosage with dexamethasone does appear to diminish the sensitivity of the anterior lobe even to CRF, though only to a very mild degree.

In rats, the spontaneous firing of hypothalamic single cell units was increased by hypothalamic deafferentation, and could not be diminished by cortisol. However, time studies revealed an initial reduction in the rate of discharge related to decreased ACTH secretion during corticoid feedback. Dexamethasone-sensitive neurons are situated over wide areas of the hypothalamus and midbrain; in most of these, firing is stimulated, but in some it is inhibited, by the corticoid. NEP and dopamine suppressed, whereas acetylcholine activated, the dexamethasone-sensitive neurons. Hence, the latter are apparently responsive both to corticoids and to other humoral mediators.

In rats, ACTH concentration in the intermediate lobe is considerably higher than in the adenohypophysis. However, one month after adrenalectomy, the ACTH content of the anterior lobe increased threefold, whereas that of the intermediate lobe remained unchanged. After treatment with cortisol the ACTH concentration in the adenohypophysis diminished markedly; in the intermediate lobe, no significant change occurred.

There is much evidence that protein-bound corticosterone has little, if any, inhibitory effect upon ACTH discharge.

In rats, thyroxine increases transcortin binding sites, thereby inhibiting corticoid feedback, since only the unbound and not the total corticosterone concentration is effective in this respect. On the other hand, in man, cortisol cancels the enhancing effect of thyroxine on transcortin binding.

Implantation of corticosterone pellets in neonatal rats may exert a permanent suppressive effect upon corticoid production, detectable even during adult life.

A distinction has also been made between "fast feedback," which occurs within minutes following treatment with small doses of corticosterone in rats under surgical stress, and "delayed feedback," which commences only after one hour and requires larger doses of corticosterone but is of longer duration. Some corticoids are synergists, others antagonists, in these feedbacks which are said to have different mechanisms and separate receptors. According to recent investigations, delayed corticoid feedback exists at both the hypothalamic and the pituitary levels, whereas fast feedbacks are mediated only through the hypothalamus.

Several investigators have attempted to design schematized models indicating the various sites at which stimulators and inhibitors of ACTH release take effect. These are undoubtedly useful in clarifying our views about the underlying mechanisms, but because of the innumerable conditioning factors that modify such responses *in vivo*, we are still very far from being able to use such models as a basis for prediction of the reactions that will occur under given circumstances.

There is some evidence that cortisol suppresses not only ACTH but also STH secretion.

Corticoid Feedback

(See also our earlier stress monographs, p. xiii, and Mathematical Models under Various Other Theories)

Stilling, H.: "Note sur l'hypertrophie compensatrice des capsules surrenales" (Notes on compensatory hypertrophy of the adrenal glands). *Rev. Méd. (Paris)* 8: 459-461 (1888). 35,886/1888

In young unlike in old rabbits, the removal of one adrenal causes an immediate lipid discharge followed by mitoses in the cortical cells, eventually resulting in "compensatory hypertrophy." This contradicts the view still held by many (in 1888!) that the adrenals have no physiologic function.

Ingle, D. J., Kendall, E. C.: "Atrophy of the adrenal cortex of the rat produced by the administration of large amounts of cortin." *Science* 86: 245 (1937). 68,992/37

It has been shown that transplants of adrenals in the rat do not regenerate in the presence of one intact gland. Furthermore, the regeneration of enucleated adrenals is

blocked by adrenocortical extract, and intravenous injection of the latter causes adrenal atrophy unless ACTH is simultaneously administered. It is concluded that "when the physiologic requirements for cortin are increased there is an increase in the output of the adrenotropic principle, and when cortin is present in the body fluids in excess of physiologic requirements the output of adrenotropic secretions from the pituitary is suppressed."

Ingle, D. J.: "The effects of administering large amounts of cortin on the adrenal cortices of normal and hypophysectomized rats." *Am. J. Physiol.* 124: 369-371 (1938).

90,976/38

Normal rats treated with "cortin" (adrenocortical extract) exhibit cortical atrophy.

Ingle, D. J., Higgins, G. M., Kendall, E. C.: "Atrophy of the adrenal cortex in the rat produced by administration of large amounts of cortin." *Anat. Rec.* 71: 363-372 (1938).

72,172/38

In rats, adrenocortical atrophy can be produced by injections of "cortin," which blocks

the action of adrenotropic anterior pituitary preparations. [This seemingly induced insensitivity to ACTH was probably due to inappropriate proportions of the latter and the injected corticoids. Actually, this observation might have served as the first proof of a corticoid feedback upon ACTH production but, as published, the phenomenon appeared to result from insensitivity of the cortical cells (H.S.).]

Selye, H.: "Compensatory atrophy of the adrenals." *J.A.M.A.* **115**: 2246-2252 (1940).

A32,884/40

In both mice and rats, DOC causes marked involution of the adrenal cortex, presumably through inhibition of ACTH production; yet the histologic structure of these adrenal cortices differs somewhat from that in hypophysectomized rodents. The phenomenon is designated as "compensatory atrophy."

Selye, H., Dosne, C., Bassett, L., Whitaker, J.: "On the therapeutic value of adrenal cortical hormones in traumatic shock and allied conditions." *Can. Med. Assoc. J.* **43**: 1-8 (1940). A32,768/40

In rats, prolonged treatment with DOC causes adrenocortical atrophy, and to some extent even prevents the adrenal enlargement normally produced by stressors (for example, surgical trauma).

Selye, H., Dosne, C.: "Physiological significance of compensatory adrenal atrophy." *Endocrinology* **30**: 581-584 (1942).

A37,249/42

In rats, large doses of DOC inhibit but do not prevent the adrenal enlargement characteristic of the alarm reaction following treatment with such stressors as cold, formaldehyde, atropine, trauma or forced muscular exercise. As a result of this inhibition, the resistance of the DOC-treated animals to stressors is subnormal, since they are unable to produce optimal amounts of glucocorticoids. The hyperglycemia of the alarm reaction (presumably useful in providing energy during stress) is likewise diminished by DOC pretreatment. It is apparent that "overdosage with one of the compounds produced by an endocrine cell can interfere with the production by the same cell of other hormonal compounds (in this case corticoids, such as corticosterone, active in carbohydrate metabolism). As a result of this interference, symptoms of overdosage with hormones produced by a certain endocrine cell type may

coexist with signs of deficiency in the hormone production of that same cell."

Tepperman, J., Engel, F. L., Long, C. N. H.: "A review of adrenal cortical hypertrophy." *Endocrinology* **32**: 373-402 (1943). A58,184/43

Houssay, B. A., Pinto, R. M.: "Interrelación hipófiso-suprarrenal demostrada por parabiosis" (Hypophyse-adrenal interrelation, as demonstrated by parabiosis). *Rev. Soc. Argent. Biol.* **20**: 39-48 (1944).

A94,483/44

In a pair of parabiotically united rats, adrenalectomy of one twin causes adrenal hypertrophy and thymus atrophy in its partner. This response is diminished by DOC administration.

Sayers, G., Sayers, M. A.: "Regulatory effect of adrenal cortical extract on elaboration of pituitary adrenotropic hormone." *Proc. Soc. Exp. Biol. Med.* **60**: 162-163 (1945).

B1,108/45

In rats, adrenocortical extract prevents the loss of adrenal ascorbic acid following exposure to cold, but it does not interfere with the effect of exogenous ACTH. Presumably, the "rate of release of adrenotropic hormone from the pituitary is regulated by the concentration of adrenal cortical hormones in the blood and tissues."

Moya, F., Selye, H.: "Effect of desoxycorticosterone upon hypophyseal corticotrophin production." *Proc. Soc. Exp. Biol. Med.* **68**: 529-531 (1948). B19,381/48

Even enormous anesthetic doses of DOC cannot prevent the decrease in adrenal ascorbic acid content following exposure to cold. Hence, mere lack of corticoids cannot be the decisive cause of ACTH discharge during stress.

Taylor, A. B., Albert, A., Sprague, R. G.: "Adrenotropic activity of human blood." *Endocrinology* **45**: 335-343 (1949).

B39,400/49

In patients with adrenal cortical insufficiency, ACTH could be demonstrated in the blood via a method that failed to show its presence in normal controls.

Gemzell, C. A., Dyke, D. C., Van, Tobias, C. A., Evans, H. M.: "Increase in the formation and secretion of ACTH following adrenalectomy." *Endocrinology* **49**: 325-336 (1951). B62,285/51

In rats, adrenalectomy causes an immediate increase in plasma ACTH with a corre-

sponding drop in the ACTH content of the adenohypophysis. The steady state is reached after approximately three weeks, at which time the ACTH levels in both plasma and pituitary are about normal.

Long, C. N. H.: "Regulation of ACTH secretion." *Rec. Prog. Horm. Res.* **7**: 75-97 (1952). B68,650/52

Review of the mechanism of ACTH secretion, which is thought to be regulated partly by the ACTH and corticoid concentration of the blood (feedback) and partly through direct stimulation by EP and sympathetic nervous stimuli (49 refs.).

Abelson, D., Baron, D. N.: "The effect of cortisone acetate on adrenal ascorbic acid depletion following stress." *Lancet* October 4, 1952, pp. 663-664. B74,513/52

Forgács, P., Hajdu, L.: "Adrenocorticotrop hormon (ACTH) elválasztás gátlása cortisonnal" (Inhibition of adrenocorticotrophic hormone [ACTH] secretion by cortisone). *Kisér. Orvostud.* **5**: 444-448 (1953) (Hungarian). B95,464/53

In unilaterally adrenalectomized rats, cortisone prevents ACTH discharge, whereas ascorbic acid does not. Exogenous ACTH retains its corticoid-mobilizing effect despite excess exogenous cortisone, which indicates that the block is not at the adrenal level.

Hodges, J. R.: "Review article. The pituitary-adrenal relationship." *J. Pharm. Pharmacol.* **8**: 481-496 (1953).

J7,386/53

Review of the early literature on corticoids inhibiting ACTH secretion during stress (98 refs.).

Hodges, J. R.: "The effect of desoxycorticosterone acetate on the release of adrenocorticotrophin by the pituitary gland." *Br. J. Pharmacol.* **8**: 242-247 (1953).

B86,006/53

In rats, adrenal ascorbic acid depletion after unilateral adrenalectomy was only partially inhibited by DOC, and "since ACTH was still effective in producing adrenal ascorbic acid depletion, it was considered that DOCA had not prevented the stress-induced fall in adrenal ascorbic acid concentration by a direct action on the adrenal cortex." In fact, very large doses of intraperitoneal DOC caused adrenal ascorbic acid depletion by themselves.

Renzi, A. A., Gilman, M., Gaunt, R.: "ACTH-suppressing action of aldosterone."

Proc. Soc. Exp. Biol. Med. **87**: 144-145 (1954). B99,669/54

In rats exposed to cold, aldosterone suppressed the release of ACTH about one-third as actively as cortisone, but eight times more than DOC.

Hodges, J. R.: "The effect of cortisone acetate on the secretion of adrenocorticotrophic hormone by the adenohypophysis." *J. Endocrinol.* **10**: 173-178 (1954).

B90,265/54

In rats, cortisone given subcutaneously or orally elicited no change in adrenal ascorbic acid content but it reduced the latter considerably upon intraperitoneal administration. This "was apparently due to a nonspecific effect caused by the intraperitoneal administration of suspended matter." Pretreatment of rats with large doses of cortisone diminished, but did not abolish, the ascorbic acid depletion normally produced by unilaterally adrenalectomy.

Sydnor, K. L.: "Blood ACTH in the stressed adrenalectomized rat after intravenous injection of hydrocortisone." *Endocrinology* **56**: 204-208 (1955). C1,808/55

In stressed adrenalectomized rats, intravenous cortisol blocks ACTH release within one or two minutes.

Farrell, G. L., Laqueur, G.: "Reduction of pituitary content of ACTH by cortisone." *Endocrinology* **56**: 471-473 (1955).

J12,872/55

In dogs, cortisone decreases the ACTH content of the pituitary.

Roberts, S., Keller, M. R.: "Influence of epinephrine and cortisone on the metabolism of the hypophysis and hypothalamus of the rat." *Endocrinology* **57**: 64-69 (1955).

C6,336/55

Barrett, A. M., Hodges, J. R.: "The effect of stress on the level of adrenocorticotrophin in the plasma of normal and adrenalectomized rats." *J. Endocrinol.* **14**: 292-296 (1956). C25,992/56

The literature on Sayers' feedback theory of corticoid secretion during stress is reviewed, and the concept is rejected because adrenalectomized animals, which have a high ACTH level, show a further increase in response to stress. Furthermore, sham and true adrenalectomies produce almost identical elevations of blood ACTH.

Rose, S., Nelson, J.: "Hydrocortisone and

A.C.T.H. release." *Aust. J. Exp. Biol. Med. Sci.* **34**: 77-80 (1956). C23,003/56

In rats with a micro-injector permanently implanted in the hypophyseal fossa or next to it, cortisol is much more effective in preventing compensatory hypertrophy of the contralateral gland following unilateralec-tomy when applied directly to the hypophysis than when injected elsewhere. "These experiments support the view that adrenal steroids act directly at the level of the pars distalis to inhibit ACTH release." [It would be difficult to exclude the possibility that the corticoids injected into the hypophyseal fossa did not also reach the ME in a higher concentration than when administered at a distance from the hypophysis (H.S.).]

Ohler, E. A., Sevy, R. W.: "Inhibition of stress induced adrenal ascorbic acid depletion by morphine, dibenzylidine, and adrenal cortex extract." *Endocrinology* **59**: 347-355 (1956). C23,020/56

In rats the adrenal ascorbic acid depletion produced by sham adrenalectomy, unilateralec-tomy, EP, hydroxyamphetamine or vasopressin could be inhibited by morphine. Adrenocortical extract blocked the response to operative stress and to catecholamines but not to vasopressin. Dibenzylidine suppressed only the reaction to catecholamines.

Collins, E. J.: "Steroid-induced adrenal-pituitary hypofunction." *Endocrinology* **58**: 777-780 (1956). C17,662/56

In rats, cortisol-induced adrenocortical atrophy depends on an effect upon the pituitary, not the adrenal. The latter, although rendered atrophic by the glucocorticoid, responds normally to ACTH.

Brodish, A., Long, C. N. H.: "Changes in the blood ACTH under various experimental conditions studied by means of a cross-circulation technique." *Endocrinology* **59**: 666-676 (1956). C26,209/56

A unilaterally or bilaterally adrenalectomized rat was united by crosscirculation with a hypophysectomized partner at various times after application of a stimulus to ACTH release, which could be measured by the changes in adrenal ascorbic acid in the hypophysectomized animal. "The high rate of ACTH secretion, following the application of a severe stress such as unilateral or bilateral adrenalectomy, can be maintained for approximately two hours, after which time the blood ACTH level gradually diminishes and is not detectable in 6 hours. However,

after a milder stress, such as that associated with the cannulation of the femoral blood vessels prior to cross-circulation, a steady moderate rate of ACTH secretion can be maintained throughout a 12-hour period studied. The disappearance of ACTH from the blood 6 hours after a severe stress is not due to increased blood level of adrenal cortical hormones, since it also occurs after bilateral adrenalectomy. Neither is this phenomenon due to exhaustion of pituitary ACTH, for if a second stress is applied at this time, marked elevation of blood ACTH occurs." Following application of a severe stress, the ACTH secretion curve is biphasic, suggesting a dual mechanism of its regulation.

Langecker, H., Lurie, R.: "Die Hemmung der Corticotropin-Sekretion durch Steroide" (The suppression of corticotropin secretion by steroids). *Acta Endocrinol.* **25**: 54-58 (1957). C43,951/57

In unilateralec-tomized rats, compensatory hypertrophy of the contralateral gland can be suppressed by cortisone, cortisol or DOC, but not by 17 α -hydroxyprogesterone, pregnan-21-ol-3,20-dione, or dehydroepiandrosterone. "Animals, which have received cortisone, are insensitive to corticotrophin. Because this effect is also found in hypophysecomized animals, an adrenal mechanism is discussed."

Richards, J. B., Pruitt, R. L.: "Hydrocortisone suppression of stress-induced adrenal 17-hydroxycorticosteroid secretion in dogs." *Endocrinology* **60**: 99-104 (1957).

C27,393/57

In pentobarbital-anesthetized dogs, maximal adrenal 17-OHCS secretion occurred when the dogs were subjected to the stressor effect of exposure to 20 percent carbon dioxide or the surgical trauma of adrenal vein cannulation. In either case, the adrenocortical stimulation was depressed by constant intravenous infusion of cortisol for one hour prior to and during stress.

Wexler, B. C., Dolgin, A. E., Zaroslinski, J. F., Tryczynski, E. W.: "Effects of a bacterial polysaccharide (Piromen) on the pituitary-adrenal axis: cortisone blockade of Piromen-induced release of ACTH." *Endocrinology* **63**: 201-204 (1958).

C56,640/58

In rats, ACTH release by bacterial polysaccharide (Piromen) is blocked by cortisone but not by DOC.

Birmingham, M. K., Kurlents, E.: "Inactivation of ACTH by isolated rat adrenals and inhibition of corticoid formation by adrenocortical hormones." *Endocrinology* **62**: 47-60 (1958). D78,083/58

Schapiro, S., Marmorston, J., Sobel, H.: "The steroid feedback mechanism." *Am. J. Physiol.* **192**: 58-62 (1958).

C47,514/58

The four-hour eosinopenia was used as a criterion for ACTH secretion in rats. DOC inhibited endogenous ACTH mobilization following stress in intact rats, probably "by blocking the secretion from a cerebral structure, presumably the hypothalamus, of a pituitary stimulating substance."

McCann, S. M., Fruit, A., Fulford, B. D.: "Studies on the loci of action of cortical hormones in inhibiting the release of adrenocorticotropic hormone." *Endocrinology* **63**: 29-42 (1958). J12,362/58

In rats with diabetes insipidus produced by hypothalamic lesions, compensatory adrenal atrophy can still be elicited by cortisol. Large doses of cortisol diminish the antidiuretic response to a mild electric shock and decrease the vasopressor titer in the peripheral blood of stressed rats. "It was concluded that adrenal steroids block the release of ACTH from the pituitary by 1) a direct action on the pituitary gland, and 2) by decreasing the release of antidiuretic hormone, the presumed neuro-humor stimulating ACTH release" (24 refs.).

Halász, B.: "Der zeitliche Ablauf von Veränderungen des Kernvolumens in der Nebennierenrinde" (The chronologic development of changes in cell nuclear volume in the adrenal cortex). *Acta Morphol. Acad. Sci. Hung.* **8**: 193-198 (1958).

J13,017/58

In the glomerulosa of the rat adrenal cortex, DOC induces a shrinkage of the nuclei during the first three days, followed by a swelling; only after the first week does the characteristic diminution in nuclear size become fully evident and persistent. The fasciculata shows no typical variations. ACTH acts mainly on the fasciculata, causing an initial swelling followed by a shrinkage in nuclear size which after three to five days leads to a persistent and considerable enlargement. Earlier data on the histologic actions induced by DOC and ACTH in the adrenal cortex are reviewed (7 refs.).

Hodges, J. R., Vernikos, J.: "Influence of

circulating adrenocorticotrophin on the pituitary adrenocorticotropic response to stress in the adrenalectomized rat." *Nature* **182**: 725 (1958). C61,601/58

In rats, adrenalectomy first increases the ACTH content of the pituitary, but at least two weeks are required before it adapts itself also to secrete and maintain a great excess of this hormone. Tests performed at various intervals during this time showed that the largest increase in circulating ACTH occurred in rats with the lowest initial blood values, and apparently the high serum level of ACTH inhibits its own secretion through an "auto feedback" mechanism.

Kitay, J. I., Holub, D. A., Jailer, J. W.: "Hormonal regulation of pituitary adrenocorticotrophin." *Proc. Soc. Exp. Biol. Med.* **97**: 165-169 (1958). C47,220/58

As determined by in vitro bioassays, "ACTH administration and adrenalectomy both resulted in a striking increase in pituitary ACTH content. Epinephrine and cortisone administration were both followed by significant depletion of pituitary ACTH."

Cox, G. S., Hodges, J. R., Vernikos, J.: "The effect of adrenalectomy on the circulating level of adrenocorticotropic hormone in the rat." *J. Endocrinol.* **17**: 177-181 (1958). C55,901/58

In rats, blood ACTH levels rose significantly only about ten days after complete adrenalectomy. Apparently, the pituitary requires a long time to adapt itself by increasing ACTH output after total deprivation of corticoids.

Kitay, J. I., Holub, D. A., Jailer, J. W.: "Extra-adrenal action of exogenous ACTH; inhibition of pituitary ACTH secretion." *Fed. Proc.* **17**: 87 (1958). C51,673/58

In adrenalectomized rats, ACTH increases, whereas cortisone decreases, the ACTH content of the pituitary. During exposure to a standard stressor, exogenous ACTH inhibits the usual release from the adenohypophysis. Presumably, that is why the hormone accumulates in the gland when exogenously administered.

Fortier, C., Groot, J. de: "Adenohypophyseal corticotrophin and plasma free corticosteroids during regeneration of the enucleated rat adrenal gland." *Am. J. Physiol.* **196**: 589-592 (1959). C65,671/59

Observations on partially adrenalectomized rats suggest that "both release and synthesis of ACTH are accelerated by hypo-

and depressed by hypercorticoidism." Yet the effect is predominantly exerted on synthesis.

Wied, D. de, Mirsky, I. A.: "The action of Δ^1 -hydrocortisone on the antidiuretic and adrenocorticotropic responses to noxious stimuli," *Endocrinology* **64**: 955-966 (1959).

C69,492/59

Rats given large doses of prednisolone do not exhibit a decrease in adrenal ascorbic acid concentration after exposure to painful stimuli or injection with histamine or nicotine, and they respond normally to ACTH. The dose of intraperitoneal vasopressin needed to produce a significant decrease in adrenal ascorbic acid is about ten times above normal. The antidiuretic response to stress is likewise suppressed by large doses of prednisolone. Presumably, this glucocorticoid "does not affect the responsiveness of the hypothalamus, it decreases markedly the responsiveness of the adenohypophysis and neurohypophysis of animals exposed to noxious stimuli."

Reck, D. C., Fortier, C.: "Adrenal ascorbic acid and corticosteroidogenesis following unilateral adrenalectomy in the rat," *Proc. Soc. Exp. Biol. Med.* **104**: 610-613 (1960).

C92,939/60

Following unilateral adrenalectomy in rats, adrenal ascorbic acid depletion is more closely related in time to release than to synthesis of corticosterone.

Péron, F. G., Moncloa, F., Dorfman, R. I.: "Studies on the possible inhibitory effect of corticosterone on corticosteroidogenesis at the adrenal level in the rat," *Endocrinology* **67**: 379-388 (1960).

C90,696/60

Hypophsectomized rats and the adrenals of intact rats maintained *in vitro* showed diminished corticoid production following the administration of ACTH in the presence of excess corticosterone. Presumably, "the circulating levels of blood corticosterone in the

rat may control its production by acting directly on the adrenal gland by inhibiting the action of ACTH." [In an addendum, the authors state that the *in vitro* experiments could not be confirmed subsequently; however, ACTH stimulation of the adrenals of hypophsectomized rats *in vivo* was inhibited by both cortisol and cortisone (H.S.).]

Hodges, J. R., Vernikos, J.: "The effects of hydrocortisone on the level of corticotrophin in the blood and pituitary glands of adrenalectomized and of stressed-adrenalectomized rats," *J. Physiol. (Lond.)* **150**: 683-693 (1960).

C84,916/60

In adrenalectomized rats, the blood ACTH level was high but rose even further under stress (ether anesthesia). Large doses of cortisol, given intravenously 180 seconds after stress, rapidly reduced the high blood concentration of ACTH, but only to the pre-existing level. Adrenalectomy resulted in a slight fall followed by a marked rise in pituitary ACTH. This elevation was also prevented by cortisol. The latter almost completely inhibited the rise in blood ACTH after adrenalectomy, but it did not block the marked elevation of the blood levels caused by stress. "The results add further support to the hypothesis that the action of corticoids in controlling pituitary adrenocorticotropic activity is mainly on corticotrophin synthesis."

Endrőczi, E., Lissák, K., Tekeres, M.: "Hormonal 'feed-back' regulation of pituitary-adrenocortical activity," *Acta Physiol. Acad. Sci. Hung.* **18**: 301-307 (1961) (13 refs.).

Yates, F. E., Leeman, S. E., Glenister, D. W., Dallman, M. F.: "Interaction between plasma corticosterone concentration and adrenocorticotropin-releasing stimuli in the rat: evidence for the reset of an endocrine feedback control," *Endocrinology* **69**: 67-80 (1961).

D7,734/61

Experiments on rats given varying doses of histamine (which increases corticosterone production) in combination with corticosterone support "the hypothesis that the rapid rises in plasma corticosteroid concentration which follow many varied stimuli are caused by a reset of the negative feedback con-

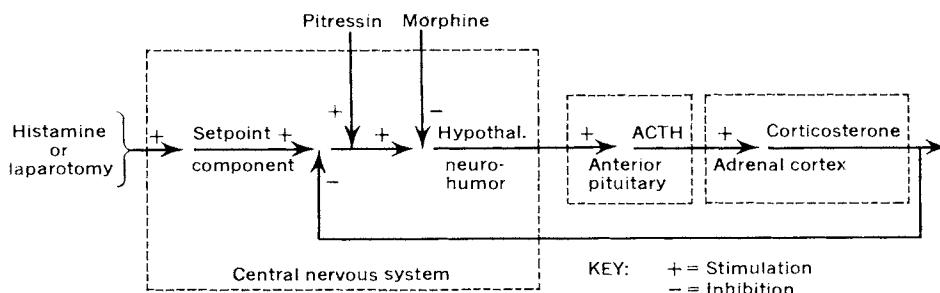

Figure 20. Relative localization of ACTH-releasing actions of nonspecific stimuli (histamine, laparotomy), pitressin and hypothalamic neurohumor. The relative localization of sites of inhibition of ACTH release by corticosterone and morphine are also indicated. (Reproduced from *Endocrinology* 70 (1962) by permission of S. E. Leeman *et al.* and Charles C Thomas, Publisher, Springfield, Ill.)

trol of plasma corticosteroid concentration to regulate at higher levels."

Smelik, P. G., Sawyer, C. H.: "Effects of implantation of cortisol into the brain stem or pituitary gland on the adrenal response to stress in the rabbit." *Acta Endocrinol.* (Kh.) 41: 561-570 (1962) D43,088/62

In rabbits, the increase in plasma corticoids induced by restraint was inhibited by implanting cortisol in the anterior ME and in the postoptic region. It was inhibited to a lesser extent by implants in the anteromedial hypothalamus between the supraoptic and paraventricular nuclei and the ME. Similar implants in the posterior hypothalamus, mesencephalon or adenohypophysis were ineffective.

Yates, F. E., Urquhart, J.: "Control of plasma concentrations of adrenocortical hormones." *Physiol. Rev.* 42: 359-443 (1962). D30,548/62

Very meticulous and detailed review of the literature on the stressors and feedback systems responsible for corticoid concentrations in the plasma and tissues (727 refs.).

Leeman, S. E., Glenister, D. W., Yates, F. E.: "Characterization of a calf hypothalamic extract with adrenocorticotropic-releasing properties: evidence for a central nervous system site for corticosteroid inhibition of adrenocorticotropic release." *Endocrinology* 70: 249-262 (1962). D36,341/62

On the basis of observations in rats, a schematic drawing (Figure 20) was constructed that indicates sites at which stimula-

tors and inhibitors of ACTH-release exert their actions.

Kendall, J. W. Jr.: "Studies on inhibition of corticotropin and thyrotropin release utilizing microinjections into the pituitary." *Endocrinology* 71: 452-455 (1962). D31,357/62

In rats, injection of dexamethasone directly into the pituitary "was no more effective in suppressing adrenal venous corticosterone secretion than an equal amount administered subcutaneously."

Hedner, P., Rerup, C.: "Plasma corticosteroid levels and adrenal ascorbic acid after intravenous corticotrophin injections and 'stressful' stimuli in the rat." *Acta Endocrinol.* 39: 527-538 (1962). D21,246/62

In rats the increase in plasma corticoid levels unlike the depletion of adrenal ascorbic acid produced by ether anesthesia is blocked by dexamethasone. The corresponding effects of unilateral adrenalectomy are less readily influenced. Apparently, corticoids can only partially inhibit stress-induced endogenous corticoid discharge. [Of course, if these feedback mechanisms were perfect during stress, the latter could never significantly increase corticoid production (H.S.).]

Hodges, J. R., Vernikos-Danellis, J.: "Pituitary and blood corticotrophin changes in adrenalectomized rats maintained on physiological doses of corticosteroids." *Acta Endocrinol.* 39: 79-86 (1962). D16,314/62

In adrenalectomized rats, the rise in plasma ACTH after mild stress (ether) was greater

than in controls. This hyperexcitability of the pituitary was not diminished by corticoids alone, but was considerably reduced by adrenocortical extracts plus ascorbic acid. Perhaps corticoids control the rate of ACTH synthesis, but other factors, including ascorbic acid, regulate pituitary responsiveness to stress-induced ACTH secretion.

Hodges, J. R., Jones, M. T.: "Corticotrophin release in the cortisol-treated rat." *J. Physiol. (Lond.)* **163**: 391-398 (1962).

D36,943/62

Observations in rats "support the hypothesis that ACTH release is controlled by a dual mechanism. The initial phase of ACTH secretion in response to acute stress is blocked by corticosteroids, but the second prolonged phase in response to chronic stress is not."

McCarty, D. J. Jr.: "The patient on long term adrenocortical steroid therapy." *Am. J. Cardiol.* **12**: 342-345 (1963). E25,875/63

Arnoldsson, H., Helander, E.: "The reaction of the pituitary-adrenocortical system to stress after prolonged corticosteroid therapy." *Acta Med. Scand.* **173**: 769-774 (1963).

James, V. H. T., Landon, J.: "The response of the pituitary-adrenal axis to the infusion of dexamethasone." *J. Endocrinol.* **26**: xxxi-xxxii (1963). E30,543/63

Observations on normal patients suggest that dexamethasone causes virtually complete suppression of ACTH and cortisol secretion, but this inhibition can be overcome by stress, even though the blood steroid levels are extremely high. Patients with Cushing's syndrome are comparatively refractory to dexamethasone inhibition.

Chowers, I., Feldman, S., Davidson, J. M.: "Effects of intrahypothalamic crystalline steroids on acute ACTH secretion." *Am. J. Physiol.* **205**: 671-673 (1963).

E28,859/63

In rats, implantation of crystalline cortisol in the ME region caused adrenal atrophy and inhibition of ACTH secretion after unilateradrenalectomy (adrenal ascorbic acid test). Similar testosterone implants elicited an essentially inverse response. The rats with cortisol implants in the pituitary had normal adrenal weights and ACTH reactions.

Smelik, P. G.: "Relation between blood level of corticoids and their inhibiting effect on the hypophyseal stress response." *Proc.*

Soc. Exp. Biol. Med. **113**: 616-619 (1963).

E21,483/63

In rats, large doses of subcutaneous corticosterone suppressed adrenal corticoid production in vitro following exposure to stress in vivo, but there was no parallelism between this inhibition and the plasma corticosterone levels. "It is concluded that pituitary impairment by corticoid administration is not correlated with the existing blood level of corticoids."

Stark, E., Fachet, J.: "The effect of blood corticoid levels on ACTH-release caused by stress." *Acta Med. Acad. Sci. Hung.* **19**: 367-370 (1963).

G17,876/63

In rats, "pharmacological doses of corticoids suppressed the release of ACTH in the non-stressed animals, they did not inhibit ACTH-release due to formalin: this in spite of the fact that the exogenous hormone levels considerably exceeded the corticosterone concentration following stress. It would appear that the mechanism of the negative feed-back cannot be invoked as the sole explanation for the ACTH-release due to stress."

Smelik, P. G.: "Failure to inhibit corticotrophin secretion by experimentally induced increases in corticoid levels." *Acta Endocrinol. (Kh.)* **44**: 36-46 (1963).

E25,508/63

In rats, corticosterone infusions greatly raising the blood corticosterone levels failed to inhibit adrenocortical activation by histamine or ACTH. "These data are not in agreement with the 'variable set point control theory,' and demonstrate that physiological variations in plasma corticoid concentration do not affect the acute stress-induced corticotrophin release."

Estep, H. L., Island, D. P., Ney, R. L., Liddle, G. W.: "Pituitary-adrenal dynamics during surgical stress." *J. Clin. Endocrinol. Metab.* **23**: 419-425 (1963). D66,683/63

Pelvic laparotomy caused an increase in plasma 17-OHCS, even in patients treated with large doses of dexamethasone before and/or during the operation. Furthermore, secretion of substance S indicated that ACTH continued to stimulate the adrenals; infusions of cortisol, which maintained high blood levels of this natural glucocorticoid, failed to prevent the stress-induced ACTH increase in the plasma. "It is concluded that during the stress of laparotomy the behavior of the human pituitary-adrenal system does

not conform to the specifications of a negative feedback mechanism."

Hodges, J. R., Jones, M. T.: "The effect of injected corticosterone on the release of adrenocorticotrophic hormone in rats exposed to acute stress." *J. Physiol.* (Lond.) **167**: 30-37 (1963). D68,641/63

In rats, "corticosterone in doses sufficient to raise the blood concentration of the steroid to up to four times the maximal level induced by stress did not diminish the further rise in corticosterone or the elevation in blood ACTH and only slightly reduced the adrenal ascorbic-acid depletion normally caused by sham-adrenalectomy." It is concluded that during stress the secretion of ACTH is independent of the blood corticosterone level.

Bohus, B., Endrőczi, E.: "The effect of endogenous diminution of corticosteroid level on pituitary-adrenocortical function." *Acta Physiol. Acad. Sci. Hung.* **25**: 351-358 (1964). G33,534/64

In anesthetized dogs the adrenal vein was directly connected with the hepatic portal circulation; this led to a rapid increase in the corticoid concentration of the adrenal vein blood, which was prevented by morphine. Presumably, "the plasma corticosteroid level increases the pituitary-adrenocortical activity through a hormonal feedback mechanism."

Wied, D. de: "The site of the blocking action of dexamethasone on stress-induced pituitary ACTH release." *J. Endocrinol.* **29**: 29-37 (1964). F10,254/64

In rats, the corticotropic effect of stressors and of lysine-vasopressin was inhibited by dexamethasone given subcutaneously, while that of ACTH was not affected. After extensive lesions in the ME, dexamethasone also suppressed the corticotrophic action of lysine-vasopressin and of hypothalamic extract. Dexamethasone did not significantly change the ACTH content of the pituitary in either intact or lesioned rats. "It is concluded that the blocking action of dexamethasone is located in the anterior pituitary."

Fraschini, F., Mangili, G., Motta, M., Martini, L.: "Midbrain and feedback control of adrenocorticotrophic secretion." *Endocrinology* **75**: 765-769 (1964). F23,994/64

In midbrain-sectioned rats with decreased (unilateral adrenalectomy) or increased (dexamethasone) blood corticoids, the feedback mechanisms are slow. Apparently, "the mid-

brain-sectioned animal does not realize then that its blood levels of corticoids are changed until extremely high or extremely low levels of blood corticoids are reached; only when such values are attained can the servomechanisms responding to these fluctuations thus be brought into play in the midbrain-sectioned animals. The hypothesis is put forward that, in addition to an ACTH-activating, an ACTH-inhibiting and a stress-facilitating system, the midbrain might participate in ACTH control by acting as a sort of modulator."

Hodges, J. R., Jones, M. T.: "Changes in pituitary corticotrophic function in the adrenalectomized rat." *J. Physiol.* (Lond.) **173**: 190-200 (1954). D18,782/64

In rats, adrenalectomy caused a rapid fall, followed by a slower rise, in pituitary ACTH. The ACTH depletion, but not its subsequent repletion, was prevented by corticosterone after adrenalectomy. Mild stressors, which did not significantly affect plasma ACTH in intact rats, considerably raised it after adrenalectomy. The stress-induced ACTH discharge was suppressed by small doses of corticosterone in the adrenalectomized rat, but there was no correlation between the plasma corticosterone concentration and the degree of ACTH inhibition.

Smelik, P. G., Sawyer, C. H.: "Hypothalamic structures involved in the adrenocortical feedback action on pituitary corticotrophin secretion." *Prog. Brain Res.* **5**: 132-134 (1964). J13,013/64

Detailed study on the effect of cortisol implants in various parts of the hypothalamus upon plasma cortisol rises elicited in rabbits by restraint.

Vernikos-Danellis, J., Anderson, E., Trigg, L., Dickinson, J.: "Feedback mechanisms regulating ACTH secretion." *Program 47th Meeting Endocrinol. Soc.*, p. 27. New York, 1965. F39,944/65

In rats bearing ACTH-producing tumors, "inhibition of ACTH secretion by maximal endogenous levels of corticoids is slow to develop and even under conditions when such high levels persist for a considerable length of time the response to stress is not completely prevented. Furthermore, in the absence of corticoids an extra-pituitary source of ACTH may inhibit adenohypophyseal ACTH synthesis and secretion."

Hodges, J. R., Jones, M. T.: "Some observations on the role of corticosteroids in controlling the adrenocorticotrophic activity

of the pituitary gland." *J. Endocrinol.* **31**: 20-21 (1965). F31,585/65

In rats whose blood corticoid levels were maintained within the physiologic range, stress (sham adrenalectomy) did not diminish the rise in plasma corticosterone or blood ACTH. "Thus it appears that the release of adrenocorticotropic hormone is independent of changes in blood corticoid concentration within the physiological range and that the 'reset' hypothesis is untenable." On the other hand, in adrenalectomized rats, the already high levels of blood ACTH are further increased by a mild stress (ether) that is insufficient to produce a detectable discharge of this hormone in intact animals. The fall in pituitary ACTH caused by adrenalectomy is prevented by replacement therapy with corticoids. Presumably, "a negative feedback mechanism is not of prime importance in regulating pituitary adrenocorticotropic activity. However, corticoids appear to have some function in controlling ACTH secretion."

Corbin, A., Mangili, G., Motta, M., Martini, L.: "Effect of hypothalamic steroid implantations on ACTH feedback mechanisms." *Endocrinology* **76**: 811-818 (1965).

F39,146/65

In rats, dexamethasone and, to a lesser extent, cortisol implants into the ME reduced plasma and adrenal corticosterone levels as well as adrenal weight. Dexamethasone implants into the pituitary cerebral cortex or midbrain periventricular gray proved to be ineffective, but when placed into the midbrain lateral reticular formation they lowered plasma and adrenal corticosterone levels.

Fortier, C.: "Nervous control of ACTH secretion." In: Harris, G. W. and Donovan,

B. T., *The Pituitary Gland*, Vol. 2, pp. 195-234, London: Butterworths, 1966.

J11,292/66

Excellent review on the hypothalamic and limbic control of ACTH secretion, with particular reference to the corticoid feedback mechanisms during stress (more than 300 refs.).

Kawai, A., Yates, R. E.: "Interference with feedback inhibition of adrenocorticotropin release by protein binding of corticosterone." *Endocrinology* **79**: 1040-1046 (1966).

F74,052/66

In rats, intravenous histamine causes nearly maximal ACTH release, as indicated by plasma and adrenal corticosterone content. Unbound corticosterone, given intravenously before histamine, impairs ACTH release, but not if injected in the presence of corticosterone-binding plasma proteins. It is not certain, however, that impairment of the negative feedback action of corticosterone by its binding proteins occurs at low corticosterone concentrations.

Pecile, A., Müller, E.: "Suppressive action of corticosteroids on the secretion of growth hormone." *J. Endocrinol.* **36**: 401-408 (1966).

F74,460/66

In rats, cortisol suppresses not only ACTH but also STH secretion. The latter effect is apparently due to impairment of the release mechanism, as shown by the lack of an STH-releasing response to insulin hypoglycemia.

Feldman, S., Conforti, N., Davidson, J. M.: "Adrenocortical responses in rats with corticosteroid and reserpine implants." *Neuroendocrinology* **1**: 228-239 (1966).

F68,591/66

In rats, dexamethasone or cortisol pellets implanted into the ME inhibited compensatory hypertrophy of the remaining adrenal following unilateral suprarenalectomy. Dexamethasone implants into the pituitary itself caused only slight inhibition. Similar implants of reserpine or subcutaneous injections of the substance could not be shown "to be involved in the negative feedback regulation of ACTH secretion by corticosteroids."

Slusher, M. A., Hyde, J. E., Laufer, M.: "Effect of intracerebral hydrocortisone on unit activity of diencephalon and midbrain in cats." *J. Neurophysiol.* **29**: 157-169 (1966).

G39,577/66

In cats, within ten minutes of intravenous injection of 25 mg. cortisol, "a significant al-

teration in firing rate was seen for the majority of recorded units in hypothalamus and zona incerta. Following intracerebral microinjection of 250 µg. of hydrocortisone into the midbrain, alterations in spontaneous activity of diencephalic units tended to be more delayed than after intravenous injection. Intra-hypothalamic injection was followed by alteration of half of all studied midbrain units within 10 min. The results suggest a reciprocal functional link between the midbrain and the contralateral posterior diencephalon. In addition, neurons in the posterior diencephalon would appear to be more sensitive to local application of hydrocortisone than neurons in the midbrain."

McHugh, P. R., Smith, G. P.: "Negative feedback in adrenocortical response to limbic stimulation in Macaca mulatta." *Am. J. Physiol.* **213**: 1445-1450 (1967).

F92,213/67

In conscious, chair-confined Macaca mulatta, the rise in plasma 17-OHCS following intravenous administration of cortisol was modified by stimulation of certain brain regions with bipolar electrodes. The results furnished "evidence for a negative feedback effect of injected hydrocortisone on the 17-OHCS response to amygdaloid stimulation but not to hypothalamic stimulation and suggest the presence of a neural mechanism for negative feedback located functionally between amygdala and hypothalamus."

Arimura, A., Saito, T., Schally, A. V.: "Assays for corticotropin-releasing factor (CRF) using rats treated with morphine, chlorpromazine, dexamethasone and Nembutal." *Endocrinology* **81**: 235-245 (1967).

F87,059/67

Rats pretreated with chlorpromazine, morphine and Nembutal showed consistently greater rises in plasma corticosterone than those given dexamethasone, morphine and Nembutal upon administration of CRF preparations from rat stalk ME, β -CRF, α -CRF or hypothalamic CRF. "This suggests a direct suppression of the CRF activity by dexamethasone." These and other observations also indicate that chlorpromazine + morphine + Nembutal-treated rats "have many advantages as a new assay preparation for CRF and can be used with greater ease and reliability."

Furukawa, T., Isobe, S., Yano, I.: "The counteraction against the dexamethasone-induced adrenal inhibition by cold stress."

Jap. J. Pharmacol. **17**: 519-524 (1967).
F96,231/67

EM studies on rats show that cold stress can only partially overcome dexamethasone-induced adrenocortical inhibition.

Asfeldt, V. H., Elb, S.: "Hypothalamo-pituitary-adrenal response during major surgical stress." *Acta Endocrinol. (Kh.)* **59**: 67-75 (1968).
H2,076/68

As indicated by the fall in plasma corticosteroids during surgical interventions in man, "suppression by dexamethasone has no influence on the hypothalamic pituitary adrenal response to major acute stress."

Takebe, K., Kunita, H., Sakakura, M., Horiuchi, Y.: "Effect of dexamethasone on ACTH release induced by lysine vasopressin in man; time interval between dexamethasone and vasopressin injection." *J. Clin. Endocrinol. Metab.* **28**: 644-650 (1968).

F98,960/68

Hill, C. D., Singer, B.: "Inhibition of the response to pituitary adrenocorticotropic hormone in the hypophysectomized rat by circulatory corticosterone." *J. Endocrinol.* **42**: 301-309 (1968).
H3,713/68

Experiments on hypophysectomized rats receiving constant infusions of ACTH and corticosterone revealed that the inhibitory effect of the latter on the adrenal response to ACTH can be demonstrated within the gland at plasma corticosterone levels comparable to those found during surgical stress. The earlier literature is cited from which the authors conclude that "the results obtained are compatible with the hypothesis that a feedback mechanism exists at the adrenal level in which corticosterone regulates its own rate of biosynthesis by a primary effect on the rate of synthesis of a regulator protein or some cofactor."

Davidson, J. M., Jones, L. E., Levine, S.: "Feedback regulation of adrenocorticotropin secretion in 'basal' and 'stress' conditions: acute and chronic effects of intrahypothalamic corticoid implantation." *Endocrinology* **82**: 655-663 (1968) (29 refs.).
F97,901/68

Stark, E., Gyévai, A., Ács, Z., Szalay, K. S., Varga, B.: "The site of the blocking action of dexamethasone on ACTH secretion: in vivo and in vitro studies." *Neuroendocrinology* **3**: 275-284 (1968).
H3,331/68

In anesthetized dogs, dexamethasone (200

$\mu\text{g}.$) infused into the hypophysis failed to affect ACTH secretion during the first three hours. Added to a medium of pituitary cells in vitro, dexamethasone was likewise ineffective in altering ACTH secretion. Presumably, "when in contact with hypophyseal cells, dexamethasone has no inhibitory effect on ACTH release in the stressed animal or on the basic ACTH secretion in vitro."

Grimm, Y., Kendall, J. W.: "A study of feedback suppression of ACTH secretion utilizing glucocorticoid implants in the hypothalamus: the comparative effects of cortisol, corticosterone, and their 21-acetates." *Neuroendocrinology* 3: 55-63 (1968).

F97,897/68

In rats, implants of cholesterol into the ME caused no change in the rise of plasma corticosterone following "standard ether stress." Cortisol, corticosterone and their 21-acetates were effective, but the duration of the feedback depended upon their solubility and absorption.

Kendall, J. W., Allen, C.: "Studies on the glucocorticoid feedback control of ACTH secretion." *Endocrinology* 82: 397-405 (1968).

F94,626/68

In intact rats, implants of cortisol in the ME inhibited corticosterone secretion, whereas similar implants in the cerebral cortex were inactive. In contrast, neither implants of cortisol nor even lesions in the ME depressed adrenocortical function in hypophysectomized rats with ten heterotopic pituitaries. Systemically administered dexamethasone suppressed corticoid secretion, even in the latter group. Cortisol implants in the ME caused adrenal atrophy in intact rats, but not in those with heterotopic pituitaries. Hence, "the median eminence may be of importance in feedback regulation of ACTH in intact rats only by virtue of its location at the origin of the pituitary stalk where the hypophyseal blood supply begins." At least the principal site of corticoid feedback appears to be in the pituitary itself.

Bohus, B., Nyakas, C., Lissák, K.: "Involvement of suprahypothalamic structures in the hormonal feedback action of corticosteroids." *Acta Physiol. Acad. Sci. Hung.* 34: 1-8 (1968).

G64,428/68

From observations on rats with cortisol implants in several suprahypothalamic regions, it was "concluded that the hormonal feedback effect of corticosteroids involves various fore- and midbrain areas. It is sug-

gested that the suprahypothalamic corticosteroid-sensitive structures are playing a role in the feedback control of the stress-induced but not of the basal ACTH secretion."

Zimmermann, E., Critchlow, V.: "Negative feedback and pituitary-adrenal function in female rats." *Am. J. Physiol.* 216: 148-155 (1969). H6,475/69

In female rats, 100 $\mu\text{g}/\text{kg}$. of dexamethasone injected subcutaneously at noon suppressed the diurnal variations in plasma corticosterone but not its rise during stress (ether, restraint, handling). Apparently, "it is possible, on the basis of sensitivity to negative feedback, to dissociate mechanisms underlying nonstress pituitary-adrenal function from those which support acute responses to the stresses used in these studies."

Sirett, N. E., Gibbs, F. P.: "Dexamethasone suppression of ACTH release: effect of the interval between steroid administration and the application of stimuli known to release ACTH." *Endocrinology* 85: 355-359 (1969). H15,825/69

Hodges, J. R., Sadow, J.: "Hypothalamo-pituitary-adrenal function in the rat after prolonged treatment with cortisol." *Br. J. Pharmacol.* 36: 489-495 (1969).

G68,229/69

In rats chronically treated with cortisol, the functional activity of the hypothalamo-pituitary-adrenal system gradually recovers after steroid withdrawal, and sensitivity to ACTH returns more rapidly than normal ACTH secretion. Presumably, the transitory impairment of function is due both to reduced responsiveness of the adrenal to ACTH and to failure of the pituitary to discharge this hormone.

Russell, S. M., Dhariwal, A. P. S., McCann, S. M., Yates, F. E.: "Inhibition by dexamethasone of the in vivo pituitary response to corticotrophin-releasing factor (CRF)." *Endocrinology* 85: 512-521 (1969) (41 refs.). H16,365/69

Smelik, P. G.: "The effect of a CRF preparation on ACTH release in rats bearing hypothalamic dexamethasone implants: a study on the 'implantation paradox.'" *Neuroendocrinology* 5: 193-204 (1969). H20,907/69

Ten and eighteen hours after implantation of dexamethasone in the hypothalamus of rats, ACTH secretion could be obtained by CRF but not by vasopressin or other known

releasing stimuli. However, a gradual decrease in pituitary-adrenal responsiveness to CRF was also noted. "It is concluded that the dexamethasone blockade is exerted primarily on the hypothalamic level, but that an eventual transport of the implanted substance to the anterior pituitary may account for the decrease in pituitary sensitivity. However, this could also be due to the absence of endogenous CRF. The sensitivity and specificity of the 10-h dexamethasone-implanted rat would provide a suitable assay preparation for CRF."

Yates, F. E., Brennan, R. D., Urquhart, J.: "Adrenal glucocorticoid control system." *Fed. Proc.* **28**: 71-83 (1969). H7,417/69

Review of contemporary knowledge on the feedback systems regulating inhibition of ACTH, with special reference to computer simulation. It appears that corticoids block adrenal activation by stressors up to a maximum, after which increased severity of the stressor will be effective even in the presence of excess glucocorticoids. "When double dose-response maps of adrenocortical function are made by plotting the response of the adrenocortical system against the strength of the stressful stimulus and obtaining a curve for each condition of corticosteroid pretreatment ranging from none to the maximally effective dose, and beyond, it can be seen that the feedback inhibition property of the adrenocortical system has noncompetitive saturation characteristics. This saturation characteristic explains why many investigators fail to be impressed with the capacity of corticosteroids to inhibit stress response. In those cases in which the failure of inhibition is observed, the strength of the stimulus is very high, and beyond the saturation level for the feedback system. When stimulus strength is lower, however, the feedback inhibition is apparent" (48 refs.).

Dunn, J., Critchlow, V.: "Feedback suppression of 'non-stress' pituitary-adrenal function in rats with forebrain removed." *Neuroendocrinology* **4**: 296-308 (1969).

H14,759/69

In rats, forebrain removal or brain stem transection did not interfere with the suppression of corticoid secretion by dexamethasone, "suggesting that negative feedback acts in part directly on the anterior pituitary." Rats with large hypothalamic islands had unusually high plasma corticosterone levels, whereas those with basal hypothalamic islands, pituitary islands or brain stem transec-

tions maintained their blood corticoids essentially within normal limits.

Dallman, M. F., Yates, F. E.: "Dynamic asymmetries in the corticosteroid feedback path and distribution-metabolism-binding elements of the adrenocortical system." *Ann. N.Y. Acad. Sci.* **156**: 696-721 (1969).

H10,875/69

In rats, "the adrenocortical system appears to have asymmetrical dynamic properties that could qualify it to serve as one channel, or rein, in multiple-channel chemical control arrangements."

Smelik, P. G.: "The regulation of ACTH secretion." *Acta Physiol. Pharmacol. Neerl.* **15**: 123-135 (1969).

G67,350/69

Bohus, B.: "Evaluation of the role of the feedback effect of corticosteroids in the control of pituitary ACTH release." *Acta Physiol. Acad. Sci. Hung.* **35**: 141-148 (1969).

G68,251/69

In rats pretreated with corticosterone, the acute ACTH release caused by restraint or hemidiadrenalectomy remains unaffected, but the action of chronic stressors is suppressed. Sensitivity to exogenous ACTH is unchanged.

Arimura, A., Bowers, C. Y., Schally, A. V., Saito, M., Miller, M. C.: "Effect of corticotropin-releasing factor, dexamethasone and actinomycin D on the release of ACTH from rat pituitaries in vivo and in vitro." *Endocrinology* **85**: 300-311 (1969).

H15,815/69

Comparative in vivo and in vitro studies in rats, using actinomycin D to block DNA-dependent RNA synthesis led the authors to conclude that: "1) Dexamethasone suppresses the action of CRF at the pituitary level, 2) this dexamethasone blockade does not develop immediately, 3) dexamethasone-blockade of CRF requires a process which involves DNA-dependent RNA synthesis, and 4) the process of ACTH release by CRF does not require RNA synthesis" (34 refs.).

H20,906/69

Steiner, F. A., Ruf, K., Akert, K.: "Steroid-sensitive neurones in rat brain: anatomical localization and responses to neurohumours and ACTH." *Brain Res.* **12**: 74-85 (1969).

H28,002/69

Microelectrophoresis allows deposition of minute amounts of soluble compounds in the immediate extracellular environment of single cells in the CNS, and permits direct monitoring of the local response by recording single unit action potentials. In rats, it has been shown with this technique that dexamethasone-sensitive cells can be accurately identified and localized in the hypothalamus and midbrain, scattered over wide areas. The large majority of these cells are clearly inhibited, but some are activated. No steroid-sensitive neurons were found in the cortex, dorsal hypothalamus or thalamus. The steroid-sensitive neurons were responsive to microelectrophoretically applied NEP and acetylcholine. The predominant action of the former was inhibition, while that of the latter was stimulation. ACTH activated the steroid-sensitive neurons. Presumably, "specific nerve cells in the hypothalamus and midbrain are sensitive to both hormonal and humoral factors and involved in negative and positive feedback actions of the hormones."

French, F. S., Macfie, J. A., Williams, T. F., Wyk, J. J. van: "Cushing's syndrome with a paradoxical response to dexamethasone." *Am. J. Med.* **47**: 619-624 (1969).

G70,061/69

In a patient with Cushing's syndrome due to a basophil hypophyseal adenoma, dexamethasone enhanced urinary 17-OHCS and 17-KS excretion as well as plasma ACTH activity. Metyrapone caused an initial rise in urinary 17-KS due to an augmentation of tetrahydro-11-deoxycortisol, as expected, but a much larger increase in adrenal corticoid release occurred on the second and third days and was associated with the reappearance of urinary cortisol metabolites.

Ceresa, F., Angeli, A., Bocuzzi, G., Molino, G.: "Once-a-day neurally stimulated and basal ACTH secretion phases in man and their response to corticoid inhibition." *J. Clin. Endocrinol. Metab.* **29**: 1074-1082 (1969). H15,880/69

In man, submaximal infusion doses of 6-methylprednisolone or dexamethasone led to partial blockade of the nocturnal and early morning urinary 17-OHCS excretion, but no inhibition occurred from 22:00 to midnight unless very massive doses of dexamethasone were administered. It is concluded that "the ACTH-secreting system has 2 daily activity phases with different control mechanisms. One in the nocturnal early morning hours is

the result of neural activity directed to the hypothalamus, superimposed on the basal activity and responsible for the circadian rhythm. This once-a-day impulse would appear to be linked to the rapid eye movement sleep stages. Corticoid-induced inhibition in submaximal doses is possible only during this phase. The second phase is characterized by a steady basal activity lasting 24 hr. It is independent of the early morning hour impulse and is resistant to all but massive doses of corticoids."

Hedge, G. A., Smelik, P. G.: "The action of dexamethasone and vasopressin on hypothalamic CRF production and release." *Neuroendocrinology* **4**: 242-253 (1969).

H14,752/69

In rats, pretreatment with dexamethasone abolished the pituitary-adrenal response to ether or surgical trauma. However, insertion of a cannula into the anterior hypothalamus or injection of vasopressin still elicited transient adrenocortical secretion. Following repeated hypothalamic stimulation or adaptation to handling, subsequent dexamethasone injections had a reduced effect, but the response to CRF preparations remained unchanged. "The data were interpreted to indicate that dexamethasone blocks the production rather than the release of CRF, and that mechanical stimulation of the hypothalamus and vasopressin are able to deplete the CRF stored in the CRF-producing neurons."

Kendall, J. W., Grimm, Y., Shimshak, G.: "Relation of cerebrospinal fluid circulation to the ACTH-suppressing effects of corticosteroid implants in the rat brain." *Endocrinology* **85**: 200-208 (1969). H15,802/69

In rats, pellets of corticosterone or dexamethasone were placed in various regions of the ventricular system, and their effect upon ether-induced ACTH secretion was determined. "It is suggested that reported extra-hypothalamic feedback receptor sites in the rat forebrain can be explained on the basis of transport of corticosteroid from the sites of placement through the ventricular system to a single feedback site located in the basal hypothalamus or anterior pituitary."

Fortier, C., Labrie, F., Pelletier, G., Raynaud, J. P., Ducommun, P., Delgado, A., Labrie, R., Ho-Kim, M.-A.: "Recent studies on the feedback control of ACTH secretion, with particular reference to the role of transcortin in pituitary thyroid-adrenocorti-

cal interactions." In: Wolstenholme, G. E. W. and Knight, J., *Ciba Foundation Symposium on Control Processes in Multicellular Organisms*, pp. 178-209. London: J & A Churchill, 1970. G74,630/70

In rats, thyroxine increases transcartin binding sites and thereby influences the feedback control of ACTH secretion, since the unbound, not the total, corticosterone concentration is the variable factor during this homeostatic reaction. On the other hand, in man, cortisol enhances the effect of thyroxine on transcartin binding, and this multiplies the action of the thyroid hormone upon the corticoid feedback.

Gonzalez-Luque, A., L'age, M., Dhariwal, A. P. S., Yates, F. E. "Stimulation of corticotropin release by corticotropin-releasing factor (CRF) or by vasopressin following intrapituitary infusions in unanesthetized dogs: inhibition of the responses by dexamethasone." *Endocrinology* 86: 1134-1142 (1970) (28 refs.). H25,228/70

Fleischer, N., Rawls, W.: "Adrenocorticotropin (ACTH) synthesis and release in rat pituitary monolayer culture: the effect of dexamethasone." *Clin. Res.* 18: 30 (1970).

H33,211/70

Dexamethasone inhibits the release of ACTH in pituitary monolayers without affecting its synthesis.

Smelik, P. G.: "Adrenocortical feedback control of pituitary adrenal activity." *Prog. Brain Res.* 32: 21-24 (1970).

H45,305/70

Personal observations and review of the literature show that the feedback action of corticoids upon ACTH secretion is primarily on the hypothalamus and to some extent on the pituitary, depending upon dosage, timing and so on. "Such findings may cause some confusion in the literature, because they can be, and have been used, as evidence for or against either a hypothalamic or a pituitary site of action. Only if careful dose and time relationships are established experimentally, it will become clear that the conclusions are dependent on the experimental parameters; and that both structures can be affected, the hypothalamus being the most sensitive one."

Feldman, S., Sarne, Y.: "Effect of cortisol on single cell activity in hypothalamic islands." *Brain Res.* 23: 67-75 (1970).

H45,936/70

In rats with hypothalamic deafferentation (Halász knife), the spontaneous firing of hy-

pothalamic single cell units was increased and could not be diminished by cortisol. "However, when the firing was analysed in individual neurones for longer periods, both before and following cortisol administration, significant changes in the rate and pattern of discharge were found, indicating that the hormone has a direct effect on hypothalamic neurones. The most prominent effect was an initial reduction in the rate of discharge and this may possibly be related to a decrease in corticotropin releasing factor activity produced by corticosteroids at hypothalamic levels."

Feldman, S., Dafny, N.: "Effects of cortisol on unit activity in the hypothalamus of the rat." *Exp. Neurol.* 27: 375-387 (1970).

G76,224/70

In rats, cortisol increased the rate of spontaneous firing in both the anterior-tuberal and posterior hypothalamus. Sciatic stimulation enhanced cell firing in the anterior-tuberal hypothalamus of nontreated rats, while in the cortisol-treated animals, the unit discharge rate was decreased in the anterior-tuberal hypothalamus and increased in the posterior hypothalamus.

Steiner, F. A.: "Effects of ACTH and corticosteroids on single neurons in the hypothalamus." *Prog. Brain Res.* 32: 102-107 (1970).

H45,491/70

By use of a microelectrophoretic application in anesthetized rats, it was found that "dexamethasone phosphate-sensitive neurons were localized in the hypothalamus, and in the midbrain scattered over wide areas. Of these neurons, the large majority was clearly inhibited and a small number activated. No steroid-sensitive neurons were found in the cortex, the dorsal hippocampus, or in the thalamus. Locally delivered synthetic ACTH activated the steroid-sensitive neurons. Noradrenaline and dopamine inhibited, and acetylcholine activated dexamethasone-sensitive neurons. These results could indicate that specific nerve cells in the hypothalamus and midbrain are sensitive to both hormonal and neurohumoural factors."

Bohus, B., Strashimirov, D.: "Localization and specificity of corticosteroid 'feedback receptors' at the hypothalamo-hypophyseal level; comparative effects of various steroids implanted in the median eminence or the anterior pituitary of the rat." *Neuroendocrinology* 6: 197-209 (1970).

H28,814/70

In rats, "suppression of ACTH release was

observed after the implantation of dexamethasone, cortisol, corticosterone, 11-dehydrocorticosterone and 11-deoxycorticosterone (DOC) in the anterior median eminence. 11-Deoxycortisol (Reichstein's substance S), tetrahydrocortisol, pregnenolone, progesterone, and testosterone were ineffective when implanted in this region. Infundibular dexamethasone, cortisol and 11-deoxycorticosterone implants suppressed ACTH release, while other steroids were not effective. Dexamethasone and 11-deoxycorticosterone also suppressed ACTH release when implanted bilaterally in the anterior pituitary." Presumably, corticoid feedback receptors exist in both the hypothalamus and the anterior pituitary.

Fortier, C., Delgado, A., Ducommun, P., Ducommun, S., Dupont, A., Jobin, M., Kraicer, J., MacIntosh-Hardt, B., Marceau, H., Mialhe, P., Mialhe-Voloss, C., Rerup, C., Rees, G. P. van: "Functional interrelationships between the adenohypophysis, thyroid, adrenal cortex and gonads." *Can. Med. Assoc. J.* **103**: 864-874 (1970).

H30,500/70

In the intact rat, thyroxine increases transcartin binding sites. "The unbound, as opposed to total, corticosterone concentration is the variable under feedback control and, in view of the unaltered metabolic clearance rate of corticosterone in the rat, the binding capacity of transcartin is entirely responsible, in this species, for the adjustment of ACTH and corticosterone secretion to altered thyroid activity." The metabolic clearance rate of corticosterone is independent of thyroid activity, because access of the corticoid to inactivation sites in the liver nullifies the enhancement by thyroxine of hepatic-reducing capacity. In man the binding capacity of transcartin is independent of thyroid activity, because cortisol enhances the effect of thyroxine on transcartin binding in proportion to the enhancement by the thyroid hormone of corticoid inactivation.

Bhattacharyya, T. K., Ghosh, A.: "Influence of surgical and steroidical bursectomy on the behavior of adrenal ascorbic acid during stress in juvenile pigeons." *Gen. Comp. Endocrinol.* **15**: 420-424 (1970).

H35,126/70

In juvenile pigeons, bursectomy facilitated the depletion of adrenal ascorbic acid during stress (formalin). Cortisol caused involution of the bursa but left adrenal ascorbic acid levels unaltered after exposure to stress.

Blumenfield, M., Rose, L. I., Richmond, L. H., Beiring, S. C.: "Dexamethasone suppression in basic trainees under stress." *Arch. Gen. Psychiatry* **23**: 299-304 (1970).

G78,353/70

In man, "emotional stress can be a cause for the failure of dexamethasone suppression."

Hodges, J. R., Mitchley, S.: "Circadian rhythm in plasma corticosterone concentration and pituitary adrenocorticotrophic response to stress in the betamethasone treated rat." *Br. J. Pharmacol.* **39**: 192P-193P (1970).

J21,250/70

Hodges, J. R., Mitchley, S.: "The effect of betamethasone on circadian and stress-induced pituitary-adrenocortical function in the rat." *Br. J. Pharmacol.* **38**: 719-724 (1970).

G74,439/70

"Both the circadian and stress-induced changes in plasma corticosterone concentration were abolished by the inclusion of betamethasone in the drinking water of rats." Adrenal sensitivity to ACTH remained unimpaired by betamethasone.

Urquhart, J., Krall, R. L., Li, C. C.: "Adrenocortical secretory function—communications and control aspects." *Automatica* **6**: 193-205 (1970).

J11,823/70

After reviewing their observations on the stimulation of corticoid secretion by ACTH in the canine adrenal, the authors "have developed a seventh order state variable model of this process in terms of current knowledge about the mechanisms of cortisol biosynthesis. The modeling plays a dual heuristic role: (1) at the very least, it provides a phenomenological description of adrenocortical secretory function for use in larger models of pituitary-adrenal control mechanisms, and (2) it is an aid in evaluating postulated mechanisms by which ACTH acts on the kinetic parameters of cortisol biosynthesis."

Takebe, K., Kunita, H., Sakakura, M., Horiuchi, Y., Mashimo, K.: "Suppressive effect of dexamethasone on the rise of CRF activity in the median eminence induced by stress." *Endocrinology* **89**: 1014-1019 (1971).

H47,039/71

In rats, dexamethasone blocked the stress-

induced (surgery) rise in the CRF level of the ME and in the plasma corticosterone concentration. The pituitaries of dexamethasone-treated rats responded to ME extract in a normal manner. It is concluded that the dexamethasone-induced inhibition acts mainly at or above the hypothalamic level.

Hodges, J. R., Mitchley, S.: "Effects of stress and betamethasone on the production of corticosterone by the rat adrenal gland in vitro." *Br. J. Pharmacol.* **41**: 640-647 (1971). G84,324/71

Betamethasone had no effect on glucocorticoid production in vitro when added directly to the incubation medium of previously stressed rats. Presumably, feedback control does not occur at the adrenal level.

Zimmermann, E., Smyrl, R., Critchlow, V.: "Suppression of pituitary-adrenal response to stress with physiological plasma levels of corticosterone in the female rat." *Neuroendocrinology* **10**: 246-256 (1972).

H61,506/72

Small doses of dexamethasone "abolished non-stress pituitary-adrenal function and blocked acute (15 min) corticosterone responses to 1 min ether, 3 min heat, and 1 or 3 min supination, but not those to 3 min ether, immobilization, or cold."

Riegler, G. D., Hess, G. D.: "Chronic and acute dexamethasone suppression of stress activation of the adrenal cortex in young and aged rats." *Neuroendocrinology* **9**: 175-187 (1972). H54,322/72

The corticoid feedback mechanism is much less effective in old than in young rats exposed to ether vapor.

Smellik, P. G.: "Feedback actions of adrenocortical hormones." *Acta Med. Acad. Sci. Hung.* **29**: 89-96 (1972). J10,356/72

Review of the literature and personal observations suggest that hypothalamic centers exert a tonic influence on ACTH secretion and also regulate its rhythmic circadian variations and increased release during stress. Activation of the system can be suppressed by corticoids through a feedback in the hypothalamus, "presumably located in the cell bodies of the CRF neurons. These neurons are capable of summing excitatory and inhibitory stimuli, which can be either neural or humoral and after summation they will send a releasing signal of an exactly determined intensity to the anterior pituitary." Sayers' theory that increased utilization of corticoids during stress is re-

sponsible for an effective feedback to inhibit further ACTH secretions is rejected, since it was based on an "incorrect assumption, i.e., that stress would cause an initial fall in corticoid levels. As soon as direct measurement of corticoid titers could be performed, it appeared that such an initial fall does not take place."

Ondo, J. G., Kitay, J. I.: "Effects of dexamethasone and stressful stimuli on hypothalamic electrical activity in rats with diencephalic islands." *Neuroendocrinology* **9**: 215-227 (1972). H56,043/72

In rats with diencephalic islands (Cross and Kitay technique), dexamethasone was shown to have a direct effect on the neurons of the isolated basal hypothalamus. However, vasopressin and histamine, which have an inverse effect on ACTH discharge, similarly inhibited the firing of hypothalamic neurons. Thus, "a simple explanation relating neuronal firing rate and the mechanisms involved in the control of ACTH secretion is obviously not possible." The literature on the effects of various hormones on hypothalamic neurons is reviewed.

Papaikonomou, E.: "A cybernetic approach to the hypothalamo-pituitary/adrenal system." *Prog. Brain Res.* **38**: 293-302 (1972).

J11,299/72

Brief summary of the author's mathematical approach to the cybernetic regulation of the hypothalamus-pituitary-adrenal feedback system.

Endrőczi, E.: "Role of glucocorticoids in controlling pituitary-adrenal function." *Acta Med. Acad. Sci. Hung.* **29**: 49-59 (1972) (23 refs.).

Wittkowski, W., Bock, R.: "Electron microscopical studies of the median eminence following interference with the feedback system anterior pituitary-adrenal cortex." In: Knigge, K. M., Scott, D. E. et al., *Brain-Endocrine Interaction. Median Eminence: Structure and Function*, pp. 171-180. Basel and New York: S Karger, 1972.

E10,567/72

EM studies on the ME in adrenalectomized or cortisol-treated rats illustrate the structural basis of the feedback mechanism. The diameter of "Gomori-positive" elementary granules in the zona externa is variable but never attains that of the granules in the zona interna. The "findings support the assumption that different hormones and their carrier substances are concerned—oxytocin and vasopressin in the zona interna and the CRF in the zona externa."

Kraicer, J., Gosbee, J. L., Bencosme, S. A.: "Pars intermedia and pars distalis: two sites of ACTH production in the rat hypophysis." *Neuroendocrinology* **11**: 156-176 (1973). H68,125/73

In rats "the concentration of ACTH in the pars intermedia is considerably greater than that in the pars distalis. At 1 month after adrenalectomy, the ACTH concentration in the pars distalis increased 3-fold, while that in the pars intermedia remained unchanged. Following chronic administration of cortisol, the ACTH concentration in the pars distalis fell to 27% of the control, while the fall in ACTH concentration in the pars intermedia was not significant.... Although a relation between the pars intermedia and ACTH is established, this relation is different from that between the pars distalis and ACTH."

Dallman, M. F., Jones, M. T.: "Corticosteroid feedback control of stress-induced ACTH secretion." In: Brodish, A. and Redgate, E. S., *Brain-Pituitary-Adrenal Interrelationships*, pp. 176-196. Basel, München and Paris: S Karger, 1973. J11,222/73

In rats "the net result of both stress and corticosterone feedback signals is a continually responsive system that does not secrete too much ACTH but always secretes enough. Acutely, the rise of corticosterone stimulated by increased ACTH levels acts through a rate-sensitive or fast-feedback path to rapidly limit the duration of ACTH

secretion; and chronically, two or more hours after corticosterone levels have been elevated there is a decrease in the amount of ACTH secreted in response to stress. Stress itself, however, appears to facilitate the response of some element of the adrenocortical system above the adrenal to subsequent stress."

Smelik, P. G., Papaikonomou, E.: "Steroid feedback mechanisms in pituitary-adrenal function." *Prog. Brain Res.* **39**: 99-109 (1973). J11,300/73

Analysis of the pituitary-hypothalamus system in terms of a feedback loop. "The system does not operate with a fixed or variable set-point, but should be considered as a servomechanism, which follows the variable needs for glucocorticoids. The amount of CRF released depends on a summation by a hypothalamic comparator of neural and humoral stimuli, which can be positive or negative." The capacity of the feedback signal is limited and has only a stabilizing function. There is no qualitative difference between the basal state of the system and its response to stress. [In the discussion Hodges states, "in spite of the work which Dr. Smelik has presented, I still believe that while corticosteroids may control the basal level of ACTH secretion and corticotrophin synthesis, a feedback mechanism controlling stress-induced ACTH secretion is of little physiological significance" (H.S.).]

Goldman, L., Winget, C., Hollingshead, G. W., Levine, S.: "Postweaning development of negative feedback in the pituitary-adrenal system of the rat." *Neuroendocrinology* **12**: 199-211 (1973). H74,726/73

Given before ether or electroshock, "pretreatment with peripherally injected dexamethasone completely blocked a plasma corticosterone increase, in response to an ether and blood sampling stress in adults, but only partially reduced this response in weanlings. The failure of basal hypothalamic implants of corticoids to differentiate between ages in their ability to inhibit this stress response supported the suggestion of extra-hypothalamic inhibitory systems as the loci of the deficit in weanlings."

Kraulis, I., Traikov, H., Li, M. P., Birmingham, M. K.: "The effects of corticosterone, 18-OH-DOC, DOC and 11 β -hydroxyprogesterone on the adrenal pituitary axis of the stressed rat." *J. Steroid Biochem.* **4**: 129-137 (1973). J2,229/73

Progesterone and 18-OH-DOC, unlike corticosterone, 11 β -hydroxyprogesterone, and DOC, failed to inhibit the ACTH discharge in rats stressed either with ether or by a change of environment.

Langholz, J., L'age, M.: "Disturbance of the feedback mechanism of the adrenocortical system in the alloxan diabetic rat." *Acta Endocrinol.* (Kbh.) **72** Supp. 171: 31 (1973). H68,831/73

Dallman, M. F., Jones, M. T.: "Corticosteroid feedback control of ACTH secretion: effect of stress-induced corticosterone secretion on subsequent stress responses in the rat." *Endocrinology* **92**: 1367-1375 (1973). H70,213/73

The authors conclude from their experiments and a survey of the literature that in adrenalectomized rats "corticosterone does act to inhibit ACTH secretion, but that stress causes a prolonged period of hyper-responsiveness in either CNS or anterior pituitary components of the adrenocortical system."

Briaud, B.: "Réponse corticosurrénalienne aux agressions neurotropes et systémiques après injection de corticostéroïdes" (Adrenocortical response to neurotropic and systemic stress after corticosteroid injection). *J. Physiol.* (Paris) **66**: 259-270 (1973). J7,439/73

In rats, about twice as much corticosterone or dexamethasone is needed to inhibit the adrenal response to systemic (ether) than to neurogenic (sound) stress of equal intensity.

Melby, J. C.: "Systemic corticosteroid therapy: pharmacology and endocrinologic considerations." *Ann. Intern. Med.* **81**: 505-512 (1974). J16,876/74

In patients with rheumatoid arthritis, pyrogen therapy was often superior to treatment with glucocorticoids. "High-dose corticosteroid therapy abolished the hypothalamic-pituitary-adrenal response to pyrogen stress, whereas low doses of steroids produced only insignificant alterations to the response to pyrogen stress. Other studies involving testing of the negative feedback response (metyrapone test) may be abnormal even at rather modest doses of corticosteroids."

Buckingham, J. C., Hodges, J. R.: "Interrelationships of pituitary and plasma corticotrophin and plasma corticosterone in adrenalectomized and stressed, adrenalectomized rats." *J. Endocrinol.* **63**: 213-222 (1974). H95,881/74

Experiments on rats exposed to ether vapor "suggest that the synthesis and the basal release of ACTH are directly controlled by the concentration of corticosteroid in the blood, but the corticosteroids exert only a delayed effect in modulating the stress-induced release of the hormone."

Zurbrügg, R. P., Zimmermann, E., Oetliker, O. H.: "Adrenocortical function following long-term corticosteroid treatment." *Helv. Paediatr. Acta* **29**: 221-235 (1974).

J16,948/74

In patients on chronic prednisone therapy, ACTH discharge during stress or injection of ACTH causes subnormal glucocorticoid secretion, even several weeks after discontinuation of treatment (82 refs.).

Turner, B. B., Taylor, A. N.: "Neonatal corticosterone treatment: persistence of reduced corticosteroid levels in adult rats." *Fed. Proc.* **33**: 206 (1974). H83,817/74

In rats, implantation of corticosterone pellets during the first three weeks of life may exert a permanent suppressive effect upon adrenal corticoid production, detectable after they become adults.

Mitro, A., Németh, S., Mikulaj, L.: "Inhibition of the adrenal response to various stressors by hydrocortisone administration into the brain ventricles." *Gen. Comp. Endocrinol.* **22**: 361 (1974). H83,191/74

Buckingham, J., Hodges, J. R.: "Corticosterone in the control of corticotrophin secretion in the rat." *J. Endocrinol.* **61**: xxvi-xxvii (1974). H87,553/74

Experiments on intact and adrenalectomized rats treated with corticosterone and exposed to the stressor effect of mild ether anesthesia "suggest that, under 'normal' physiological conditions, blood corticosteroids are involved in the control of the basal secretion of ACTH but that they do not affect the stress-induced release of the hormone."

Jones, M. T., Tiptaft, E. M., Brush, F. R., Fergusson, D. A. N., Neame, R. L. B.: "Evidence for dual corticosteroid-receptor mechanisms in the feedback control of adrenocorticotrophin secretion." *J. Endocrinol.* **60**: 223-233 (1974). H83,403/74

In rats, fast feedback of ACTH secretion during surgically induced stress occurs within minutes of treatment with small doses of corticosterone but is of short duration. Delayed feedback occurs after 1 hour or more,

and requires larger doses of corticosterone. The latter and cortisol are synergists in both these feedbacks, whereas DOC and 11-desoxycortisol are antagonists of fast and agonists of delayed feedback. "It is concluded that the two feedback mechanisms have different dynamics and separate receptors."

Brush, F. R., Dallman, M., Jones, M. T., Tiptaft, E.: "Corticosteroid feedback at the pituitary level." *J. Endocrinol.* 61: lxiv-lxv (1974). H87,801/74

ACTH secretion is regulated by both a fast and a delayed corticoid feedback. From corticosterone production in the adrenals of ME-lesioned rats, it is concluded that "delayed corticosteroid feedback exists at both the hypothalamic and pituitary levels, but that some corticosteroids feedback exclusively at the hypothalamus."

Chattopadhyay, S., Uniyal, M.: "The interaction of stress and corticosteroid on the hypothalamus as reflected by GABA content." *5th Asia & Oceania Congr. Endocr.*, p. 48. Chandigarh, India, 1974. H82,064/74

In rats the negative feedback influence of circulating corticosteroids and the administration of triamcinolone induced a low GABA concentration in the hypothalamus, whereas exposure to stress led to a higher GABA level than in the controls. "The interaction of stress-induced excitation and negative feedback inhibition owing to increased concentration of corticosteroid may involve GABA in the integrative processes of the hypothalamus."

Daly, J. R., Fleisher, M. R., Chambers, D. J., Bitensky, L., Chayen, J.: "Application of the cytochemical bioassay for corticotrophin to clinical and physiological studies in man." *Clin. Endocrinol. (Oxf.)* 3: 335-345 (1974).

H88,166/74

In rheumatoid arthritics chronically treated with ACTH, insulin hypoglycemia causes a subnormal rise in plasma ACTH, yet the plasma cortisol level is identical to that in the controls. Presumably, the adrenal in ACTH-treated patients is hypersensitive and responds to subnormal amounts of ACTH with an enhanced cortisol secretion. However, the difference is very slight, and only the rate of response, measured by the slope of the steepest part of the curve, differs significantly. Hence, strong ACTH treatment alters only the rate of ACTH release in response to hypoglycemia, not the total amount

secreted. In contrast, prolonged corticoid treatment greatly reduces the ACTH discharge following insulin hypoglycemia.

Buckingham, J. C., Hodges, J. R.: "The redox bioassay technique for the direct assessment of pituitary adrenocorticotrophic activity in the rat." *Clin. Endocrinol. (Oxf.)* 3: 347-348 (1974). H88,167/74

The rise in plasma and pituitary ACTH that occurs after adrenalectomy or adrenalenucleation in rats is inversely correlated with plasma corticosterone levels, but the elevation after mild stress (ether anesthesia) is not. "It appears that under 'normal' physiological conditions the blood corticosteroids are involved in the control of both the synthesis and the basal secretion of ACTH but that they do not affect the stress induced release of the hormone."

Papaikonomou, E.: *Biocybernetics, Bio-systems Analysis and the Pituitary Adrenal System*, p. 334. Purmerend, Netherlands: Nooy's Drukkerij, 1974. E10,437/74

A monograph that combines insight and wit in applying the principles of systems analysis strategy and biocybernetics to the study of the pituitary-adrenocortical apparatus in relation to the G. A. S. Sayers' hypothesis about the activation of ACTH secretion by a negative feedback due to increased utilization of glucocorticoids during stress was not supported by subsequent experiments. It was replaced by Yates' theory that stress activates a controller of the system in the hypothalamus. Then Smelik provided evidence of an integral controller of the system with a derivative controller sensitive to negative rates of change of blood glucocorticoids. In studies concerning the regulation of corticoid secretion, it is essential to consider the ACTH concentration of the blood, and the flow, as separate input variables, and to distinguish between the effect of free and protein-bound corticoids. The author summarizes his concept as follows: "At the lowest level we put the anterior pituitary (adenohypophysis) [and the adrenal cortex], along with local metabolic regulators in peripheral tissues and organs, which are under the control of glucocorticoids. Under normal (non-stress) conditions there will be an optimal activity pattern for this level with a corresponding optimal set of characteristics and parameters of its elements; these are established during postnatal development."

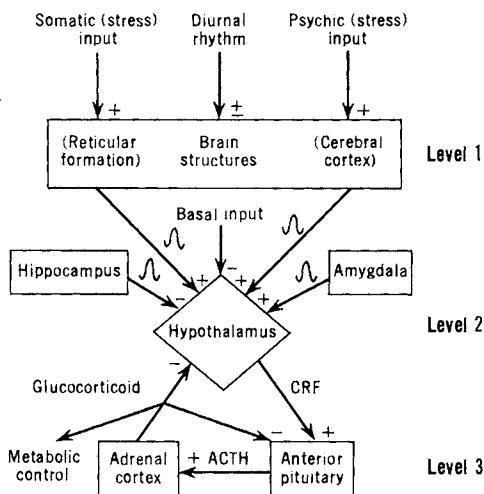

Figure 21. A three-level model of communication and control hierarchy in the pituitary adrenal system. (Reproduced from *Biocybernetics, Biosystems Analysis, and the Pituitary Adrenal System* (1974), Fig. 6-8, p. 170, by permission of E. Papaikonomou and Nooy's Drukkerij.)

"A feature of autoregulation is exhibited here by means of the DBM elements (distribution, binding, and metabolism, not shown in the scheme), and by the mildly modulating (inhibitory) effect of glucocorticoids on the pituitary response to CRF. Since this activity will have to be constant as long as nothing changes at the lowest level, (this is a corollary of the hypothesis of homeostasis of Claude Bernard), the only thing needed for the resting function of this level is a constant stimulus from a higher level; apart from this constant stimulus, the lowest level is virtually autonomously functioning.

"At the second level there is the hypothalamus from which the command signal to the lowest level originates, along with two other brain structures, the amygdala and the hippocampus (the first with an excitatory and the second with an inhibitory action on the hypothalamus; it should be noted that this may be an oversimplification: Some other brain structures like the midbrain and the thalamus may also be involved). We actually distinguish two sublevels in this second level of control: the hypothalamus lower, the amygdala and the hippocampus higher. When something happens in the lowest level, (e.g., some metabolic change, external disturbance of ACTH or glucocorticoid levels by injection, etc.), then the CRF command signal

(output of the hypothalamus) changes accordingly to counteract the deviations; these deviations are, of course, monitored at the second level ("feedback" of glucocorticoids); if they are not too big by the hypothalamus, but if they are extreme also by the amygdala and the hippocampus. Here information about the deviations is integrated with information from other parts of the organism (tissues or other homeostatic mechanisms), and the resulting control signal is sent forward to the lowest level.

"Finally, when an external stimulus such as *psychic stress* (e.g., anxiety, fear, a new environment, etc.), or *somatic stress* (e.g., trauma, surgery, noxious substances, etc.), appears, which brings the whole organism in danger, then the highest control level comes into action. We think that at this level are the cerebral cortex (monitoring psychic stress) and the brain stress reticular formation (where somatic stress is monitored); some other structures intervening between the above ones and the second level structures may also be actively involved. Information about the stimulus is here correlated and integrated with stored information about the consequences of similar stimuli in the past and a control action is taken to increase (never decrease) the activity of the lowest level; this will take place by first changing

the activity of the second level, which will then result in an amplification of the output of this level, the CRF signal. This signal shows under resting conditions a diurnal oscillation (correlated with the sleep-and-wake schedule) that probably is generated at the highest control level" (about 450 refs.).

Feldman, S., Conforti, N., Chowers, I.: "Effect of dexamethasone on adrenocortical responses in intact and hypothalamically deafferented rats." *Isr. J. Med. Sci.* **10**: 572 (1974). H89,689/74

Inhibition of ACTH secretion by dexamethasone is more pronounced in intact than in hypothalamically deafferented rats. Apparently, the negative feedback of corticoids is exerted at the hypothalamic level, but

extrahypothalamic structures also participate in it.

Vermesh, I., Ryzhenkov, V. E.: "Functional condition of the hypophysis-adrenal system in rats with deafferented hypothalamus; the action of dexamethasone and nialamide." *Probl. Endokrinol.* **20** No. 3: 67-70 (1974) (Russian). H92,315/74

In rats with a completely deafferented MBH, the basal plasma corticosterone level rose; this elevation could be inhibited by dexamethasone or nialamide. "At the same time suppression of corticosterone secretion in stress [restraint] by nialamide was stronger in comparison with dexamethasone. Nialamide potentiated the depressive action of dexamethasone on the basal corticosterone secretion, but not under stress."

Corticoid "Utilization"

Some data concerning the "utilization" theory of corticoids as a means of regulating their production during stress have been discussed in the previous section, Corticoid Feedback; for the sake of completeness, these should also be consulted.

The question whether hormones are actually consumed by their receptors during the performance of their roles or act merely by their presence (as catalysts do) remains unsettled. However, beginning some twenty-five years ago, Sayers and his co-workers published a large number of papers in support of the concept that corticoid production increases during stress as a consequence of diminished feedback-inhibition of ACTH secretion, because the tissue utilization of corticoids rises. Yet as early as 1948 we showed that even enormous anesthetic doses of DOC failed to prevent the decrease in adrenal ascorbic acid content following exposure to cold. Hence we concluded that mere lack of corticoids could not be the decisive factor eliciting an ACTH discharge during stress.

It is hardly necessary today to reexamine all the arguments mustered in favor of the corticoid "utilization" theory, which held that "the tissues of the organism with a normal pituitary-adrenal system are never subjected to a plethora of cortical hormones as implied in the 'diseases of adaptation' thesis of Selye." If it were true that the feedback mechanism works perfectly during stress, the latter could never induce an increase in corticoid production, which it undoubtedly does. The complex theories and schematic drawings that attempted to coordinate increased corticoid utilization with nervous and catecholamine-regulated stimulation of ACTH secretion are listed in the abstract section merely for historical reasons, because they gave rise to a very large number of publications that the uninitiated worker in this field might otherwise be unable to evaluate.

The most significant fact to remember is that the corticoid feedback mechanism, though extremely important for homeostasis during near-physiologic conditions, becomes ineffective precisely during stress. This failure is of the greatest importance for the maintenance of homeostasis, since an adaptive increase in corticoid production would be impossible if the feedback mechanism continued to function perfectly, thus

interfering with the provision of an excess of corticoids at times of stress, when normal amounts are clearly insufficient.

It might have been argued that DOC, even in doses high enough to produce anesthesia, is not as potent as glucocorticoids in inhibiting ACTH secretion during stress. However, we found that even toxic doses of exogenous glucocorticoids (for example, cortisone) or endogenous steroids of this type (cortisol, corticosterone), secreted during stress, fail to prevent the ACTH discharge characteristic of the alarm reaction. Hence, the theory that a depletion of corticoids, owing to increased utilization, could explain the stress-induced ACTH discharge has by now been generally rejected.

If further arguments were needed, it might be mentioned that intravenous cortisol is less rapidly cleared from the blood in man during surgical stress than otherwise. Presumably, blood clearance of the hormone not only fails to be enhanced because of increased utilization but is actually delayed. Furthermore, in adrenalectomized dogs, the eosinopenic effect of cortisol is augmented by surgical interventions. "These and other data throw doubt on the hypothesis that increased corticoid utilization is responsible for the pituitary release of ACTH in the response to operative trauma." Finally, adrenalectomized animals are particularly sensitive to the ACTH-discharging effect of stressors, although they have no corticoids to start with and hence could not consume them during stress.

Corticoid "Utilization"

(See also our earlier stress monographs, p. xiii)

Sayers, G., Sayers, M. A.: "Regulation of pituitary adrenocorticotrophic activity during the response of the rat to acute stress." *Endocrinology* 40: 265-273 (1947).

98,805/47

In rats, various stressors (heat, cold, histamine, EP, bacterial toxins and so on) fail to stimulate the adrenal cortex if sufficient amounts of glucocorticoids are supplied (as indicated by adrenal ascorbic acid content). "It would appear reasonable to suppose that the great variety of non-specific stresses increases pituitary adrenocorticotrophic activity by a common mechanism, namely, by increasing the requirement of the peripheral tissue cells for cortical hormone(s)."

Moya, F., Selye, H.: "Effect of desoxycorticosterone upon hypophyseal corticotrophin production." *Proc. Soc. Exp. Biol. Med.* 68: 529-531 (1948). B19,381/48

Even enormous anesthetic doses of DOC cannot prevent the decrease in adrenal ascorbic acid content following exposure to

cold. Hence, mere lack of corticoids cannot be the decisive cause of ACTH discharge during stress.

Sayers, G.: "Pituitary regulation of adrenal cortical activity." In: Soskin, S., *Progress in Clinical Endocrinology*, pp. 122-130. New York: Grune & Stratton, 1950.

B47,555/50

The author recapitulates his arguments in favor of enhanced "utilization" of corticoids during stress that would prevent the development of diseases of adaptation, owing to conditioning that increases sensitivity to pathogens. "It appears that the tissues of the organism with a normal pituitary-adrenal system are never subjected to a plethora of cortical hormones as is implied in the 'diseases of adaptation' thesis of Selye" (26 refs.).

Sayers, G.: "The adrenal cortex and homeostasis." *Physiol. Rev.* 30: 241-320 (1950).

B49,880/50

Extensive review of the literature on factors regulating corticoid production during stress. It is stated that stressors can increase the "utilization" of corticoids and might act as a feedback system, in that the resulting state of hypocorticism would stimulate ACTH secretion. Special sections are devoted to indices of the rate of corticoid discharge, the different types of corti-

coids, the G. A. S., the diseases of adaptation and so on (519 refs.).

McDermott, W. V., Fry, E. G., Brobeck, J. R., Long, C. N. H.: "Mechanism of control of adrenocorticotropic hormone." *Yale J. Biol. Med.* **23**: 52-66 (1950).

B51,980/50

Experiments on rats led to the concept that ACTH discharge during stress proceeds in two relatively independent and sequential phases. "The first or autonomic phase depends on the reflex secretion of epinephrine which directly activates the anterior pituitary, while the second or metabolic phase is based upon the rate of utilization of adrenal cortical hormones within the organism."

Hall, C. E., Finerty, J. C., Hall, O., Hess, M.: "The effect of acute and chronic desoxycorticosterone acetate pretreatment on the pituitary-adrenal response to stress." *Endocrinology* **48**: 591-595 (1951).

B59,640/51

Neither acute treatment with anesthetic doses of DOC nor chronic administration of smaller doses of the steroid affects adrenal ascorbic acid concentration. Such dosages also fail to prevent the characteristic stress response to burns. These findings are incompatible with the "corticoid utilization" theory of ACTH stimulation during stress.

Sayers, G.: "Regulation of the secretory activity of the adrenal cortex." *Am. J. Med.* **10**: 539-548 (1951).

B58,574/51

Review of the author's interpretation of corticoid secretion during stress. "In severe stress, anoxia or toxins may act directly on the adenohypophysis to induce discharge of ACTH. The fact that adenohypophyseal transplants discharge ACTH in response to stress indicates that direct neural or neurovascular connections are not essential elements in the regulatory scheme." It is primarily the increased "utilization" of corticoids during stress that causes a state of relative hypocorticism, stimulating ACTH secretion. "The concept emphasizes the determining role which the peripheral tissues, by their rate of 'utilization' of cortical hormone, exert in regulating pituitary adrenocorticotropic activity." The distinction between glucocorticoids and mineralocorticoids is rejected because it "implies that the secretion of the adrenal cortex may vary in composition according to the requirements of the organism." The findings reported by other laboratories that corticoids cannot

produce stress-induced adrenal ascorbic acid depletion may be explained by assuming that the "rate of 'utilization' of cortical hormone appears to be exceedingly fast during severe stress." Even "epinephrine may act like other non-specific agents and stresses to increase tissue 'utilization' of cortical hormone with a consequent lowering of venous blood titer of the hormone." Since transplants of adenohypophysis into the anterior chamber of the eye discharge ACTH during stress, "it appears that neither direct neural nor neurovascular connections with the hypothalamus are essential for the discharge of ACTH from the adenohypophysis" (86 refs.). [See later abstracts; virtually every one of these conclusions has since been contradicted (H.S.).]

Sayers, G.: "Regulation of pituitary corticotropin activity." In: Ralli, E. P., *Adrenal Cortex*, pp. 48-87. New York: Josiah Macy Jr. Foundation, 1951.

B60,495/51

In rats, manipulation of the intestines causes increased corticoid secretion (blood eosinophil test) in one hour, with it reaching a maximum in four hours. Following adrenal demedullation, suitable placement of lesions in the diencephalon, or transection of the spinal cord at the level of the third dorsal vertebra, this reaction still occurs but is greatly delayed. "We interpret this to mean that the reflex pathway for the secretion of epinephrine has been interrupted either by demedullation of the adrenals or by destruction of the ganglia in the brain stem that are concerned with this reflex." Presumably, the discharge of EP merely reinforces the ACTH-releasing mechanism. The most important regulator of ACTH is the blood level of corticoids, which drops during stress because of increased "utilization" by the tissues. Transection of the infundibulum does not interfere with the response of the pituitary to acute stress, as shown by many previous investigators; therefore, direct neural connections between the gland and the hypothalamus are not necessary, but this does not rule out messages transmitted through the hypophyseal portal system. The author believes that the work of several among his predecessors has shown conclusively that the fact "that adenohypophyseal transplants discharge ACTH in response to stress indicates that direct neural or neurovascular connections are not essential elements in the regulatory scheme. However, the experiments do not rule out the possibility that the hypothalamus has a modifying influence upon

pituitary adrenocorticotrophic activity." The literature on the inhibition of stress-induced ACTH discharge by DOC and cortisone is reviewed and confirmed, although the blockade is not complete and can be broken through by very severe stress. In the discussion of this paper, Selye confirms that such experiments have been performed at his institute, but still emphasizes that "the important point, however, is that there must be a mechanism, other than the level of circulating corticoids, which regulates ACTH discharge during stress. Otherwise, it would be impossible to understand how such an ACTH discharge could be effected in the presence of overwhelmingly large amounts of exogenous corticoids" (68 refs.).

Fortier, C., Yrarrazaval, S., Selye, H.: "Limitations of the ACTH regulating effect of corticoids." *Am. J. Physiol.* **165**: 466-468 (1951). B53,351/51

Even very large doses of cortisone given subcutaneously or intraperitoneally "failed to prevent or even to significantly decrease the adrenal ascorbic acid depletion resulting from various types of severe stress. These results show that ACTH release in response to stress is compatible with a high level of circulating corticoids and that hypocorticoidism is not the sole responsible agent of the activation of the adrenocorticotrophic function."

Sandberg, A. A., Eik-Nes, K., Samuels, L. T., Tyler, F. H.: "The effects of surgery on the blood levels and metabolism of 17-hydroxycorticosteroids in man." *J. Clin. Invest.* **33**: 1509-1516 (1954). B99,413/54

In man, surgery causes a rapid increase in plasma 17-OHCS within the first hour. Intravenous cortisol is not cleared from the blood as rapidly during surgical stress as otherwise. Presumably, not only increased corticoid secretion but also decreased clearance contribute to the raised blood corticoid levels.

Cowie, A. T., Ganong, W. F., Hume, D. M.: "The eosinopenic response to graded doses of hydrocortisone in the adrenalectomized dog with and without surgical trauma." *Endocrinology* **55**: 745-750 (1954). C264/54

The eosinopenic effect of low doses of cortisol is enhanced by surgical trauma, even in adrenalectomized dogs. "These and other data throw doubt on the hypothesis that increased corticoid utilization is responsible for

the pituitary release of ACTH in response to operative trauma."

Ulrich, F., Long, C. N. H.: "Effects of stress on serum C¹⁴ levels in rats following administration of hydrocortisone-4-C¹⁴ and corticosterone-4-C^{14".} *Endocrinology* **59**: 170-180 (1956). C22,143/56

"Although little, if any, positive evidence was found to substantiate the concept of increased peripheral utilization of adrenocortical hormones during stress, the evidence obtained from these experiments would seem to warrant a conclusion of 'not proven' as regards this theory."

Eik-Nes, K. B., Samuels, L. T.: "Metabolism of cortisol in normal and 'stressed' dogs." *Endocrinology* **63**: 82-88 (1958).

C55,691/58

In dogs exposed to various stressors, the blood clearance of intravenous injections of cortisol is normal or even delayed. "Mechanisms other than increased 'utilization' of adrenal steroids might therefore be responsible for augmented ACTH secretion in conditions of 'stress'."

Ingle, D. J., Ingle, D. J.: "The relationship of the adrenal glands to diseases of adaptation." *Acta Endocrinol. (Kh.)* **50** Supp.: 89-92 (1960). C92,395/60

Recapitulation of the authors' experiments on the permissive (conditioning) action of glucocorticoids. The production of diseases of adaptation by excess corticoid secretion during stress is questioned on the basis of the assumption that, under stress, more corticoids are utilized for resistance, which is also why Cushingoid symptoms do not occur. Still, the authors admit that some symptoms of corticoid excess are evident during stress. They conclude that "suppression of some but not all symptoms of hypercorticalism by stressors may be related to the well known fact that the need of the organism for cortical hormones is greatly increased by severe stress." [It is difficult to see how removal of excess corticoids by enhanced utilization could selectively annul only some of their effects (H.S.).]

Ingle, D. J., Young, S.: "Effect of cortisone acetate and of certain stressors on blood pressure and on the pathology of heart and kidney in uninephrectomized male rats." *Endocrinology* **70**: 806-814 (1962).

D25,297/62

Stressors (formaldehyde, bone fractures)

"did not block the loss of weight or the regression of thymus and spleen in rats overdosed with cortisone."

Smelik, P. G.: "Relation between blood level of corticoids and their inhibiting effect on the hypophyseal stress response." *Proc. Soc. Exp. Biol. Med.* **113**: 616-619 (1963).

E21,483/63

In rats, large subcutaneous doses of corticosterone suppressed adrenal corticoid production in vitro following exposure to stress in vivo, but there was no parallelism between this inhibition and the plasma corticosterone levels. "It is concluded that pituitary impairment by corticoid administration is not correlated with the existing blood level of corticoids."

Deckx, R., Moor, P. de, Denef, C., Raus, J.: "Effect of adrenalectomy, sham operation or ACTH on the cortisol metabolizing enzymes of rat liver homogenate." *Metabolism* **14**: 264-270 (1965). F32,028/65

In female rats, the direct effect of ACTH on the metabolism of cortisol by liver homogenate differs from that of stress. These circumstances may explain the many apparent contradictions concerning the effect of stress upon the overall rate of corticoid metabolism (21 refs.).

Estep, H. L., Litchfield, D. L., Taylor, J. P., Tucker, H. S. G. Jr.: "Acute effect of traumatic stress on cortisol metabolism in man." *J. Clin. Endocrinol. Metab.* **26**: 513-517 (1966). F66,349/66

"Plasma disappearance rates of 4-¹⁴C-cor-

tisol or unlabeled cortisol, or both, were measured in relatively healthy patients before and again during laparotomy. The biologic half-time of labeled cortisol during surgery was unchanged or decreased slightly from the control value." A slight delay in the removal of exogenous cortisol during stress may be partly explained as the consequence of increased adrenal secretion and elevated plasma levels of endogenous cortisol.

Panaretto, B. A., Vickery, M. R.: "The rates of plasma cortisol entry and clearance in sheep before and during their exposure to a cold, wet environment." *J. Endocrinol.* **47**: 273-285 (1970). H28,932/70

In sheep exposed to cold, "decreased cortisol clearance rates did not appear to contribute to the great increases in plasma concentration until rectal temperature was about 34°." Curiously, the adrenal cortex and liver of the sheep were heavily infiltrated with fat after severe hypothermia.

Courtney, G. A., Marotta, S. F.: "Adrenocortical steroids during acute exposure to environmental stresses: I. Disappearance of infused cortisol." *Aerosp. Med.* **43**: 46-51 (1972). J20,019/72

Courtney, G. A., Marotta, F.: "II. Uptake and release of infused cortisol by the hind limb of dogs." *Aerosp. Med.* **43**: 52-55 (1972). J20,018/72

In dogs, the disappearance rate of infused cortisol was not very consistently affected by a variety of stressors.

Transcortin

Most of the actions of corticoids are masked when the steroids are bound to carriers. This phenomenon has been touched upon briefly in the section on the Corticoid Feedback mechanism, since ability to inhibit ACTH secretion is also limited to free corticoids.

It is important, therefore, that corticoids, as many other steroid hormones, are primarily carried in the blood as conjugates bound to plasma proteins (especially globulin). One of these proteins, which has a particularly high affinity for cortisol, has been named transcortin. It is thought to bind cortisol and corticosterone at different sites on its molecule. Other hormonal steroids are bound to transcortin only weakly or not at all. It is only when the blood cortisol concentration exceeds transcortin capacity that marked physiologic effects appear (for example, during stress or after ACTH administration).

Comparatively little is known about the effect of stress upon the transcortin con-

centration of the blood, except that in the presence of greatly raised corticoid levels, a large portion of the protein is bound to the steroids.

One of the most important roles of thyroxine during stress is its ability to stimulate transcortin binding in the rat, whereas corticosterone and to a lesser extent other steroid hormones exert an inhibitory effect on transcortin-binding in the regulation of pituitary-adrenocortical interactions.

Transcortin

Review on the binding of various steroids by plasma and tissue proteins, with a special section on the corticoid-binding globulin of the serum (69 refs.).

Slaunwhite, W. R. Jr., Sandberg, A. A.: "Transcortin: a corticosteroid-binding protein of plasma." *J. Clin. Invest.* **38**: 384-391 (1959). C64,399/59

Characterization of protein in human plasma having a high affinity for cortisol. The authors "propose to call this protein transcortin." Competition experiments indicate that cortisol and corticosterone are bound at different sites. Estrogens, androgens and progesterone are only weakly, or not at all, bound to transcortin. Probably, corticoids bound to transcortin are biologically inactive. Only when the cortisol concentration of the blood exceeds transcortin capacity do marked physiologic effects appear (for example, during stress or after ACTH administration). The chemical characteristics of this hormone are briefly described.

Daughaday, W. H., Mariz, I. K.: "The binding of steroid hormones by plasma proteins." In: Pincus, G. and Vollmer, E. P., *Biological Activities of Steroids in Relation*

to Cancer, pp. 61-73. New York and London: Academic Press, 1960. J12,259/60

Various proteins in human plasma bind estrogens, progesterone, testosterone and corticoids. An α -globulin is particularly effective in binding cortisol, but its concentration is so small that it can bind only 20 μ g. per 100 ml. of plasma. "The binding site(s) of the corticosteroid-binding globulin seem to be relatively specific for the corticosteroid hormones." In pregnancy and after administration of estrogens, there appears an additional protein that resembles the corticoid-binding globulin in its electrophoretic behavior, but its binding properties are less influenced by temperature.

Steenburg, R. W., Smith, L. L., Moore, F. D.: "Conjugated 17 hydroxycorticosteroids in plasma: measurement and significance in relation to surgical trauma." *J. Clin. Endocrinol. Metab.* **21**: 39-52 (1961).

C98,414/61

In man, gastrectomy caused a rapid rise in the level of serum free 17-OHCS and a slower elevation of conjugated 17-OHCS, but these differences were not statistically significant. In adrenalectomized dogs receiving constant intravenous infusions of cortisol, laparotomy elicited a rise in plasma free 17-OHCS, but this manifestation of a delay in steroid metabolism was not correlated with a fall in the plasma level of conjugated 17-OHCS, which remained the same or actually increased." It is concluded that the serum concentration of glucuronide conjugates is determined by multiple factors, only one of which is the rate of their production. As such, their concentration in serum does not reflect the changes in the rate of steroid metabolism that often occur following surgical operations."

Slaunwhite, W. R. Jr., Lockie, G. N., Back, N., Sandberg, A. A.: "Inactivity in vivo of transcortin-bound cortisol." *Science* **135**: 1062-1063 (1962). D20,991/62

As indicated by liver glycogen maintenance in adrenalectomized mice, transcortin-bound cortisol is biologically inactive.

"In an in vitro system, employing either human or rat liver microsomes, transcortin competes efficiently for hydrocortisone with the enzyme systems responsible for the reduction of the steroid, resulting in lesser metabolism of hydrocortisone in the presence of transcortin" (10 refs.).

Murray, D.: "Cortisol binding to plasma proteins in man in health, stress and at death." *J. Endocrinol.* **39**: 571-591 (1967).

J22,565/67

Labrie, F., Raynaud, J. P., Pelletier, G., Ducommun, P., Fortier, C.: "Corticosterone-binding by transcortin and pituitary-thyroid-adrenocortical interactions in the rat." In: Jasmin, G., *Endocrine Aspects of Disease Processes*, pp. 20-26. St. Louis: Warren H Green, 1968. E7,614/68

In rats, graded doses of thyroxine cause progressive increases in adrenal weight, presumably as a consequence of enhanced ACTH secretion. At the same time, there is a step-wise elevation of total plasma corticosterone without significant alteration in the absolute level of the unbound fraction. Presumably, only free corticosterone is responsible for the feedback mechanism, while the binding capacity of transcortin is responsible for adjustments in the rate of corticosterone secretion to changes in thyroid activity. Furthermore, "thyroxine alone has a direct enhancing effect on the binding capacity of transcortin" and "the stimulating effect of estrogen and progesterone is exerted through the pituitary-thyroid axis."

Stark, E., Acs, Z., Szalay, K. S.: "Further studies on the hypophyseal-adrenocortical response to various stressing procedures in ACTH-treated rats." *Acta Physiol. Acad. Sci. Hung.* **36**: 55-61 (1969). G74,546/69

Following five consecutive daily injections of ACTH, the plasma transcortin level decreases significantly in the rat.

Fortier, C., Labrie, F., Pelletier, G., Raynaud, J. P., Ducommun, P., Delgado, A.,

Labrie, R., Ho-Kim, M.-A.: "Recent studies on the feedback control of ACTH secretion, with particular reference to the role of transcortin in pituitary thyroid-adrenocortical interactions." In: Wolstenholme, G. E. W. and Knight, J., *Ciba Foundation Symposium on Control Processes in Multicellular Organisms*, pp. 178-209. London: J & A Churchill, 1970. G74,630/70

In rats, thyroxine increases transcortin binding sites and thereby influences the feedback control of ACTH secretion, since the unbound, not the total, corticosterone concentration is the variable factor during this homeostatic reaction. On the other hand, in man, cortisol enhances the effect of thyroxine on transcortin binding, and this multiplies the action of the thyroid hormone upon the corticoid feedback.

Fortier, C., Delgado, A., Ducommun, P., Ducommun, S., Dupont, A., Jobin, M., Kraicer, J., MacIntosh-Hardt, B., Marceau, H., Mialhe, P., Mialhe-Voloss, C., Rerup, C., Rees, G. P. van: "Functional interrelationships between the adenohypophysis, thyroid, adrenal cortex and gonads." *Can. Med. Assoc. J.* **103**: 864-874 (1970). H30,500/70

Excellent review, based mostly on the authors' investigations. They reached the following conclusions: "Thyroxine alone having a direct stimulating effect on transcortin binding, appears as the final common pathway in the mediation of the stimulating effects induced by estradiol and progesterone in the intact animal. Corticosterone and, to a lesser extent, estradiol, progesterone and testosterone exert inhibitory effects on transcortin binding in the hypophysectomized animal. Transcortin binding thus seems to play a key role, in the rat, as target and agent of hormonal interactions." These complex interrelations are summarized in Figure 22 (p. 1114).

Marple, D. N., Cassens, R. G., Topel, D. G., Christian, L. L.: "Porcine corticosteroid-binding globulin: binding properties and levels in stress-susceptible swine." *J. Anim. Sci.* **38**: 1224-1228 (1974).

J21,599/74

"Swine from a herd bred to be stress-susceptible had significantly higher mean plasma cortisol and corticosteroid-binding globulin (CBG) levels with a significantly lower mean cortisol-CBG association constant than normal swine."

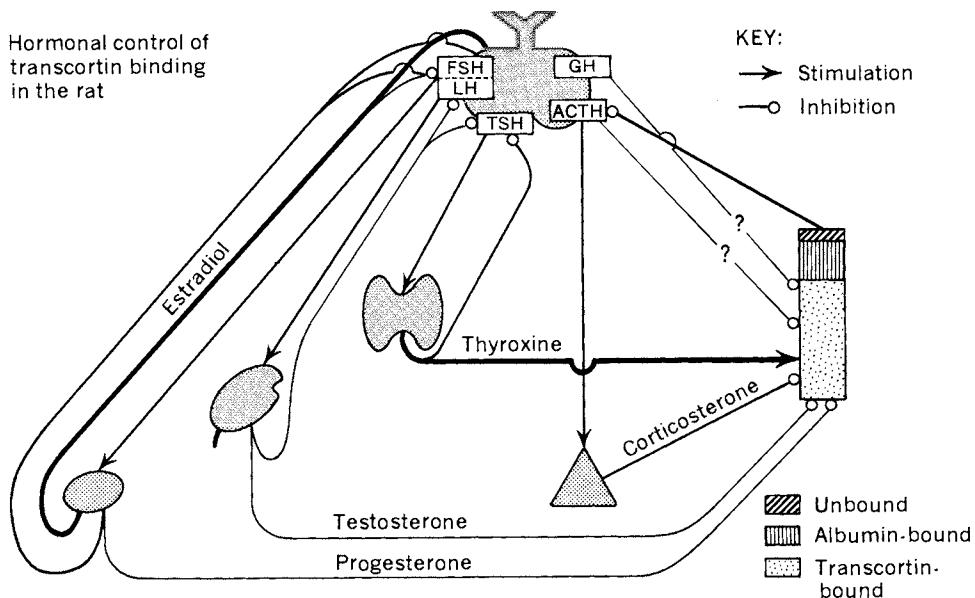

Figure 22. Interactions between the adenohypophysis, thyroid, adrenal cortex and gonads, showing the role of the thyroid and of corticosteroid-binding by transcortin in the adjustment of pituitary-adrenocortical activity in the rat. (Reproduced from *Can. Med. Assoc. J.* 103 (1970) by permission.)

THE SHIFT IN ADENOHYPOPHYSAL ACTIVITY

Even the earliest experiments on the G.A.S. showed clearly that during stress, when stimulation of adrenocortical development and function is of vital importance, other functions including somatic growth, sexual development, lactation and thyroid activity, are almost invariably diminished. From this it was concluded that during emergencies the increased production of life-maintaining ACTH is accomplished at the expense of other less urgently needed hypophyseal principles. It seemed reasonable to assume that, when the anterior pituitary is maximally engaged in the production of one type of hormone (ACTH), its ability to produce other principles (STH, LTH, LH, FSH, TTH) must be diminished. However, this interpretation was based exclusively on structural and functional changes during stress. Subsequent hormone determinations showed that in many instances a stress-induced rise in ACTH production is in fact associated with a diminution in the elaboration of other adenohypophyseal principles. Yet this is not always the case; sometimes it is not the production, but only the effect of other pituitary hormones that is reduced, presumably as a result of inhibitory conditioning factors.

Soon after the formulation of the hypophyseal shift theory, it was shown that, in rats exposed to various stressors, there is a reduction in the uptake of ^{131}I by the thyroid, evidenced by radioautographic observations. It was concluded that stress decreases TTH production. On the other hand, as we have mentioned elsewhere, certain strains of wild rabbits develop acute hyperthyroidism under the influence of stress produced by fear. In rats, exposure to cold increases not only ACTH but also gonado-

tropic hormone production, as indicated by precocious puberty, and it is well known that exposure to low temperatures augments thyroid activity to maintain homeostasis through an increase in the BMR.

Extensive subsequent investigations showed that the most diverse stressors decrease radioiodine uptake by the rat thyroid simultaneously with an increase in ACTH secretion; but this is not an infallible sign of thyroid activity, since stress and cortisone increase the renal clearance of iodine. On the other hand, in adrenalectomized animals, this response remained demonstrable and hence it was assumed that "inhibition of thyroid activity seen after exposure to stress is due to a decreased secretion of pituitary thyrotrophic hormone."

Hormone determination in the adenohypophysis of the rat revealed that after certain interventions the storage of ACTH may be diminished concurrently with an increased gonadotropin concentration, but that the two phenomena are not strictly interdependent. Hence, the "shift in pituitary hormone formation" can be modified by numerous circumstances, and is not an unavoidable consequence of increased secretion of one pituitary hormone.

During acute stress, the rat may show a sudden simultaneous release of both ACTH and gonadotropins, which appears to be incompatible with the theory of a "shift in anterior pituitary hormone secretion."

Other experiments suggest that the stress-induced "pituitary shift . . . might be a hypothalamic rather than a pituitary phenomenon." Thus animals given an intracarotid injection of hypothalamic extract—containing ACTH-, FSH-, LH- and TTH-releasing factors—can secrete all these hormones simultaneously. Other data also support the view that the shift takes place in the hypothalamus and results from the inability of the latter to produce all the releasing factors at the same time.

The situation is further complicated by the fact that thyroxine raises the corticoid-binding capacity of transcortin.

In rats, acute stress increases the ACTH and decreases the TTH content of the plasma, which would support the "hypophyseal shift" theory, but when ACTH secretion is blocked by dexamethasone or other agents, the decrease in TTH secretion persists. These observations have been considered to be incompatible with the shift theory but this is not necessarily so. The metabolic processes preparing an adenohypophyseal cell for ACTH production may interfere with the secretion of TTH, even if an actual discharge of ACTH is blocked by the feedback mechanism. Furthermore, the concurrent rise in TTH and ACTH secretion during cold is a poor example; exposure to low temperatures makes a very strong specific demand upon homeostatic mechanisms that maintain the body temperature, and under these conditions, the inhibitory effect of the shift phenomenon may be overcome. During continuous nervous stimulation, there may be a concurrent increase in the functional activity of the thyroid and the pituitary in the rat, but the investigators were careful to point out that occasional exceptions of this kind do not necessarily indicate that the shift does not occur under the influence of other stressors.

In rats, a variety of stressors caused a rise in plasma corticosterone with a corresponding fall in STH. These findings were considered to be consonant with the pituitary shift theory.

In summary, it may be said that the original observations made in the 1930s—that, during chronic exposure to stress, increased adrenal activity is associated with a diminution of most if not all other phenomena governed by the anterior pituitary—have received ample confirmation. A shift in adenohypophyseal activity is undoubtedly

characteristic of severe chronic stress. On the other hand, it is equally clear that the difficulty of producing several hormones simultaneously can be overcome if the stimulus is sufficiently severe. For example, during exposure to cold or at normal temperatures in certain species of wild rabbits, the specific impulse to produce excess TTH is so strong that it occurs despite a simultaneous rise in ACTH secretion. Furthermore, there is some doubt whether the shift really occurs at the adenohypophyseal level or in the hypothalamic centers regulating the production of the various releasing factors. Finally, we now have more evidence than we had forty years ago, when the shift theory was first formulated, that manifestations of adenohypophyseal activity do not depend merely upon the amount of anterior pituitary hormone secreted but, to an equal and often greater degree, upon conditioning factors modifying the receptivity of target organs to anterior pituitary hormones.

Much further work will be necessary to elucidate all the implications of the shift theory, but from a practical point of view the original concept is as valid today as it was when first enunciated; during stress, the safeguarding of an increased adrenocortical activity, indispensable for maintenance of life, must take preference over many other phenomena controlled by the adenohypophysis, such as the sexual cycle, fertility, lactation, somatic growth and thyroid activity. Whatever the underlying mechanism—and it is not necessarily always the same—examination of patients or experimental animals under chronic stress shows that the high degree of adrenocortical activity is maintained during severe and chronic emergencies, often at the expense of other less urgently required manifestations of life.

The Shift in Adenohypophyseal Activity

Dohan, F. C.: "Effect of low atmospheric pressure on the adrenals, thymus and testes of rats." *Proc. Soc. Exp. Biol. Med.* **49**: 404-408 (1942). A37,744/42

"Rats exposed to low atmospheric pressure for more than 2 days exhibited a significant increase in adrenal weight and a significant decrease in the weight of the thymus and testes. This pattern is similar to that found following other forms of stress." These observations are in consonance with the "pituitary shift" theory.

Selye, H.: *Textbook of Endocrinology*, p. 914. Montreal: Acta, 1947. 94,572/47

Experiments on rats exposed to various stressors indicate that growth, sexual development, lactation and thyroid activity are almost invariably diminished, whereas adrenal cortical stimulation is uniformly augmented. It is concluded that "in emergencies, an increased production of the life-maintaining corticotrophic hormone is accomplished at the expense of other, less urgently needed, hypophysial principles."

Bogoroch, R., Timiras, P.: "The response of the thyroid gland of the rat to severe stress." *Endocrinology* **49**: 548-556 (1951).

B59,195/51

In rats, various stressors (formalin, spinal cord transection, muscular exercise) depressed the uptake of ^{131}I in the thyroid, as indicated by radioautographic studies. "It was suggested that stress caused a decrease or suppression of thyrotrophic stimulation."

Mandl, A. M., Zuckerman, S.: "Factors influencing the onset of puberty in albino rats." *J. Endocrinol.* **8**: 357-364 (1952).

B75,210/52

In rats, exposure to cold accelerates the vaginal opening (a sign of puberty), whereas rough handling and a high-protein diet have no such effect. Possibly, certain types of "nonspecific 'stress'" may bring about a raised output of gonadotrophin as well as of ACTH, and thus secondarily stimulate ovarian activity."

Conner, M. H., Shaffner, C. S.: "Effect of altered thyroidal and gonadal activity on size of endocrine glands and resistance to stress in the chick." *Endocrinology* **55**: 45-53 (1954).

B95,026/54

Trolle, D.: "Experimental and clinical investigations on the pregnanediol excretion in human urine. IV. Depression of the corpus luteum function following hormone administration and under stress." *Acta Endocrinol.* (Kh.) **20**: 57-62 (1955). C9,372/55

Jänkälä, E. O., Näätänen, E. K.: "Effect of intense mental strain on the morphological picture of the testes." *Ann. Med. Exp. Fenn.* **33**: 231-238 (1955). C9,646/55

Harris, G. W.: "The reciprocal relationship between the thyroid and adrenocortical responses to stress." In: Wolstenholme, G. E. W. and Cameron, M. P., *Ciba Foundation Colloquia on Endocrinology*, Vol. 8, pp. 531-550. London: J & A Churchill, 1955. C3,662/55

Review of the literature indicating that a variety of stressors (typhoid vaccine, trauma, fasting, cold, heat, formalin, spinal cord transection, anoxia, starvation, tourniquet shock) decrease the uptake of radioiodine by the thyroid of the rat although they simultaneously increase ACTH secretion. However, radioiodine uptake by the thyroid during stress does not give a specific indication of thyroid activity, since stress and cortisone enhance the renal clearance of iodine and may thus lead to an apparent decrease in thyroid uptake, because less radioiodine is available. Animals with their adrenals denervated or removed (while maintained on a constant cortisone regime) show a similar response, and hence it is assumed that "the inhibition of thyroid activity seen after exposure to stress is due to a decreased secretion of pituitary thyrotrophic hormone."

Nowell, N. W., Jones, I. C.: "Some aspects of the storage and secretion of corticotrophin and gonadotrophins." *Acta Endocrinol.* **26**: 273-285 (1957). C43,163/57

Comparative estimates of the ACTH and gonadotropin content of the adenohypophysis in male and female intact, castrated and adrenal-enucleated rats and those exposed to "cold stress" led the authors to the conclusion that, "under certain conditions, firstly, the storage of corticotrophin may be diminished when that of gonadotrophins is increased but this is not necessarily associated with a diminution of corticotrophin secretion; secondly, when the production of corticotrophin is increased, the storage of gonadotrophins may be lessened in some cases and there may be some diminution in gonadotro-

phin secretion; thirdly, the rate of secretion of corticotrophin is not primarily related to the rate of secretion of gonadotrophins but may be secondarily so, through the influence of other factors, including the sex steroids; fourthly, cold stress is accompanied by the liberation of stored corticotrophin which may be associated with some gonadotrophin release in females but not in males." Hence the "shift in pituitary hormone formation" can be modified by numerous circumstances and is not an unavoidable consequence of increased secretion of one adenohypophyseal hormone.

Arvay, A., Balázsy, L.: "Changes in the gonadotropic function of the adenohypophysis in response to nervous stress." *Acta Physiol. Acad. Sci. Hung.* **14**: 317-325 (1958). C69,256/58

On the basis of cytochemical changes in the rat pituitary, it is assumed that stressors increase gonadotropin production with simultaneous enhancement of ACTH release. This would be incompatible with the theory of a "shift in anterior pituitary hormone secretion" during stress.

Igarashi, M., Tohma, K., Ozawa, M., Hosaka, H., Matsumoto, S.: "Pathogenesis of psychogenic amenorrhea and anovulation." *Int. J. Fertil.* **10**: 311-319 (1965).

F54,882/65

In women with amenorrhea or anovulation following psychogenic stress, hypersecretion of ACTH coincided with low elimination of FSH, 17-KS and 17-OHCS. "Selye proposed a hypothesis called the 'shift theory' that stress increases ACTH secretion from the pituitary at the sacrifice of gonadotropin secretion. His hypothesis was not based on assay of gonadotropin, but only on finding of ovarian atrophy in rats under stress. Therefore our results seem to give the first actual supportive evidence to Selye's hypothesis."

Ramirez, V. D., Moore, D., McCann, S. M.: "Independence of luteinizing hormone and adrenocorticotrophin secretion in the rat." *Proc. Soc. Exp. Biol. Med.* **118**: 169-173 (1965). F30,129/65

In spayed rats, adrenalectomy causes only a "borderline rise" in plasma LH, whereas large doses of cortisol fail to affect it, although they suppress the ACTH concentration in the pituitary and elevate the LH level. Apparently, "alteration in target gland steroids produces specific effects on LH in

the case of ovarian steroids, and ACTH in the case of cortical steroids."

Martini, L., Fraschini, F., Motta, M.: "New data on the nervous control of the pituitary gland." 2nd Int. Congr. on Hormonal Steroids, Milan, 1966. *Int. Congr. Ser. No. 111*, p. 94. Amsterdam and New York: Excerpta Medica, 1966. J13,139/66

Brief abstract describing animal experiments which suggest that the stress-induced "pituitary shift . . . might be a hypothalamic rather than a pituitary phenomenon." Thus, animals [species not stated] given an intracarotid injection of a hypothalamic extract containing the releasing factors for ACTH, FSH, LH, STH and TTH, can secrete all these hormones simultaneously. "Additional support for the hypothesis that the 'shift' takes place in the hypothalamus comes from the data indicating that in situations in which the pituitary shifts from one hormone to another an analogous 'shift' occurs in the synthesis and/or release of the corresponding hypothalamic releasing factors."

Labrie, F., Raynaud, J. P., Pelletier, G., Ducommun, P., Fortier, C.: "Corticosterone-binding by transcartin and pituitary-thyroid-adrenocortical interactions in the rat." In: Jasmin, G., *Endocrine Aspects of Disease Processes*, pp. 20-23, St. Louis: Warren H Green, 1968. E7,614/68

In rats, graded doses of thyroxine cause progressive increases in adrenal weight, presumably as a consequence of enhanced ACTH secretion. At the same time, there is a step-wise elevation of total plasma corticosterone without significant alteration in the absolute level of the unbound fraction. Presumably, only free corticosterone is responsible for the feedback mechanism, while the binding capacity of transcartin is responsible for adjustments in the rate of corticosterone secretion to changes in thyroid activity. Furthermore, "thyroxine alone has a direct enhancing effect on the binding capacity of transcartin" and "the stimulating effect of estrogen and progesterone is exerted through the pituitary-thyroid axis."

Ducommun, P.: "Corticosterone-binding by transcartin and pituitary-thyroid-adrenocortical interactions in the rat: discussion." In: Jasmin, G., *Endocrine Aspects of Disease Processes*, pp. 23-26. St. Louis: Warren H Green, 1968. E10,627/68

In rats, acute stress [kind not stated] suddenly increases the ACTH and diminishes the TTH content of the plasma, a finding

that would agree with the "hypophyseal shift" theory. However, when ACTH release is blocked by dexamethasone-Nembutal, TTH secretion continues to fall. Conversely, exposure to cold elicits a simultaneous increase in plasma ACTH and TTH.

Arvay, Á., Balogh, A., Ladányi, P., Takács, I., Benkő, K.: "Effect of intensive nervous stimulation on the fine structure of the adenohypophysis and its target organs." *Acta Endocrinol. (Kbh.)* 68: 749-758 (1971).

H50,211/71

In rats subjected to prolonged nervous stimulation, EM studies of the pituitary-adrenal cortex, thyroid and ovaries suggested increased functional activity. This finding appears to be in contradiction to the "pituitary shift" theory, but such multiple pituitary hormone stimulation may not occur under the influence of other stressors.

Ajika, K., Kalra, S. P., Fawcett, C. P., Krulich, L., McCann, S. M.: "The effect of stress and Nembutal on plasma levels of gonadotropins and prolactin in ovariectomized rats." *Endocrinology* 90: 707-715 (1972).

H52,545/72

"The stress of etherization and bleeding produced an elevation within 2 min in the plasma levels of prolactin, LH, and FSH in ovariectomized rats. . . . Nembutal blocked the stress-induced elevations of plasma prolactin and LH but did not affect the levels of FSH. The effect of Nembutal is thought to be on the CNS since the Nembutalized rats responded to hypothalamic extract or ovine LRF with dramatic elevations in plasma LH." [Evidently, under these acute stress conditions, a shift in adenohypophyseal hormone production does not interfere with a simultaneous secretion of several anterior pituitary hormones (H.S.).]

Kokka, N., Garcia, J. F., George, R., Elliott, H. W.: "Growth hormone and ACTH secretion: evidence for an inverse relationship in rats." *Endocrinology* 90: 735-743 (1972).

H52,549/72

In rats, noise, vibration, ether, cold, insulin, pentylenetetrazol, amphetamine and 2-D-deoxyglucose caused a rise in plasma corticosterone with a corresponding fall in STH. Gentling or administration of pentobarbital lowered corticosterone and increased STH in plasma. The results are interpreted as indicating an inverse relationship between ACTH and STH secretion; this finding agrees with the "pituitary shift" theory.

Leppäläluoto, J., Ranta, T., Lybeck, H., Varis, R.: "Effect of TRH, and short-term exposure to experimental stress or cold on the serum immunoassayable TSH concentration in the rat." *Acta Physiol. Scand.* **90**: 640-644 (1974). J13,381/74

Various acute stressors temporarily raise plasma TTH levels, but this is followed by a lasting and pronounced decrease. Only cold causes a specific increase in plasma TTH activity. "The inhibition of TSH [TTH] secretion in response to stress refutes the hypothesis that stressful stimuli activate the thyroid gland."

Rosen, E. F., Petty, L. C.: "Food deprivation effects on some estrogen-sensitive responses in female rats." *Physiol. Behav.* **12**: 767-770 (1974). J12,899/74

Observations in man during famines, as well as experiments on the folliculoid sensitivity of rats and other animals during stress, suggest that "food deprivation may interfere with sexual activity by altering the female's behavior more than the male's. Thus, any control over reproduction which may occur in a famine area may be due to changes in the female's behavior, which provide fewer or lower intensity stimuli to the male....

This is part of the response to stress discussed by Selye."

Inoue, S., Nagasaki, H., Iriki, M.: "Total sleep deprivation and weight increases of the reproductive organs in male rats." *Endocrinol. Jap.* **21**: 283-286 (1974). H92,991/74

In rats, long-term sleep deprivation in a cage, where they were continuously forced to move in order to avoid electric shocks, caused hypertrophy of the adrenals, testes, ventral prostates and seminal vesicles. "It is supposed that either the sleep deprivation *per se* or stressful conditions accompanied with the treatment caused a hypersecretion of hypophyseal and testicular hormones." [It is unusual for chronic stress to produce hypertrophy of the sex organs, and these observations appear to be incompatible with the pituitary-shift theory (H.S.).]

Euker, J. S., Meites, J., Riegler, G. D.: "Effects of acute stress on serum LH and prolactin in intact, castrate and dexamethasone-treated male rats." *Endocrinology* **96**: 85-92 (1975). H98,033/75

In rats, ACTH, LTH and LH concentrations in the blood may be increased by some stressors. Hence, a shift in anterior pituitary production is by no means the rule.

SYNTOXIC AND CATATOXIC HORMONES

The participation of syntoxic and catatotoxic hormones in stress reactions was the topic of one of my earlier monographs on the mechanism of the G.A.S. (*Hormones and Resistance*, 1971). There I tried to distinguish between two types of adaptive steroids that control essentially different processes:

1. The syntoxic steroids (e.g., cortisol, triamcinolone, aldosterone, desoxycorticosterone) permit adjustment to topical or systemic injury without directly attacking the aggressor. They create conditions for coexistence with toxic agents, either through passive indulgence to them (e.g., antiphlogistics), or by actively stimulating the formation of a granulomatous barricade, which tends to isolate the irritant from the surrounding tissue (e.g., prophlogistics). Through similar mechanisms, the syntoxic steroids also promote repair (e.g., cicatrization).

The systemic action of the syntoxic steroids is mainly of the "life-maintaining corticoid" type; it is highly efficient in restoring the nonspecific resistance of adrenal-deficient organisms to normal, but then, it reaches a plateau above which tolerance is not easily raised. Only in a few instances (e.g., damage due to endotoxins, inflammatory irritants, immune reactions, lathyrogenic compounds) can syntoxic steroids increase tolerance far above normal because here, the "disease" is primarily due to active morbid reactions of the tissues, not to passive, direct

tissue damage by the exogenous aggressor. Thus, endotoxin shock is thought to be caused mainly by the liberation of enzymes normally sequestered in lysosomes, whereas inflammation, various pathogenic immune reactions (allergies, anaphylaxis, homograft rejection) and osteolathyrysm represent excessive responses of the body to different types of irritation. In all these cases, homeostasis is achieved by adjusting the body's reaction to the damaging agent, not by destroying the latter.

2. **The catatoxic steroids** (e.g., ethylestrenol, spironolactone, certain cyano-steroids) act primarily by stimulating aggressive reactions which destroy toxic substances (e.g., by accelerating their metabolic degradation). They do not merely restore a deficient resistance to normal (as do the glucocorticoids after adrenalectomy), but they are capable of raising it far above the norm. Sometimes this reaction defeats its purpose, because the products of metabolic degradation are more toxic than the original drug which was to be inactivated. Yet, the response is still catatoxic since it attacks the aggressor. For similar reasons, we speak of allergy and anaphylaxis as "immune reactions," although they actually produce damage.

There are many overlaps between syntoxic and catatoxic steroid actions, for example, the stimulation of inflammation may lead to topical degradation of the irritant by enzyme activation in the inflammatory focus; furthermore, certain primarily syntoxic glucocorticoids (e.g., dexamethasone) may also enhance the hepatic detoxication of barbiturates. Yet, the distinction between the two categories is justified because, usually, individual hormones act predominantly by eliciting one or the other reaction form. Furthermore, available evidence suggests that the two types of defense are mediated through essentially distinct mechanisms.

There can be no doubt that during stress an increased amount of syntoxic steroids (for example, cortisol, corticosterone) is produced in response to the need to maintain homeostasis. The same is true of catecholamines, since more than the resting level of these hormones is required to maintain health when unusual demands for adaptation are made. However, this has never been proven for catatoxic steroids. The latter are undoubtedly manufactured by the body since natural testoids, corticoids and luteoids have been proven to exert definite catatoxic effects. Thus, for example, even at a normal blood level, testosterone participates in the detoxication of barbiturates through its catatoxic activity, since resistance to these drugs decreases below normal after castration and can be restored by exogenous testoids. Yet the fundamental question whether increased amounts of these or other catatoxic steroids are actually produced for the maintenance of homeostasis in reply to needs created by stress has not yet been definitively answered.

Syntoxic and Catatoxic Hormones

(See also our earlier stress monographs, p. xiii)

Selye, H.: *Hormones and Resistance*, 2 vols., p. 1140. New York, Heidelberg and Berlin: Springer-Verlag, 1971. G79,100/71

Encyclopedic treatise on the role of various hormones in resistance to specific and stres-

sor agents. First detailed description of the difference between syntoxic and catatoxic hormones and the results of extensive screenings of steroids for these actions. Among all compounds tested, pregnenolone- 16α -carbonitrile (PCN) proved to be the most active catatoxic substance.

Wassermann, D., Wassermann, M., Cucos,

S., Djavaherian, M.: "Function of adrenal gland-zona fasciculata in rats receiving polychlorinated biphenyls." *Environ. Res.* **6**: 334-338 (1973). J6,552/73

In rats given toxic polychlorinated biphenyls, the plasma corticosterone levels rose sharply, and characteristic structural changes developed in the fasciculata of the adrenals. "The results are interpreted as evidence of the need for a higher level of glucosteroids in defense against the stressor character of PCBs-1221 and perhaps also of the need for cataotoxic activity of glucosteroids."

Kourounakis, P., Szabo, S., Selye, H.: "Effect of fluorosteroids upon drug response and metabolism." *Biochem. Pharmacol.* In press. J4,268/75

In rats, in vivo observations on the paralysis produced by zoxazolamine and parallel studies on the blood clearance of this toxicant showed that "PCN and spironolactone protect via increased drug metabolism, triamcinolone and ACTH via decreased organ sensitivity, and the remaining fluorosteroids via both prophylactic mechanisms."

OTHER HORMONES AND HORMONE-LIKE SUBSTANCES

The participation of other hormones in stress reactions has already been discussed in connection with the chemical characteristics of the G.A.S., where data on changes in the blood and tissue concentrations of various hormones and related substances have been listed. The observations on the stressor effect of various hormones and hormone-like substances other than those mentioned in the preceding pages, as well as changes in their metabolism during stress, have shown that insulin, glucagon, thyroid hormones, and possibly even pineal and thymus hormones, participate in the mechanism of stress reactions. The same is true of such hormone-like substances as 5-HT, histamine, acetylcholine, prostaglandins and GABA, which appear to fulfill very important roles, not only as systemic mediators, but also as local transmitters of impulses, especially in the CNS. 5-HT deserves special attention.

5-HT. Studies with radioactive NEP and 5-HT in rats reveal that various stressors deplete brain NEP, but at least initially, increase the 5-HT content, especially of the brain stem-mesencephalon and spinal cord. It has also been demonstrated that a variety of stressors increase the concentration of 5-HIAA and tryptophan in the rat brain and that the rise in 5-HT is most persistent and pronounced if 5-HT degradation is blocked by MAO inhibitors. Cortisol increases hepatic tryptophan pyrolase activity, 5-HT and 5-HIAA, at least in rats of certain age groups.

Presumably, the rise in brain 5-HT that is characteristic of stress is largely dependent upon enzymatic processes affecting its degradation and resynthesis. However, in all these respects, the literature is far from unanimous, perhaps largely because certain authors have neglected to consider the time curve of 5-HT during stress, which by some is attributed to the existence of a 5-HT negative feedback system. Furthermore, there are obvious differences between the responses of various brain areas in this respect. In any event, it appears to be well established that brain NEP and 5-HT concentrations do not always vary in a parallel fashion during stress, because when NEP is depleted, 5-HT is either raised or at least unchanged. Several investigators have come to the conclusion that serotonergic neurons may play an important part in ACTH release.

5-HT concentration is highest in the raphé nuclei (containing the highest level of serotonergic cell bodies), particularly the amygdala and hippocampus, in which it

shows definite circadian variations. Destruction of these nuclei abolishes the circadian plasma corticosterone rhythm in the rat.

According to some investigators, acute stress induces a biphasic response in the hypothalamic 5-HT content. It consists of an initial decrease (which precedes the increase in plasma corticosterone and is independent of the pituitary-adrenal system), followed by a second phase, which is characterized by a rise in hypothalamic 5-HT with a subsequent return to normal. It is noteworthy that, despite the enormous literature dealing with 5-HT metabolism during stress and its relation to ACTH discharge, almost every statement made by one author has been contradicted by another. Hence, despite the large number of data on record, a critical reexamination of this entire field, both with regard to the existing literature and by well-planned additional experiments, appears to be of the utmost importance. It is for efforts of this kind that we hope that the present encyclopedic survey of the field may have the greatest heuristic value.

Other Hormones and Hormone-like Substances

(See also our earlier stress monographs, p. xiii, and cf. Hormones and Hormone-like Substances under Characteristic Manifestations of Stress, and Various Mechanisms)

Thyroid. Selye, H.: "Studies on adaptation." *Endocrinology* **21**: 169-188 (1937).

B95,026/37

Hypophysectomy lessens the accidental involution of the thymus, and adrenalectomy inhibits it completely, but both these operations greatly diminish resistance to all stressors examined. Thyroidectomy and ovariectomy do not considerably interfere with the thymicolympathic involution and splenic atrophy characteristic of the formalin-induced alarm reaction, nor do they significantly increase mortality.

Conner, M. H., Shaffner, C. S.: "Effect of altered thyroidal and gonadal activity on size of endocrine glands and resistance to stress in the chick." *Endocrinology* **55**: 45-53 (1954).

B95,026/54

Skebelskaia, I. B.: "Thyroid gland reaction to 'stress' after the exclusion of the adrenocorticotrophic function of the hypophysis." *Probl. Endokrinol. Gormonoter.* **5** No. 6: 3-6 (1959) (Russian). D98,428/59

Notti, P., Santoro, G.: "Tiroide e 'stress'" (The thyroid and stress). *Riv. Patol. Clin.* **14**: 755-762 (1959). C90,723/59

J24,542/60

"In epiphysectomized rats (unlike in those which have been subjected to a sham operation only), the formol stress is not followed by eosinopenia." It is suggested that the pineal is indispensable for the normal development of the alarm reaction.

Miline, R., Devecerski, V., Krstic, R.: "Les modifications épiphysaires dans le stress et en particulier dans les névroses expérimentales d'effroi" (Epiphyseal changes in stress and especially in experimental neuroses due to fright). *Probl. Actuels Endocrinol. Nutr. Ser. No. 10*: 229-256 (1967). F81,524/67

Kinson, G., Wahid, A. K., Singer, B.: "Effect of chronic pinealectomy on adrenocortical hormone secretion rates in normal and hypertensive rats." *Gen. Comp. Endocrinol.* **8**: 445-454 (1967). F80,842/67

Experiments on rats indicate that one month after pinealectomy, aldosterone and corticosterone secretion is significantly increased. "These chronic ablation studies suggest that the pineal gland normally exerts an inhibitory effect on the adrenal cortex which is not confined to aldosterone."

Miline, R., Krstić, R., Devečerski, V.: "Sur le comportement de la glande pinéale dans des conditions de stress" (On the behavior of the pineal gland under conditions of stress). *Acta Anat. (Basel)* **71**: 352-402 (1968). G68,038/68

Description of changes in the pineal gland of restrained rats. "The results obtained indicate the progressive nature of the reaction of the pineal gland and the stress of constraint. The authors believe that the pineal gland plays a sensoneuroendocrine role."

Miline, R.: "Role of the pineal in cold

adaptation: general discussion." In: Wolstenholme, G. E. W. and Knight, J., *The Pineal Gland*, pp. 372-373. Edinburgh and London: Churchill Livingstone, 1971.

J14,884/71

Dyer, R. S., Weldon, D. A., Mento, A. J.: "Pinealectomy and two-way avoidance in the guinea pig (*Cavia porcellus*)."*Physiol. Behav.* **12**: 671-673 (1974). J13,148/74

In guinea pigs, pinealectomy had no effect on two-way avoidance learning. "This suggests that blindness-induced facilitation of two-way avoidance in guinea pigs is not a result of the hormonal changes in the pineal known to accompany variations in visual input." These findings are considered interesting in connection with stress reactions because ACTH secretion is thought to be partly controlled by the pineal gland.

Reiter, R. J.: "Pineal regulation of hypothalamic-pituitary axis: gonadotrophins." In: Greep, R. O. and Astwood, E. B., *Handbook of Physiology. Section 7. Endocrinology*, Vol. IV, Part 2, pp. 519-550. Washington, D.C.: American Physiological Society, 1974.

Chazov, E. I., Golikov, P. P., Bobkova, A. S., Fominikh, E. S.: "The effect of epiphysis on stress." *Patol. Fiziol. Éksp. Ter.* No. 5: 12-17 (1974) (Russian). J25,498/74

"The rate of corticosterone decreased in the epiphysectomized rats during the neuro-reflex phase of systemic stress; as to the metabolic phase, there occurred an increase in the rate of aldosterone, corticosterone, 18-OH-DOC secretion, and the adrenal glands gained weight. Consequently, epiphysis takes part in the development of the general adaptation syndrome."

Thymicolumphatic Apparatus and Bursa. Nigeon-Dureuil, M., Rabinowicz, M., Rahandraha, T., Ratsimamanga, A. R.: "Signification des variations pondérales et biochimiques transitoires de l'hypophyse, de la surrénaïale et du thymus, au cours d'un stimulus continu de moyenne intensité, le froid à 6°" (Significance of the transitory ponderal and biochemical variations of the hypophysis, adrenal, and thymus during exposure to a continuous stimulus of moderate intensity, cold at 6°). *C.R. Soc. Biol. (Paris)* **146**: 370-377 (1952). B75,131/52

In rats exposed to moderate cold, the various manifestations of the G.A.S. show periodic fluctuations, probably due to successive

discharges and storage of hormones. The thymus allegedly can store corticoids and thereby provide an additional reserve. [The authors promised subsequent papers in which these concepts would be elaborated (H.S.).]

Chisci, R.: "Importanza del timo nella sindrome di adattamento. Nota III—Gli effetti dello stress e della somministrazione di ACTH sull'apparato genitale femminile delle ratte normali e stimizzate" (Importance of the thymus in the adaptation syndrome. Note III—Effects of stress and of adrenocorticotrophic hormone on female genitalia of normal and stimulated rats). *Folia Endocrinol.* (Roma) **8**: 525-543 (1955). C8,681/55

In rats, "typical manifestations of the 'alarm reaction' by the cold stress (such as anestrus ovulations, corticoids-estrogens antagonism, fatty infiltration of the liver etc.) are clearly augmented and prolonged by thymectomy so that the adaptation process becomes delayed."

D14,302/61

Thymectomy increased the resistance of the rat to various stressors.

Sackler, A. M., Weltman, A. S., Jurtschuk, P. Jr.: "Effect of splenectomy on the resistance of rats to histamine stress." *Nature* **190**: 274 (1961). E79,123/61

In the rat, "splenectomy tends to increase tolerance to histamine stress."

Csaba, G., Törö, I., Horváth, C., Acs, T., Mold, K.: "Thymus and stress." *J. Endocrinol.* **23**: 423-431 (1962). D17,079/62

Thymectomy slightly exacerbated the course of formalin arthritis, and allegedly "cortisone, which prevented or arrested the arthritis in intact rats, produced serious aggravation of the condition in thymectomized animals. The action of the thymus is not apparently hormonal but depends on the presence of thymic tissue. It seems that this phenomenon is connected with the participation of the thymus in polysaccharide metabolism."

Miller, J. F. A. P., Dukor, P.: *Die Biologie des Thymus nach dem heutigen Stande der*

Forschung (The present status of thymus biology), p. 98. Basel and New York: S Karger, 1964. E4,014/64

Only cursory reference is made to the thymus involution induced by stress; its possible significance in immunologic responses of adults is difficult to appraise (several hundred refs.).

Huston, T. M., Subhas, T.: "The influence of environmental temperature upon adrenal activity of bursectomized chicks." *Poultry Sci.* **47**: 1760-1763 (1968). J23,073/68

Although earlier experiments showed that severe stress causes involution of the bursa in chicks, moderate cold has no such effect. In bursectomized chicks, adrenal ascorbic acid content diminishes, particularly after exposure to stress.

Freeman, B. M.: "The bursa of Fabricius and adrenal cortical activity in *Gallus domesticus*." *Comp. Biochem. Physiol.* **29**: 639-646 (1969). H12,554/69

The depletion of ascorbic acid from the adrenals of chickens is diminished and general resistance increased following bursectomy.

Malyzhev, V. A., Sutkovoi, D. A.: "The effect of thymectomy in guinea pigs on urinary excretion of 17-oxy corticosteroids under normal conditions and in stress." *Patol. Fiziol. Éksp. Ter.* **14** Nos. 5-6: 31-34 (1970) (Russian). J22,295/70

"As shown in guinea pigs thymectomized at immature age, urinary excretion of 17-oxy corticosteroids was almost halved four months after the operation in comparison with intact animals. A more prolonged than normal activation of adrenal cortex was seen both at the early and at the late periods after thymectomy, when these animals were subjected to the action of unfavourable factors, such as operation or inflammation."

Bhattacharyya, T. K., Ghosh, A.: "Influence of surgical and steroid-induced bursectomy on the behavior of adrenal ascorbic acid during stress in juvenile pigeons." *Gen. Comp. Endocrinol.* **15**: 420-424 (1970). H35,126/70

In juvenile pigeons, bursectomy facilitated the depletion of adrenal ascorbic acid during stress (formalin). Cortisol caused involution of the bursa but left adrenal ascorbic acid levels unaltered after exposure to stress.

Watanabe, I., Cabrera-Peralta, C., Pescinini, I. A., Mello, A.: "Efeito da ablação do timo no crescimento de segmentos encefálicos de

ratios" (Effects of thymus ablation on encephalic segment growth of rats). *Rev. Bras. Pesqui. Med. Biol.* **5**: 237-241 (1972) (Portuguese). H81,499/72

"Since the thymus is the organ in the body most responsive to 'stress' and since encephalic structures have a close relation to 'stress,'" the various brain regions were carefully examined in rats after thymectomy on the fourteenth day of life, and certain structural anomalies were observed. [On the basis of the description, the relationship of the latter to stress is not evident (H.S.).]

Pethes, G., Muray, T., Péczely, P.: "Effect of stress on corticosterone production of bursectomized chicken." *Gen. Comp. Endocrinol.* **22**: 400 (1974). H83,307/74

In bursectomized chickens, adrenal weight, adrenal corticosterone production, and pituitary ACTH content were not altered. The effect of stressors (cold, heat, ether) upon corticosterone production was not prevented by bursectomy.

Toma, V., Giurgea, R.: "Dynamics of nucleic acids and total proteins in the thymus and the bursa of Fabricius of chickens, under the action of cortisol." *Zentralbl. Veterinaermed. [A]* **21**: 506-513 (1974) (Roumanian).

J19,417/74

Treatment of murine thymus cells with a thymus humoral factor increased their capacity to elicit a graft-versus-host reaction in vitro and to resist cortisol.

Marx, J.: "Aging research (II): pacemakers for aging?" *Science* **186**: 1196-1197 (1974). H96,194/74

Review of the literature on aging. An informative discussion of the theory according to which involution of the thymus, and the consequent immunologic incompetence, may be at the basis of the genetically determined "biological clock" responsible for the rate of aging.

Toma, V., Giurgea, R.: "Lowering of the ^{32}P -uptake in the thymus, pancreas and adrenals after Bernardi-Comșa thymic extract administration." *Rev. Roum. Méd.* **12**: 109-112 (1974) (Roumanian). J19,093/74

Svendsen, U. G.: "Thymus dependency of periarteritis nodosa in DOCA and salt

treated mice." *Acta Pathol. Microbiol. Scand. [A]* **82**: 30-34 (1974). J16,185/74

Severe periarteritis nodosa develops in the kidneys, with fewer lesions in the heart and pancreas, in unilaterally nephrectomized, haired NMRI mice treated with DOC plus sodium chloride, but not in littermates with congenital thymus aplasia.

5-HT. (See also our earlier stress monographs, p. xiii, and cf. 5-HT under Hormones and Hormone-like Substances in the section on Characteristic Manifestations of Stress).

Liberson, W. T., Bernsohn, J., Wilson, A., Daly, V.: "Brain serotonin content and behavioral stress." *J. Neuropsychiatry* **5**: 363-365 (1964). D17,697/64

In guinea pigs, prolonged hypnosis training significantly decreased the 5-HT content of the cortex and hippocampus, and to a lesser degree, of the brain stem and cerebellum.

Rosecrans, J. A., Feo, J. J. de: "The interrelationships between chronic restraint stress and reserpine sedation." *Arch. Int. Pharmacodyn. Ther.* **157**: 487-497 (1965).

F54,866/65

In rats, stress by restraint initially increased the 5-HT and decreased the NEP content of the brain. "Reserpinized stress animals were more easily handled at first, but became more excitable and difficult to handle as the experiment progressed." This change appeared to correlate with the continued depletion of brain NEP because the brain 5-HT remained approximately constant. The possible protective effect of reserpine is considered in connection with the G.A.S.

Thierry, A.-M., Javoy, F., Glowinski, J., Kety, S. S.: "Effects of stress on the metabolism of norepinephrine, dopamine and serotonin in the central nervous system of the rat. I. Modifications of norepinephrine turnover." *J. Pharmacol. Exp. Ther.* **163**: 163-171 (1968). H2,261/68

By use of radioactive NEP, 5-HT and dopamine, it was found that stress (electroshock) did not significantly influence the endogenous level of NEP but markedly raised its turnover in NEP-containing neurons of

the brainstem-mesencephalon and spinal cord. "This stress increased the synthesis of 5HT in the brainstem-mesencephalon as seen by the greater increase of endogenous 5HT after monoamine oxidase inhibition but did not affect the disappearance of intracisternally administered H³-5HT. Changes in NE turnover regulation induced by electric foot shocks were studied in various conditions. There was an enhanced turnover of NE in the brainstem-mesencephalon when higher intensities of stimulation were used; this was associated with an increased accumulation of H³-nor-metanephrine; no modification was seen when the frequency of stimulation was increased. NE turnover during an acute stress session was enhanced to a greater degree when rats were previously subjected to many stress sessions. The initial accumulation of H³-NE in the brainstem-mesencephalon was decreased just after an acute stress and increased 24 hr after the last electric shock stress session of a chronic stress treatment."

Thierry, A.-M., Fekete, M., Glowinski, J.: "Effects of stress on the metabolism of noradrenaline, dopamine and serotonin (5-HT) in the central nervous system of the rat. II. Modifications of serotonin metabolism." *Eur. J. Pharmacol.* **4**: 384-389 (1968). H5,942/68

Stress induced by mild electric shock to the feet slightly increased the 5-HT content of the brain stem-mesencephalon. "The formation of ³H-5HT from ³H-tryptophan (TRY) was significantly increased in the brain of stressed animals and the utilization of this labelled amine synthesized endogenously was markedly accelerated during the stress situation."

H4,230/68

"The stress of foot shock in rats induces large decreases in the level of brain norepi-

nephrine but does not greatly alter the concentration of serotonin or dopamine in brain."

Goldberg, M. E., Salama, A. I.: "Amphetamine toxicity and brain monoamines in three models of stress." *Toxicol. Appl. Pharmacol.* **14**: 447-456 (1969). G66,997/69

In the mouse and rat, a significant rise in the level of brain stem 5-HT was caused by trauma or electroshock but not by cold. "This increase was obtained in animals subjected to stress alone, or those given the highest possible nonlethal dose of amphetamine. These same doses did not augment the catecholamine-releasing properties of amphetamine in drum- or electric shock-stressed animals. It does not appear that stress potentiates the effects of amphetamine, as no evidence of excitation was obtained in stressed animals given amphetamine. It is postulated that amphetamine enhances the effects of stress."

Nisticò, G., Preziosi, P.: "Brain and liver tryptophan pathways and adrenocortical activation during restraint stress." *Pharmacol. Res. Commun.* **1**: 363-368 (1969).

G80,145/69

In rats, the increase in plasma corticosterone produced by restraint is associated with a rise in tryptophan pyrolase and a fall in brain 5-HT which are not correlated with the duration of the stress. The decrease in 5-HIAA during the first hour is followed by a progressive increase. Apparently, during stress "the tryptophan shunt from the serotonin to the kynurene pathway is almost abolished."

Rosecrans, J. A.: "Brain amine changes in stressed and normal rats pretreated with various drugs." *Arch. Int. Pharmacodyn. Ther.* **180**: 460-470 (1969). H18,475/69

In rats exposed to the stressor effect of vibration, 5-HT and NEP concentrations were determined in various areas of the brain. Apparently, NEP neurons were stimulated while the 5-HT systems were depressed. The latter, however, "were activated if this amine was depleted prior to stress, indicating the presence of a 5-HT negative feedback system. Lastly, there were differences observed in brain area responsiveness to stress, indicating the existence of different neuronal populations in the areas studied."

Bliss, E. L., Ailion, J.: "Response of neuromodulatory amines to aggregation and strangers."

J. Pharmacol. Exp. Ther. **168**: 258-263 (1969). H15,845/69

Aggregation of mice unaccustomed to each other caused a decrease in brain NEP and an acceleration of its catabolism. 5-HT levels remained unchanged, although 5-HIAA concentrations in the brain rose, indicating an increased catabolism of 5-HT. "Dopamine levels in brain and its catabolism were unaffected. At the same time no changes in norepinephrine metabolism could be detected in the adrenal, heart or spleen. The intermingling of strangers without aggregation also decreased brain norepinephrine. A more severe stress of footshock to rats not only diminished brain norepinephrine but also radically reduced catecholamine levels in the adrenal and spleen. These observations suggest that emotional disturbances activate the norepinephrine and serotonin systems in brain."

Scapagnini, U., Preziosi, P., Schaepdryver, A. de: "Influence of restraint stress, corticosterone and betamethasone on brain amine levels." *Pharmacol. Res. Commun.* **1**: 63-69 (1969). G80,096/69

In rats, the changes in brain 5-HT, dopamine and NEP provoked by restraint do not seem to result from the negative feedback effect of endogenous corticosterone.

Dixit, B. N., Buckley, J. P.: "Brain 5-hydroxytryptamine and anterior pituitary activation by stress." *Neuroendocrinology* **4**: 32-41 (1969). H8,973/69

Rosecrans, J. A., Sheard, M. H.: "Effects of an acute stress on forebrain 5-hydroxytryptamine (5-HT) metabolism in C.N.S. lesioned and drug pretreated rats." *Eur. J. Pharmacol.* **6**: 197-199 (1969).

H14,042/69

In rats exposed to the stress of horizontal oscillation, PCPA pretreatment and medial forebrain bundle lesions facilitated 5-HT turnover in the response to stress. Raphé lesions, on the other hand, prevented this facilitation of indoleamine turnover. "The results obtained were explained on the basis of an operative negative feedback system in stressed rats. The lack of a change in raphé lesioned rats further reinforced the concept that most forebrain 5-HT containing neurons are the result of axons extending from this nucleus."

Rosecrans, J. A.: "Effects of acute stress on forebrain 5-hydroxytryptamine metabo-

lism and pituitary adrenal function." *Eur. J. Pharmacol.* **9**: 170-174 (1970).

H22,576/70

"Male rats were paired according to equivalent spontaneous activity (curiosity), and were subjected to a more subtle stress of passive avoidance (one trial learning). This procedure consisted of determining how much time a rat would spend in a cage in which it had been shocked 24 hr previously. Pituitary-adrenal function was stimulated in rats who had learned this response, while non-learners exhibited no such change. In contrast, forebrain 5-hydroxytryptamine metabolism was reduced in learners and stimulated in non-learners."

Glowinski, J.: "Metabolism of catecholamines in the central nervous system and correlation with hypothalamic functions." In: Martini, L., Motta, M. et al. *The Hypothalamus*, pp. 139-152. New York and London: Academic Press, 1970. J12,266/70

Within a review on catecholamine metabolism in the CNS, a small section is devoted to the literature suggesting that in stress, noradrenergic and serotonergic neurons may play a role, especially in connection with the release of ACTH.

Billinson, M. R.: "Prematurity and low birth weight litters: a mechanism elicited by thermal stress." *Am. J. Obstet. Gynecol.* **108**: 970-974 (1970). H45,391/70

In rats, "thermal stress" increases 5-HT excretion which may be accompanied by premature delivery or low birth weight of the litters.

Thierry, A. M., Blanc, G., Glowinski, J.: "Effect of stress on the disposition of catecholamines localized in various intraneuronal storage forms in the brain stem of the rat." *J. Neurochem.* **18**: 449-461 (1971).

G82,745/71

Scapagnini, U., Moberg, G. P., Loon, G. R. van, Groot, J. de, Ganong, W. F.: "Relation of brain 5-hydroxytryptamine content to the diurnal variation in plasma corticosterone in the rat." *Neuroendocrinology* **7**: 90-96 (1971). H36,747/71

In rats, the 5-HT content of the hippocampus and amygdala exhibits a circadian rhythm which roughly parallels that of plasma corticosterone. PCPA, which blocks 5-HT synthesis, increases the a.m. and decreases the p.m. plasma corticosterone levels, so that the circadian variations are largely

eliminated. "The results suggest that 'serotonergic' neurons play a role in the diurnal fluctuation in pituitary-adrenal function."

Curzon, G.: "Effects of adrenal hormones and stress on brain serotonin." *Am. J. Clin. Nutr.* **24**: 830-834 (1971) (20 refs.).

Curzon, G.: "Relationships between stress and brain 5-hydroxytryptamine and their possible significance in affective disorders." *J. Psychiatr. Res.* **9**: 243-252 (1972).

G95,120/72

In rats, "immobilization stress caused a prolonged increase of pyrolase and a transient fall of brain 5-HT. These changes were largely prevented by previous adrenalectomy." Brain 5-HIAA increased, in both intact and adrenalectomized rats. These findings may have a bearing upon the pathogenesis of depression.

Elo, H., Tirri, R.: "Effect of forced motility on the noradrenaline and 5-hydroxytryptamine metabolism in different parts of the rat brain." *Psychopharmacologia* **26**: 195-200 (1972).

G93,807/72

Forced motility in a treadmill enhances 5-HT metabolism in the rat forebrain within one hour, and this is followed by an increase in the brain stem, especially the mesencephalon-pons medulla regions. The changes disappear almost completely after fifty minutes of rest. NEP metabolism is also increased under similar conditions in the rat brainstem.

McLeod, W. R., McLeod, M. F.: "Indoleamines and the cerebrospinal fluid." In: Davies, B., Carroll, B. J. et al., *Depressive Illness. Some Research Studies*, Sect. 3, pp. 209-225. Springfield, Ill.: Charles C Thomas, 1972. E10,507/72

Depressed patients, unlike those suffering from other psychiatric disorders, have subnormal 5-HIAA levels in the CSF. A positive correlation exists between the CSF 5-HIAA values and the plasma 11-OHCS in depressed patients, before and after the dexamethasone suppression test.

Vermes, I., Telegdy, G.: "Effect of intraventricular injection and intrahypothalamic implantation of serotonin on the hypothalamo-hypophyseal-adrenal system in the rat." *Acta Physiol. Acad. Sci. Hung.* **42**: 49-59 (1972).

J4,627/72

In rats, intraventricular injection of 5-HT did not change the basal corticosterone pro-

duction but inhibited the activation of the hypothalamo-pituitary-adrenocortical system by intraventricular volume increase and surgical stress. 5-HT implanted into the anterior or posterior hypothalamus had no effect on the activation induced by ether stress, but when placed into the medial hypothalamus, it abolished the increase in corticosterone secretion produced by ether, without altering the basal discharge. "Thus, serotonin may play a physiological role in the inhibition of the hypothalamo-hypophyseal-adrenal system and one of the sites of action is the medial hypothalamus." This view is supported by literature suggesting that the hypothalamic "serotonergic" system may inhibit the pituitary-adrenal axis, and that drugs blocking 5-HT synthesis or decreasing the brain 5-HT concentration facilitate the activation of the pituitary-adrenocortical system; MAO inhibitors, which increase brain 5-HT, decrease stress-induced adrenocortical activation.

Curzon, G., Joseph, M. H., Knott, P. J.: "Effects of immobilization and food deprivation on rat brain tryptophan metabolism." *J. Neurochem.* **19**: 1967-1979 (1972).

J19,890/72

"Withdrawal of food or immobilization both led to changes in rat brain tryptophan metabolism. Brain tryptophan and 5-hydroxyindolyacetic acid concentrations both increased while changes in 5-hydroxytryptamine were much smaller."

Scapagnini, U., Preziosi, P.: "Role of brain norepinephrine and serotonin in the tonic and phasic regulation of hypothalamic hypophyseal adrenal axis." *Arch. Int. Pharmacodyn. Ther.* **196** Suppl.: 205-220 (1972).

H56,654/72

Résumé of the literature and the extensive experiments of the authors and their co-workers led to the following main conclusions: (1) there is an adrenergic system in the brain that inhibits ACTH secretion. Drugs that release active catecholamines from nerve endings block ACTH discharge if they can pass the blood-brain barrier or are injected directly into the third ventricle or ME. Stressors deplete brain NEP and increase ACTH secretion. Admittedly, the amount of drugs necessary for inhibition is large, compared to the normal catecholamine levels present in the brain and hence their action is of doubtful physiologic significance. They may act merely by constricting the portal vessels so that CRF cannot reach an ade-

quate concentration in the adenohypophysis. Among the drugs used to explore the ACTH inhibitory adrenergic mechanism were: amphetamine, α -ethyltryptamine, L-dopa, tyramine, α -MT, guanethidine, FLA-63 (an inhibitor of dopamine- β -oxidase) and L-threo-dihydroxy-phenyl-serine or "DOPS," which selectively repletes NEP after depletion of NEP and dopamine by α -MT, phentolamine (an α -blocking agent), and so on. (2) 5-HT appears to regulate the circadian variations of ACTH secretion by the limbic system. Its concentration is particularly high in the raphé nuclei (containing the highest level of serotonergic cell bodies), particularly the amygdala and hippocampus, in which it shows circadian variations. Destruction of these nuclei abolishes the circadian plasma corticosterone rhythm.

Glowinski, J., Hamon, M., Héry, F.: "Regulation of 5-HT synthesis in central serotonergic neurons." *Symp. Drug Abuse and Metabolic Regulation of Neurotransmitter*, pp. 239-257. La Jolla, Calif., 1972.

J15,063/72

Review and personal observations on the role of 5-HT, especially in the central regulation of stress responses (about 50 refs.).

Bliss, E. L., Thatcher, W., Ailion, J.: "Relationship of stress to brain serotonin and 5-hydroxyindoleacetic acid." *J. Psychiatr. Res.* **9**: 71-80 (1972). G91,750/72

In mice and rats, a variety of stressors, "including foot shock, restraint, swimming, positioning on inverted pots, and residence in a noxious habitat, will increase the concentration of 5-HIAA in the brains," presumably as a result of an augmented metabolism of brain 5-HT.

Golda, V., Stránský, Z., Petr, R., Herink, J., Žáková, Z.: "Brain serotonin in stressed, adrenalectomized and septal rats." *Activ. Nerv. Sup.* (Praha) **14**: 215-217 (1972). J20,547/72

Vermes, I., Dull, G., Telegdy, G., Lissák, K.: "Possible role of serotonin in the monoamines-induced inhibition of the stress mechanism in the rat." *Acta Physiol. Acad. Sci. Hung.* **42**: 219-223 (1972). J6,598/72

Pharmacologic studies in rats suggest that "the inhibition of stress by monoamines is mediated via increased hypothalamic serotonin content."

Vermes, I., Telegdy, G., Lissák, K.: "Correlation between hypothalamic serotonin con-

tent and adrenal function during acute stress. Effect of adrenal corticosteroids on hypothalamic serotonin content." *Acta Physiol. Acad. Sci. Hung.* **43**: 33-42 (1973).

J9,322/73

Various stressors (surgical trauma, formalin, electroshock, histamine, cold, restraint, ether) decreased the 5-HT content of the hypothalamus in the rat, with a concurrent increase in plasma corticosterone, within thirty minutes of application. A single dose of corticosterone increased the plasma level of this hormone and the hypothalamic 5-HT content. It also restored the otherwise low 5-HT concentration in the hypothalamus of adrenalectomized rats. ACTH increased corticosterone secretion and hypothalamic 5-HT, but only in the presence of the adrenal. Apparently, "acute stress induces a biphasic change in the hypothalamic serotonin content. The first phase consists of a decrease of the hypothalamic serotonin content, which precedes the increase in plasma corticosterone level and seems to be independent of the pituitary-adrenal system, and a second phase characterized by an increase of the hypothalamic serotonin level and its return to normal."

Yuwiler, A., Geller, E., Schapiro, S.: "Effect of neonatal corticoids on tryptophan pyrolase and brain serotonin." In: Németh, S., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 215-228. Bratislava: Slovak Academy of Sciences, 1973.

E10,470/73

In newborn rats, a single injection of cortisol induces tryptophan pyrolase and diminishes both the 5-HT content of the brain and body growth. These results are discussed in relation to the function of tryptophan in stress.

Calogero, B.: "Variazioni del turnover delle amine biogene nel sistema nervoso centrale del ratto dopo stimolazione acustica" (Biogenic amine changes in the central nervous system following acoustic stimulation in the rat). *Minerva Otorinolaringol.* **23**: 55-60 (1973).

J4,054/73

Intense auditory stimulation causes significant changes in the catecholamine and 5-HT content of the temporal cortex, amygdala, and hypothalamus of the rat. "Serotonin may inhibit the transmission of impulses through the auditory pathway under protracted stimulation."

Yuwiler, A., Geller, E.: "Rat liver tryptophan oxygenase induced by neonatal corticoid

administration and its effect on brain serotonin." *Enzyme* **15**: 161-168 (1973).

J11,698/73

A single injection of cortisol into newborn rats prematurely induces tryptophan oxygenase in the liver, "with a concomitant reduction in serotonin concentration in the thalamic-hypothalamic and pontine areas of the brain. The ability of tryptophan to behave as a metabolic regulator may be important in the organism's response to stress."

Vermes, I., Telegdy, G.: "Effect of 5-hydroxytryptamine on stress-induced adrenal function in the guinea pig." *Acta Physiol. Acad. Sci. Hung.* **43**: 99-103 (1973).

J12,927/73

"The hypothalamic serotoninergic mechanism exerts an inhibitory action on the stress-induced increase of hypothalamo-pituitary-adrenal function in the guinea pig." 5-HT introduced into the lateral ventricle inhibited the adrenal corticoid secretion increased by surgical stress. After implantation of 5-HT crystals into the ME, basal secretion was unchanged, but the increase of adrenal corticoid secretion was prevented.

Vermes, I., Molnár, D., Telegdy, G.: "Hypothalamic serotonin content and pituitary-adrenal function following hypothalamic deafferentation." *Acta Physiol. Acad. Sci. Hung.* **43**: 239-245 (1973).

J12,931/73

In rats, partial or total deafferentation of the hypothalamus decreases the adrenal response to "ether stress" and concurrently diminishes hypothalamic 5-HT concentration. The findings support the concept that "serotonin plays an inhibitory role in the function of the hypothalamo-pituitary-adrenal axis, and indicate that serotoninergic fibres are reaching the hypothalamus from the anterior and antero-superior parts."

Vermes, I., Telegdy, G.: "Adrenal function following drug-induced alterations of the hypothalamic serotonin content." *Acta Physiol. Acad. Sci. Hung.* **43**: 105-114 (1973).

J12,928/73

In rats, PCPA lowers the hypothalamic 5-HT content and facilitates stimulation of corticosterone secretion by "ether stress." Nialamide increases hypothalamic 5-HT but blocks the adrenal response to stress. Reserpine lowers hypothalamic 5-HT and enhances the basal corticoid secretion. However, after "ether stress" there is no response either in hypothalamic 5-HT content or adrenal function. In any event, the results suggest

that "the changes induced in the stress mechanism by different drugs are related to their action on the hypothalamic serotonin level. Its increase inhibits, while its decrease facilitates, the stress-induced activation of pituitary-adrenal function."

Thierry, A. M.: "Effects of stress on the metabolism of serotonin and norepinephrine in the central nervous system of the rat." In: Németh, Š., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 37-53. Bratislava: Slovak Academy of Sciences, 1973. E10,456/73

In rats, stress induced by electroshock over a period of three hours activated both 5-HT and NEP neurons in various brain structures, increasing the turnover of these compounds. The same stress applied for only fifteen minutes activated central NEP neurons, apparently because 5-HT neurons are less sensitive to mild stress (31 refs.).

Radulovački, M.: "Comparison of effects of paradoxical sleep deprivation and immobilization stress on 5-hydroxyindoleacetic acid in cerebrospinal fluid." *Brain Res.* **60**: 255-258 (1973). J21,552/73

Anokhina, I. P., Zabrodin, G. D., Svirinovskii, I. E.: "Neurochemical mechanisms of formation of psychopathologic conditions due to emotional stress." *Zh. Nevropatol. Psichiatr.* **73** No. 12: 1825-1833 (1973) (Russian). J16,960/73

Studies on changes in catecholamine and 5-HT metabolism in various brain areas of rats exposed to different stressors.

Abe, K., Hiroshige, T.: "Changes in plasma corticosterone and hypothalamic CRF levels following intraventricular injection or drug-induced changes of brain biogenic amines in the rat." *Neuroendocrinology* **14**: 195-211 (1974). H86,427/74

In rats, "brain amines were depleted by pretreatment with either reserpine or 6-hydroxydopamine. In spite of the persistence of marked depletion of hypothalamic NE content, the basal circadian rhythm as well as stress-induced changes in both plasma corticosterone and hypothalamic CRF levels were preserved in almost the normal fashion. In addition, more than two-fold increases of brain amine concentration by pretreatment with a MAO inhibitor affected neither basal circadian rhythm nor a stress-induced increase in the plasma corticosterone. These observations suggest strongly that brain amines are of relatively little importance in

the central regulation of ACTH secretion in the rat." NEP, dopamine, carbachol and GABA were injected into the lateral ventricles in large doses, and all of them except GABA elicited a significant increase in ACTH discharge.

Koob, G. F., Annau, Z.: "Behavioral and neurochemical alterations induced by hypoxia in rats." *Am. J. Physiol.* **227**: 73-78 (1974). H89,535/74

In rats, hypoxia caused a decrease in the NEP content, but no change in the 5-HT concentration of the forebrain. In rats with electrodes implanted in the lateral hypothalamus, "self-stimulation rates increased while food and water intake decreased during the first 12 h and subsequently returned toward control levels... The results suggest a time-related activation of central adrenergic neuronal systems during exposure to hypoxia." The observation of a differential effect of hypoxia on NEP and 5-HT agrees with several earlier studies using other stressors (36 refs.).

Ellison, G. D., Bresler, D. E.: "Tests of emotional behavior in rats following depletion of norepinephrine, of serotonin, or of both." *Psychopharmacologia* **34**: 275-288 (1974). J9,987/74

Costa, E., Meek, J. L.: "Regulation of biosynthesis of catecholamines and serotonin in the CNS." *Annu. Rev. Pharmacol.* **14**: 491-511 (1974). J12,127/74

Review on catecholamine and 5-HT synthesis in the nervous system under various conditions, including stress. "Benzodiazepines (minor tranquilizers) block the increase in NE turnover produced by stress, in doses devoid of any effect on amine turnover in normal animals. One of the mechanisms discussed above might be directly affected by the benzodiazepines, but they might directly affect another system of neurons that in stress influence noradrenergic neurons" (161 refs.).

Modigh, K.: "Functional aspects of 5-hydroxytryptamine turnover in the central nervous system." *Acta Physiol. Scand. Supp.* **403**: 1-56 (1974). H88,890/74

Experiments in mice induced to fight after prolonged isolation showed that "the concentration of tryptophan and the accumulation of 5-HTP in brain were higher in the fighting animals than in control animals which remained isolated. The rate of depletion of 5-HT after inhibition of synthesis

was, however, almost identical in fighting and isolated animals. In conclusion, the increased synthesis of 5-HT occurring during fighting is probably secondary to the increase in concentration of tryptophan in brain, and occurs independently of the impulse activity in 5-HT neurons."

Ladisich, W.: "Stress und Serotoninstoffwechsel in verschiedenen Arealen des Zentralnervensystems der Ratte" (Stress affecting the serotonin metabolism in different regions of the central nervous system in the rat). *Arzneim. Forsch.* **24**: 1025-1027 (1974).

H88,829/74

In rats, electric footshock caused a pronounced increase in 5-HIAA in the raphe and septum, whereas 5-HT concentrations rose mainly in the septum, thalamus and hypothalamus. In general, "septum and raphe appeared to be the regions whose 5-HT metabolism was mostly changed by the stress of electric footshock."

Schildkraut, J. J.: "Biogenic amines and affective disorders." *Annu. Rev. Med.* **25**: 333-348 (1974).

J12,641/74

Review of the literature and personal observations indicate that "different subgroups of patients with depressive disorders may exhibit different specific abnormalities in the metabolism of norepinephrine or other biogenic amines," particularly dopamine and 5-HT. The relationship between stress and metabolic changes in these substances is considered, but not regarded as being of proven significance (119 refs.).

H99,235/75

In rats, restraint or cortisol increased hepatic tryptophan pyrolase activity and (in certain age groups) 5-HT and 5-HIAA concentrations in the brain.

Stern, W. C., Morgane, P. J., Miller, M., Resnick, O.: "Protein malnutrition in rats: response of brain amines and behavior to foot shock stress." *Exp. Neurol.* **47**: 56-67 (1975).

J23,635/75

"Regional brain levels of the amines and 5-hydroxyindoleacetic acid showed little change in normal rats following up to 90 min. of shock, whereas depletions of up to 50% occurred in chronically protein malnourished rats. These neurochemical changes in the chronically malnourished rats were pronounced in the diencephalon and in the midbrain-pons-medulla brain regions. Normal rats which were switched in adulthood to the low protein diet showed minimal decreases in brain amine and 5-hydroxyindoleacetic acid levels following foot shock. This suggests that the effects observed in the chronically malnourished rats reflect a developmental interaction and were not due to the diet being administered at the time of testing" (25 refs.).

Woolf, C. J., Laburn, H. P., Willies, G. H., Rosendorff, C.: "Hypothalamic heating and cooling in monoamine-depleted rabbits." *Am. J. Physiol.* **228**: 569-574 (1975).

H99,314/75

In rabbits, 5-HT inhibits the vasomotor response to "heat stress" and activates heat conservation during "cold stress." Presumably, "the integrity of the monoaminergic system is vital for the correct functioning of the hypothalamus in maintaining a constant body temperature."

Ladisch, W.: "Influence of stress on regional brain serotonin metabolism after progesterone treatment and upon plasma progesterone in the rat." *J. Neural Transm.* **36:** 33-42 (1975). J24,802/75

"When electric footshock was administered to ovariectomized rats pretreated with progesterone or its vehicle, there were generally higher 5-HT and 5-hydroxyindoleacetic acid (5-HIAA) concentrations after progesterone. 5-HT levels were significantly higher in thalamus, hippocampus, raphé, and frontal cortex, 5-HIAA rose significantly in hippocampus, raphé, and frontal cortex. Whereas after electric footshock alone the septum showed highest increases of 5-HT and 5-HIAA and hippocampus ranged last, after pretreatment with progesterone increases of 5-HT and 5-HIAA were least pronounced in septum but rather high in hippocampus."

Histamine. (See also our earlier stress monographs, p. xiii, and cf. Histamine under Hormones and Hormone-like Substances in the section on Characteristic Manifestations of Stress)

Selye, H.: "Further evidence in support of the alarm reaction theory of adrenal insufficiency." *Am. J. Physiol.* **119:** 400-401 (1937). 68,414/37

Brief description of observations which "lead us to assume that the liberation from the tissues of certain toxic metabolites with histamine-like pharmacological effect is the primary cause both of the alarm reaction and of adrenal insufficiency."

Guillemin, R., Fortier, C.: "Role of histamine in the hypothalamo-hypophyseal response to stress." *Trans. N.Y. Acad. Sci.* **15:** 138-140 (1953). B80,534/53

In rats pretreated with Phenergan and exposed to various "neurotropic" (sound, restraint) or "systemic" (cold, histamine) stressors, only histamine became incapable of causing an adrenal ascorbic acid discharge. "These results do not support the view that histamine may be an important factor and, in no way, an indispensable link in hypothalamo-pituitary alteration due to neurotropic

stress." They also show that histamine cannot be the only humoral agent responsible for pituitary stimulation during stress.

Schnitzer, A.: "Histamin und Stress" (Histamine and stress). *Münch. Med. Wochenschr.* **97:** 446-469 (1955).

J25,677/55

Histamine liberation is considered to be a characteristic manifestation of the alarm reaction and may cause sudden death in corticoid-deficient patients receiving short-wave therapy.

Korovnikov, K. A.: "Significance of enzymes activity alterations in pathogenesis." *Vopr. Med. Khim.* **9:** 137-142 (1963) (Russian).

G14,879/63

In rats the histamine content of the muscles during intensive muscular work or cooling decreased significantly, whereas that of the blood remained unchanged. The histaminase activity of the blood increased slightly.

Ganong, W. F., Lorenzen, L.: "Brain neurohumors and endocrine function." In: Martini, L. and Ganong, W. F., *Neuroendocrinology*, Vol. 2, pp. 583-640. New York and London: Academic Press, 1967.

E6,920/67

Extensive review on neurohormones, particularly catecholamines, 5-HT, acetylcholine, histamine, substance P, γ -aminobutyric acid and dopamine (about 250 refs.).

Makarov, I. A.: "Role of histaminemia in changes of the eosinophil count during stress." *Vrach. Delo No. 1:* 77-79 (1971) (Russian).

J19,053/71

Observations on the rat and man suggest that "histamin may be the cause of eosinopenia and eosinophilia. Local histaminemia is accompanied by eosinopenia, total by eosinophilia. It is concluded that poststress eosinopenia develops due to prevailing migration of eosinophils into tissues with an increased histamin content as compared with their mobilization from the bone marrow. Blocking of endogenous histamin leads only to mobilization of cells from the bone marrow causing [the] paradoxical character of the reaction."

Makarov, I. A.: "Role of the adrenals in the development of post-stress eosinopenia." *Ter. Arkh.* **44** No. 11: 53-58 (1972) (Russian).

H91,719/72

There is no evidence of a direct destruction of blood eosinophils by glucocorticoids. Ob-

servations in rats and patients suggest that stress eosinopenia is produced by "local freeing of endogenous histamin in a number of organs. Glucocorticoids play an auxiliary role of a creator of an appropriate gradient of histamin concentration in the blood and tissues causing migration of eosinophils in the tissue. This confirmed the fact of blocking eosinopenia by dimedrol premedication. A regular drop in the markedness of eosinopenia observed in stress in patients with considerable hypercorticism can be attributed to the increase of the level of natural antagonist of histamin—heparin in patients of such kind."

Acetylcholine. Mazzone, R., Sozio, N., Padoleccchia, N.: "Effetti della sensibilizzazione colinergica sulla sindrome reattiva allo 'stress'" (Effect of cholinergic sensitization on the syndrome reactive to stress). *Boll. Soc. Ital. Biol. Sper.* **36**: 157-159 (1960). J23,135/60

Cholinergic drugs increase reactivity to pain-induced stress in the rabbit. These and other experiments with eserine and atropine suggest that "the stress reaction develops in a zone sensitive to acetylcholine but not to atropine, and thus furnish indirect evidence of the role of this reticular formation in the organization of defense mechanisms."

Ganong, W. F., Lorenzen, L.: "Brain neurohumors and endocrine function." In: Martini, L. and Ganong, W. F., *Neuroendocrinology*, Vol. 2, pp. 583-640. New York and London: Academic Press, 1967. E6,920/67

Extensive review on neurohormones particularly catecholamines, 5-HT, acetylcholine, histamine, substance P, γ -aminobutyric acid and dopamine (about 250 refs.).

Avoidance schedules and other environmental stressors greatly sensitized rhesus monkeys to the pressor effect of infused *angiotensin II*.

Igarashi, T.: "Influence of sialoadenectomy and cyanide [as well as *parotin*] on the stress loop." *Shikwa Gaku* **71**: 1356-1370 (1971) (Japanese). J24,561/71

Balestreri, R., Bertolini, S., Elicio, N., Costa, S.: "Glucagone e funzione del sistema ipotalamo-ipofisocorticosurrenalico nell'uomo" (Glucagon and function of the hypothalamic-hypophyseal-adrenocortical system in man). *Boll. Soc. Ital. Biol. Sper.* **50**: 417-423 (1974). J24,412/74

Experiments on man suggest the possibility that *glucagon* might act as a releasing factor of CRF. [The authors admit that the evidence in favor of this interpretation is still very problematic (H.S.).]

VARIOUS MECHANISMS THE FIRST MEDIATOR

Ever since the first description of the G.A.S., one of the most intriguing problems concerning its mediation was the identification of the stimulus responsible for alerting the organism to the existence of danger or increased demand. For example, in the case of a local burn to a leg, or of fear, or of hemorrhage, what could be the first mediator carrying the same message of stress from the first target of the eliciting agent (the leg, the CNS, or the cardiovascular system) to the centers initiating the stereotyped G.A.S. response? We have learned a good deal about the subsequent links in this biologic chain reaction that permit the relay of information (through the hypothalamus, pituitary, adrenal and so on), but little progress has been made in understanding how the most diverse stimuli, initiated in different parts of the body, can communicate the same message: that a state of stress exists.

The first working hypothesis postulated that any demand upon any tissue would liberate some ubiquitous toxic metabolite, that is, a by-product of increased tissue activity of any kind.

Histamine was initially suspected to play this role, since it can be liberated from many tissues under the influence of diverse stimuli, and it produces increased capillary

permeability and shock such as are seen in acute stress. Also, it causes a particularly pronounced corticoid discharge and is especially toxic to adrenalectomized animals. However, antihistaminics failed to protect rats against neurotropic (sound, restraint) or systemic (cold) stressors, counteracting only the effects of histamine itself. Hence, it was concluded that histamine could not be the only humoral agent responsible for pituitary stimulation during stress.

Of course, it is by no means proven that the nonspecificity of the stress reaction is due to its invariable initiation by the same substance; it might be that the receptors in the regulating centers (for example, the hypothalamus) react stereotypically to a great number of chemical messengers brought to them by the blood whenever there is any kind of increased demand anywhere in the body. Indeed, we have no proof that the first mediating agent is a substance (or group of substances) rather than a deficiency of some vitally important blood constituent which is "used up" during any kind of biologic activity.

It was always tacitly assumed that, whatever it may be, the first mediator is blood-borne rather than relayed through afferent nerves. This view appeared to receive confirmation from our first experiments, in which we showed that if one limb of an experimental animal is amputated (under appropriate anesthesia) and then only the main arteries and veins are reconnected by catheters, a burn applied to the severed, and hence totally denervated, extremity still causes manifestations of stress in the body, to which it is now connected only by the bloodstream. Yet similar experiments performed subsequently on dogs in which all structures were transected at the mid-thigh level, leaving only the femoral artery and vein and the sciatic nerve intact, showed that burns applied to the isolated leg increased corticoid secretion into the adrenal vein, whereas this was not the case after severance of the nerve. From this it was concluded that "there is no evidence for the production in the wounded area of a substance which stimulates the pituitary-adrenal axis."

On the other hand, recent observations on parabiotically united rats showed that if one partner is restrained on a mobile cart which its twin can pull about, stress ulcers of the stomach develop in both twins. These findings were interpreted to indicate a blood-borne "transmittal of restraint-induced gastric ulcers by parabiosis"; however, it may be assumed that in the experiments both partners were under considerable stress.

It is somewhat disappointing that forty years after the first description of the alarm reaction—despite all that we have learned about the subsequent mediation of the stress response through the hypothalamus-pituitary-adrenal and the sympathetic nervous systems—we still know virtually nothing about the nature of the first mediator.

All future studies along these lines should take into account that, despite the stereotyped nature of the stress response itself, we have no reason to believe that the first mediator is necessarily always an excess or a lack of a single substance, or the result of nervous arousal. It must be remembered that nervous stimuli are certainly dispensable, since stress occurs under deep anesthesia or after deafferentation of the hypothalamus in mammals, as well as in lower forms of life that have no nervous system. It is quite conceivable that a stereotyped stress reaction can be produced through the most diverse means merely by deranging the homeostasis of biologic systems, which are notoriously labile. In this event, stress could be compared with fatigue or energy consumption, which likewise are nonspecific responses to any demand, be it pleasant or unpleasant. Also, like stress, fatigue or energy utilization may be localized in any region of the body, or generalized throughout more or less diffuse organ systems.

The First Mediator

(See also our earlier stress monographs, p. xiii)

Selye, H.: "Further evidence in support of the alarm reaction theory of adrenal insufficiency." *Am. J. Physiol.* **119**: 400-401 (1937). 68,414/37

Brief description of observations which "lead us to assume that the liberation from the tissues of certain toxic metabolites with histamine-like pharmacological effect is the primary cause both of the alarm reaction and of adrenal insufficiency."

Guillemin, R., Fortier, C.: "Role of histamine in the hypothalamo-hypophyseal response to stress." *Trans. N.Y. Acad. Sci.* **15**: 138-140 (1953). B80,534/53

In rats pretreated with Phenergan and exposed to various "neurotropic" (sound, restraint) or "systemic" (cold, histamine) stressors, only histamine became incapable of causing an adrenal ascorbic acid discharge. "These results do not support the view that histamine may be an important factor and, in no way, an indispensable link in hypothalamo-pituitary alteration due to neurotropic stress." They also show that histamine cannot be the only humoral agent responsible for pituitary stimulation during stress.

Egdahl, R. H.: "Pituitary-adrenal response following trauma to the isolated leg." *Surgery* **46**: 9-21 (1959). D96,659/59

In dogs, all leg structures were transected at the midthigh level, leaving only the femoral artery and vein and the sciatic nerve intact. Burns applied to the isolated leg increased corticoid secretion into the cannulated adrenal vein only as long as the nerve supply remained intact. "The adrenocortical stimulation which follows severe burns or operative trauma is dependent exclusively upon peripheral nervous impulses. There is no evidence for the production in the wounded area of a substance which stimulates the pituitary-adrenal axis."

Mach, W. J., Mach, C.: "Biogenese und Chemismus der 'first mediators of stress.' Vorläufige Mitteilung" (Biogenesis and chemistry of the "first mediators of stress." Preliminary report). *Ärzt. Forsch. [II]* **13**: 101 (1959). C78,761/59

Preliminary observations suggesting that there is no single "first mediator" of stress, but rather a group of substances which are probably anionic polycondensates containing various cyclic compounds.

Rose, K. D., Maca, R., Pace, D. M.: "Sterol synthesis by cells cultured on serum from heat-stressed chickens." *Proc. Soc. Exp. Biol. Med.* **108**: 282-285 (1961).

D89,507/61

"Young chickens subjected to heat stress at 102°F for 24 hours elaborate a stress factor into their blood stream. When serum from these animals is used as an adjuvant in a serum-balanced salt solution medium, cells grown on this medium accumulate large numbers of small lipid droplets within their cytoplasm." Possibly, this factor may account for the hypercholesterolemia characteristic of stress in vivo.

Jayle, M. F.: "Rôle du métabolisme des glycoprotéines dans la biogénèse de l'athérosclérose. Concept sur le 'syndrome général de l'agression'" (Role of the metabolism of glycoproteins in the biogenesis of atherosclerosis. Concept of the "general stress syndrome"). *Ann. Thér.* **14**: 11-22 (1963).

G63,439/63

Under various stress conditions, the plasma levels of fibrinogen and of the glycoproteins haptoglobin and seromucoid are characteristically increased; this may play an important part in stress-induced atherosclerosis. The common denominator of the diseases of adaptation and of stress responses may be a rise in these compounds which might thus correspond to the "first mediator." This interpretation might act as a valid focal point of Selye's "unitary concept" although the claims concerning the central role of the pituitary-adrenal axis are rejected.

Seidel, W., Lorenz, W., Doenicke, A., Mann, G., Uhlig, R., Rohde, H.: "Histaminfreisetzung beim Menschen und Stressulkus-Pathogenese" (Histamine liberation in man and the pathogenesis of stress ulcers). *Z. Gastroenterol.* **11**: 297-300 (1973).

J24,571/73

In man, the plasma histamine content rises under the influence of various stressors and may play an important role in the pathogenesis of stress ulcers.

Tran, T. A., Gregg, R. V.: "Transmittal of restraint-induced gastric ulcers by parabiosis in rats." *Gastroenterology* **66**: 63-68 (1974).

J9,758/74

Induction of gastric ulcers "in the parabiotic mate of a restrained rat implicates a humoral factor in the etiology" of this lesion. "One rat of a parabiosed pair was restrained

for 28 or 30 hr on a mobile cart which its unrestrained mate was free to pull about. All restrained animals showed gastric ulceration, and 15 of 17 unrestrained mates also devel-

oped gastric ulceration" (28 refs.). [It may be assumed, however, that the control animal was also under considerable stress under such conditions (H.S.).]

GENERAL ADAPTATION SYNDROME (G.A.S.) VS. LOCAL ADAPTATION SYNDROME (L.A.S.)

Whereas the G.A.S. is the general or systemic response to a stressor, the L.A.S. represents its local, or topical, equivalent. Obviously, nonspecific demands for adaptation may be limited to certain regions of the body (for example, inflammation, wound healing), but both specificity and localization are relative concepts: demands may be more, or less, specific in the type of response that they require, or the region of the body that they affect. Thus, not only limited topical responses to diverse agents, but even nonspecific reactions primarily limited to certain systems (cardiovascular, nervous, RES), may be regarded as examples of an L.A.S.

In all these cases, the L.A.S. may cause a G.A.S. Thus, a nonspecific local inflammatory response may mobilize the hypothalamus-adrenal-pituitary axis for systemic defense if the demands are of sufficient intensity to require general adaptive reactions. This same is true even if the L.A.S. selectively affects not a circumscribed body system, but the CNS, the immune system, or any other anatomically widespread, but functionally separable and delimited entity.

To take one of the most carefully studied examples of such interactions: an L.A.S. produced by local inflammation (such as a granuloma pouch) will result in a triphasic nonspecific L.A.S. If mild, this will remain largely topical, but if sufficiently intense, it will cause systemic stress phenomena. Conversely, the G.A.S., with its associated discharge of stress hormones (particularly glucocorticoids), will act back upon the L.A.S. and inhibit the inflammatory response. The pain induced by topical injury in the region of an L.A.S. will likewise have systemic manifestations and induce a G.A.S. which, in turn, can alter the pain threshold. Indeed, if a highly specific and quite localized stimulus is of sufficient intensity to affect the whole organism, it may also produce a G.A.S. (for example, intense white light affecting the retina or a particular sound acting upon the ear). However, in such cases a specific agent, and not the L.A.S., represents the cause of a G.A.S.

General Adaptation Syndrome (G.A.S.) vs. Local Adaptation Syndrome (L.A.S.)

(See also our earlier stress monographs, p. xiii)

Hardy, J. D., Goodell, H., Wolff, H. G.: "Studies on pain: measurement of the threshold for an alarm reaction in man and its relation to pain perception." *Science* **93**: 439-440 (1941). B26,756/41

In man a thermal stimulus that evokes a just perceptible change in skin resistance is considered to be the equivalent of a local

alarm reaction probably elicited by pain. "The threshold level of the alarm reaction appeared to be related to the emotional state of the subject at the time. The administration of an analgesic agent such as acetylsalicylic acid when large areas were exposed raised the alarm reaction threshold to the pain threshold, and in the case of alcohol, higher than the pain threshold."

Selye, H.: "The local adaptation syndrome (L-A-S)." *Proc. 19th Int. Physiol. Congr.*, p. 750. Montreal, 1953. B79,918/53

The similarity of the L.A.S. to the triphasic G.A.S. (illustrated in rats by the use of the granuloma pouch technique) is emphasized by the fact that, in the pouch, "the first stage of this response is initiated by phenomena of cell degeneration and necrosis. These are immediately followed by the typical manifestations of acute inflammation. The second stage is characterized by chronic inflammatory changes, while during the third stage, cellular degeneration and necrosis again become prominent." The L.A.S., like the G.A.S., is nonspecific in its causation but quite typical in its manifestations. Furthermore, a severe L.A.S. can initiate a G.A.S., and the G.A.S. can inhibit the L.A.S., primarily through excess secretion of glucocorticoids.

Selye, H.: "The part of inflammation in the local adaptation syndrome." *Rev. Can. Biol.* **12**: 155-176 (1953). A97,423/53

Description of the L.A.S. and its relation to the G.A.S. Both are nonspecific reactions comprising damage and defense; they are triphasic, with typical signs of "cross resistance" and "cross sensitization" during the second stage; both are singularly sensitive to "adaptive hormones" (ACTH, STH, corticoids); and if they develop simultaneously in the same individual, they greatly influence one another.

Selye, H.: "Sensitization of individual vascular territories to the antiphlogistic effect of hydrocortisone. An example of 'selective conditioning.'" *Circ. Res.* **2**: 53-59 (1954). B83,630/54

In rats, ligation of one iliac artery causes a latent circulatory disturbance, after which intraperitoneal dextran induces severe anaphylactoid edema only in the other extremities. Cortisol likewise inhibits this response most markedly in the region with diminished blood supply. On the other hand, a stronger irritant such as croton oil causes necrosis with surrounding inflammation especially in the vasoligated extremity. "It is tentatively assumed that both vasoligation and hydrocortisone facilitate the breakdown of tissue by croton oil; the irritation of the resulting necrotic tissue being then added to that of the injected irritant, inflammation is stimulated to such an extent that the circulatory disturbance and the hormone fail to inhibit it."

Selye, H.: "Nonspecific resistance." *Ergeb. Allg. Pathol. Pathol. Anat.* **41**: 208-241 (1961). C95,972/61

In a review on nonspecific resistance, special attention is given to the prevention of inflammatory changes and aggravation of necrosis in the L.A.S. by the concurrent production of the G.A.S. (85 refs.).

Selye, H.: "Interactions between systemic and local stress." *Br. Med. J.* May 22, 1954, pp. 1167-1170. B90,618/54

"Using the granuloma-pouch technique, it was shown that, depending upon circumstances, systemic stress can either inhibit or aggravate the topical damage caused by exposure of a limited tissue area to a pathogen—for example, a chemical irritant, such as croton oil.

"The antiphlogistic effect of stress is not merely due to increased secretion of cortisol-like hormones, since it is also observed in adrenalectomized animals maintained on (in themselves inactive) threshold doses of injected cortisol.

"The aggravation of topical tissue injury by systemic stress also depends only in part upon endogenously produced adrenal hormones; it is abolished by complete adrenalectomy, but not if suitable substitution therapy with antiphlogistic corticoids (cortisone, cortisol) is given.

"Both these effects of systemic stress upon topical tissue reactions can be delayed, becoming manifest only after the systemic stressor has ceased to act."

Selye, H., Tuchweber, B., Gabbiani, G.: "Prevention of cutaneous calciphylaxis by topical stress." *Arch. Dermatol.* **87**: 566-574 (1963). D40,219/63

"A variety of agents such as distilled water, mechanical trauma (pinching the skin with a hemostat), formaldehyde, croton oil, or histamine liberators (e.g., compound 48/80, polymyxin) selectively inhibit skin calcification at the point where they are applied within the challenged area. Histologic studies show a relationship between this form of skin calcification, the distribution of mast cells, and the deposition of iron."

Funk, G. A., Jensen, M. M.: "Influence of stress on granuloma formation." *Proc. Soc. Exp. Biol. Med.* **124**: 653-655 (1967). F77,633/67

"Mice subjected to sound stress or a combination of avoidance-learning stress and sound stress showed a highly significant decrease in their ability to produce foreign body granulomas against subcutaneously-implanted cotton pellets."

Machida, T.: "Luteinization of ovaries under stressful conditions in persistent-estrous rats bearing hypothalamic lesions." *Endocrinol. Jap.* **18**: 427-431 (1971). H49,947/71

In rats bearing a croton oil granuloma pouch, persistent vaginal cornification and corpus luteum formation occurred if the medial preoptic area was destroyed. When both the medial preoptic area and the suprachiasmatic nuclei were destroyed, persistent estrus likewise developed, but without corpora lutea. These and other findings "suggest that the preoptic-suprachiasmatic region of the hypothalamus, especially the suprachiasmatic nuclei, is involved in luteinization of ovaries in persistent-estrous rats following exposure to stressful stimuli."

Balint, G. A.: "Examination of the inflammatory effect of ricin with special reference to the endogenous corticosteroid

mobilisation." *Toxicology* **1**: 329-336 (1973).

J10,650/73

The topical arthritis produced by injection of ricin into the hind foot pad of the rat shows the phlogistic potency of the substance. When injected intraperitoneally, it increases plasma corticoids and causes degranulation of the adrenals with inhibition of the anaphylactoid edema induced by dextran in the same animal.

Balasz, T.: "Development of tissue resistance to toxic effects of chemicals." *Toxicology* **2**: 247-255 (1974). J13,976/74

Review and personal observation on the development of topical tissue resistance following repeated systemic treatment with drugs having a topical damaging effect. This phenomenon represents an instance of cross-resistance presumably related to the G.A.S. (32 refs.).

CONDITIONING

In stress research, we understand by "conditioning" merely the establishment of conditions necessary for an agent to act. It can be positive if the conditions permit an action, or negative if they prevent it. Positive conditioning by corticoids has also been referred to as a "permissive" action. The concept is by no means limited to the establishment of conditioned reflexes, although it includes these together with any other nervous, chemical or physical factors that affect the body's reactivity.

Probably the first clearcut demonstration of conditioning in this sense was carried out in 1941. At that time, it was shown that adrenalectomized rats respond to the stressor effect of trauma with hypo-, rather than with the usual hyperglycemia. Active adrenocortical extracts (synthetic glucocorticoids were not yet readily available) restored the blood sugar level of the adrenalectomized animals but caused no hyperglycemia at the dose levels used. However, such substitution therapy permitted trauma again to elicit the usual stress hyperglycemia, at the same time raising shock resistance. It was concluded that the metabolic changes of stress are dependent upon amounts of corticoids that are, in themselves, ineffective. During the subsequent three decades, innumerable additional examples of such positive conditioning by corticoids and other agents were demonstrated. Yet it was many years before it became generally understood that conditioning is not always positive, and certainly is not limited to corticoids. In fact, the entire concept of "pluricausal diseases" is based upon the realization that certain morbid changes are not produced by one agent but by the simultaneous activity of conditioning and evocative factors.

In view of the many misunderstandings generated by the pertinent publications, this topic will be discussed in detail in the following abstract section. It should be emphasized here, however, that excess corticoids, produced as a consequence of stress, can also produce changes by themselves, under ordinary circumstances, without the simultaneous agency of unusual conditioning factors.

Conditioning

(See also our earlier stress monographs, p. xiii)

Selye, H., Dosne, C.: "Influence of traumatic shock on blood sugar of adrenalectomized rats treated with adrenal cortical extract." *Proc. Soc. Exp. Biol. Med.* **48**: 532-535 (1941). A37,037/41

In adrenalectomized rats, trauma failed to cause the usual hyperglycemia of stress. Active corticoid extracts restored the low blood sugar of adrenalectomized animals to normal, but at the doses used, they did not raise it above this level, nor did they elicit hyperglycemia in intact controls. However, if these extracts were administered to adrenalectomized rats during stress induced by trauma, a significant hyperglycemia resulted and shock resistance was raised simultaneously. Manifestly, the metabolic changes of stress are, in themselves, dependent upon ineffective amounts of corticoids. [This is probably the first experimental observation supporting the concept of "conditioning" or "permissive" actions of corticoids (H.S.).]

Ingle, D. J., Ward, E. O., Kuizenga, M. H.: "The relationship of the adrenal glands to changes in urinary non-protein nitrogen following multiple fractures in the force-fed rat." *Am. J. Physiol.* **149**: 510-515 (1947).

B4,742/47

In adrenalectomized rats, multiple bone fractures caused no rise in urinary nitrogen excretion unless the animals were treated with maintenance doses of adrenal cortical extract (cortin). In untraumatized, adrenalectomized rats, cortin actually diminished nitrogen excretion. "The negative nitrogen balance which characteristically develops following fractures may require the presence of the adrenal cortical hormones but is not caused specifically by the increase in secretion of the cortical hormones which occurs during stress." [This is the type of experiment that subsequently led Ingle to coin the term "permissive action" for what had previously been known as positive conditioning (H.S.).]

Skelton, F. R.: "On certain factors conditioning the action of the pituitary-adrenal system." In: Christman, R. C., *Pituitary-Adrenal Function*, pp. 39-48. Washington: American Association Advancement Science, 1950.

B45,085/50

Ingle, D. J., Nezamis, J. E.: "Effect of stress upon glycosuria of force-fed depa-

creatized and of adrenalectomized-depancreas-
tized rats." *Am. J. Physiol.* **162**: 1-4 (1950).

B49,683/50

In mildly diabetic rats, some of which were adrenalectomized and treated with maintenance amounts of cortical extract to sustain preadrenalectomy levels of glycosuria, stress (formalin) decreased sugar excretion, especially after adrenalectomy. [This is an example of a "permissive action" of corticoids, since adrenalectomized, untreated rats did not exhibit this effect (H.S.).]

Ingle, D. J.: "The functional interrelationship of the anterior pituitary and the adrenal cortex." *Ann. Intern. Med.* **35**: 652-672 (1951).

B65,287/51

Review of numerous earlier experiments by the author which shows that corticoids sensitize for various effects of diverse agents without being independently responsible for the changes. The author describes this "permissive" action which we previously designated as "conditioning."

Engel, F. L.: "The significance of the metabolic changes during shock." *Ann. N. Y. Acad. Sci.* **55**: 381-393 (1952).

B74,810/52

Review of the literature and personal observations showing that many metabolic actions characteristic of the G.A.S. are due to the conditioning (or "permissive") effects of corticoids upon responses to stress. As early as 1941, it was shown by Selye and Dosne that the typical hyperglycemia of traumatic shock in rats is replaced by hypoglycemia after adrenalectomy but hyperglycemia can be restored by glucocorticoid extracts in doses which by themselves do not influence the blood sugar of untraumatized adrenalectomized animals (64 refs.).

Ingle, D. J.: "The role of the adrenal cortex in homeostasis." *J. Endocrinol.* **8**: xxiii-xxvii (1952).

B75,214/52

Review suggesting that "the adrenal hormones play a 'permissive' rather than causative role in certain diseases and in certain metabolic responses to stress." The many observations of undoubtedly conclusive experiments that support this interpretation show that even large doses of corticoids produce few pathologic lesions by themselves, but they do facilitate the effects of various pathogens. [A phenomenon which had previously been described as the "conditioning action" of hormones (H.S.).]

Selye, H., Jacot, B.: "On the effect of various steriods upon the extra-adrenal thy-

molytic action of ACTH." *Acta Endocrinol.* (Kbh.) **9:** 333-336 (1952). B62,780/52

In adrenalectomized and orchidectomized rats, the thymolytic action of cortisone is greatly enhanced by simultaneous administration of ACTH, which has no such effect under similar conditions if given in combination with DOC or estradiol. Apparently, the thymolytic action of cortisone is augmented (conditioned) by ACTH, which has no direct effect on the thymus.

Ingle, D. J.: "The role of the adrenal cortex in homeostasis." In: Yoffey, J. M., *The Suprarenal Cortex*, pp. 177-189. London: Butterworths 1953. B83,030/53

Recapitulation of the author's earlier experiments indicating that, during stress, adrenalectomized rats maintained on a fixed amount of cortical extract may show signs of adrenal deficiency because of increased corticoid requirements. "There is no doubt that the presence of the adrenal cortical hormones is essential for the overt manifestation of such diseases as diabetes mellitus, hypertension, prostatic cancer, etc. It may be possible to explain much of the evidence which Selye offers in support of his hypothesis in terms of the 'permissibility' of cortical hormone action."

Engel, F. L.: "The adrenal cortex and the metabolic response to stress." *J. Clin. Endocrinol.* **15:** 1555-1558 (1953).

B88,627/53

Theoretical discussion on the relative merits of the "permissive" and "conditioning" roles of corticoids in stress reactions. These are practically indistinguishable from each other but appear to be more important than the direct effects of these hormones upon the tissues.

Engel, F. L.: "General concepts of adrenocortical function in relation to the response to stress." *Psychosom. Med.* **15:** 565-571 (1953). B88,336/53

Review of the literature on the G.A.S. in relation to the role of conditioning factors in determining responses to corticoids. Some authors emphasize conditioning, others the direct action of corticoids. "In all likelihood, the truth probably lies somewhere in between these two views, with the adrenal and stress responses being so inextricably interwoven and interdependent as to be essentially inseparable" (31 refs.).

Burns, T. W., Engel, F. L., Viau, A., Scott, J. L. Jr., Hollingsworth, D. R., Werk, E.:

"Studies on the interdependent effects of stress and the adrenal cortex on carbohydrate metabolism in man." *J. Clin. Invest.* **32:** 781-791 (1953). B84,911/53

Observations on the effect of cortisone during stress, as well as after insulin or glucose administration, "are considered to be compatible with the concept that there is an interaction between stress and adrenal hormone in modifying carbohydrate metabolism. They are not reconcilable with the view that the metabolic alterations during stress are direct consequences of adrenal cortical hypersecretion."

Selye, H.: "'Conditioning' versus 'permissive' actions of hormones." *J. Clin. Endocrinol. Metab.* **14:** 122-127 (1954) (12 refs.).

B86,400/54

Review of the earlier literature which led the author to the concept that the main action of corticoids is not their direct effect upon the target organ, but their ability to "condition" tissues to respond to stimuli, and that, conversely, the action of specific stimuli is altered by corticoids. Such conditioning increases or decreases stress responses. The term "permissive" is also acceptable, but only for what we have called "positive conditioning," that is, when a response is made possible as a result of corticoid actions. The principle of conditioning (first formulated in 1936) has been repeatedly illustrated by many experimental examples and is summarized in Figure 23 (p. 1144).

Ingle, D. J.: "Permissibility of hormone action. A review." *Acta Endocrinol.* (Kbh.) **17:** 172-186 (1954). C789/54

Review of experimental observations that leads the author to the conclusion that "the conditions under which the term permissive is applied are as follows: 1. The metabolic response to a stimulus occurs in the presence of an endocrine organ. 2. The response fails to become overt when the organ is removed and no replacement therapy is given. 3. The response is again elicited by an appropriate stimulus when a steady intake of hormone is substituted for an endocrine organ." Although earlier experiments have led to the designation of these same observations as "humoral conditioning," this is not considered a valid reason for replacing "humoral" with "permissive."

Ingle, D. J.: "Permissive action of hormones." *J. Clin. Endocrinol. Metab.* **14:** 1272-1274 (1954). B98,701/54

Arguments in favor of replacing the term

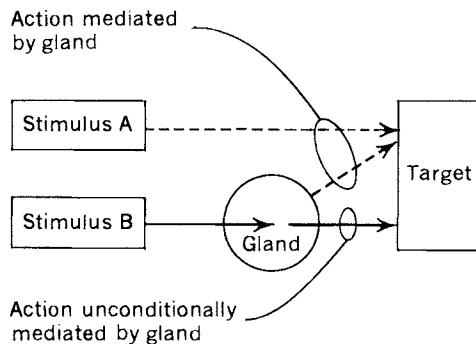

Figure 23. Conditional and unconditional actions of stimuli, the effects of which depend upon an endocrine gland. Supposing a stimulus acts on a target organ in the presence, but not in the absence of an endocrine gland, two possibilities exist: *A.* the stimulus acts directly on the target organ, but only if the latter is maintained in a responsive condition by constant hormonal impulses, which it receives from the gland (interrupted lines), *B.* the stimulus has no direct effect upon the target, but merely induces the gland to release a hormone which, in turn, acts upon the target (solid lines). (Reproduced from *J. Clin. Endocrinol. Metab.* 14 (1954) by permission of the J B Lippincott Company.)

"conditioning" by "permissive." Reconsideration of published data leads the author to the conclusion that "Selye and I agree that the word 'permissive' is not adequately descriptive of the facts. I prefer the term 'supporting,' but neither it nor any other word that has been suggested has quite the desired connotation. Selye suggests the term 'conditioning' on the grounds that the presence of hormone is one of a pattern of conditions under which the response will occur." However, the view that "extra-adrenal mechanisms may require the presence of the cortical hormones to support normal responsiveness, is in my opinion not weakened by evidence that the extent of response can also be modified by a change in titer of these hormones."

Selye, H.: "Sensitization of individual vascular territories to the antiphlogistic effect of hydrocortisone. An example of 'selective conditioning.'" *Circ. Res.* 2: 53-59 (1954).

B83,630/54

In rats, ligation of one iliac artery causes a latent circulatory disturbance, after which dextran ip induces severe anaphylactoid edema only in the other extremities. Cortisol likewise inhibits this response most markedly in the region with diminished blood supply. On the other hand, a stronger irritant such as croton oil causes necrosis with surrounding inflammation, especially in the vasoligated extremity. "It is tentatively assumed that both vasoligation and hydrocortisone facil-

tate the breakdown of tissue by croton oil; the irritation of the resulting necrotic tissue being then added to that of the injected irritant, inflammation is stimulated to such an extent that the circulatory disturbance and the hormone fail to inhibit it."

Selye, H.: "Selective alteration of certain ACTH and glucocorticoid effects by androstan derivatives." *Metabolism* 4: 403-415 (1955).

C2,007/55

In rats, "the actions of ACTH upon its primary target, the adrenal, can be altered, both quantitatively (inhibition of hypertrophy) and qualitatively (formation of hyaline-cell inclusions), by concurrent treatment with certain androstan derivatives (MAD, methyltestosterone, testosterone). These same steroids can also alter the pattern of the peripheral changes produced by ACTH in its ultimate targets. Some effects of ACTH treatment (catabolism) are diminished, while others are enhanced (preputial gland stimulation) and yet others may remain essentially unaltered (antiphlogistic, thymolytic effects), in the same animal." Thus, one hormone can selectively condition certain targets for the actions of another.

Ingle, D. J.: "The role of the adrenal cortex in homeostasis." *Pediatrics* 17: 407-413 (1956).

C13,045/56

Several types of experiments on rats show that "at least some responses to stress occur full-blown in adrenalectomized animals

given normalizing doses of cortical hormones, although the response does not become overt in the animal with adrenal insufficiency. This can be regarded as an example of the permissive or supporting role of hormones." Alternatively, tissue responsiveness to corticoids may be augmented by stressors. Hence, the "diseases of adaptation" may not be the direct effect of adrenocortical dysfunction (20 refs.).

Ingle, D.: "Current status of adrenocortical research." *Am. Sci.* **47**: 413-426 (1959).

D41,791/59

In rats, excess sodium chloride intake can elicit hypertension, but concurrent treatment with corticoids greatly accelerates its development. "This is the basis for my claim that the primary cause of pathology in the Selye experiments is the trouble the animal is having with electrolytes: the sodium-retaining steroids play a 'conditioning' role—to use Selye's word—when they are present."

Ingle, D. J., Ingle, D. J.: "The relationship of the adrenal glands to diseases of adaptation." *Acta Endocrinol. (Kbh.)* **50** Supp.: 89-92 (1960). C92,395/60

Recapitulation of the authors' experiments on the permissive conditioning action of glucocorticoids. The production of diseases of adaptation by excess corticoid secretion during stress is questioned on the basis of the assumption that, in stress, more corticoids are utilized for resistance, which is also why Cushingoid symptoms do not occur. Still, the authors admit that some symptoms of corticoid excess are evident during stress. They conclude that "suppression of some but not all symptoms of hypercorticalism by stressors may be related to the well known fact that the need of the organism for cortical hormones is greatly increased by severe stress." [It is difficult to see how removal of excess corticoids by increased utilization could selectively annul only some of their effects (H.S.).]

Ingle, D. J.: "The effect of some stressors on steroid diabetes in the rat." *Diabetes* **9**: 394-395 (1960). C94,537/60

Several stressors (tumor implant, restraint, formaldehyde) suppress the glycosuria caused by large doses of cortisone in force-fed rats. [Here the concept of "permissive" actions is not invoked (H.S.).]

Ingle, D. J.: "The relationship of adrenal cortex functions to disease." *Am. J. Proctol.* **12**: 245-252 (1961). D12,583/61

Detailed discussion on the importance of conditioning (permissive effect) in stress-induced ulcerations (25 refs.).

Corson, S. A.: "Neuroendocrine and behavioral response patterns to psychologic stress and the problem of the target tissue in cerebrovisceral pathology." *Ann. N. Y. Acad. Sci.* **125**: 890-918 (1966). G36,865/66

Review of the technical literature on the conditioning factors determining the particular target tissue which will respond to physiologic or psychologic stressors.

Selye, H.: "Pluricausal diseases." *Exp. Med. Surg.* **24**: 191-209 (1966).

G32,043/66

The pluricausal diseases are divided into "conditioned lesions," in which the action of the primary pathogen is merely enhanced or diminished by the conditioner, and "synthetic lesions," in which appropriate combinations of the most diverse, and in themselves ineffective, potential pathogens produce identical lesions. These possibilities are schematically illustrated in Figure 24 (p. 1146).

Selye, H.: "Malattie da cause molteplici" (Pluricausal diseases). *Osped. Ital. Chir.* **16**: 375-399 (1967). G46,780/67

Italian translation of the English article.

Stevenson, I.: "Single physical symptoms as residues of an earlier response to stress." *Ann. Intern. Med.* **70**: 1231-1237 (1969).

J22,514/69

"Single physical symptoms often persist after a general reaction to stress and after the other symptoms of the general reaction have subsided.... Factors influencing the persistence and location of one symptom after a general reaction to stress form only one group of the relevant causal factors in these disorders" (15 refs.).

Hinkle, L. E. Jr.: "The concept of 'stress' in the biological and social sciences." *Sci. Med. & Man* **1**: 31-48 (1973).

J10,855/73

A review of the history of the stress concept and the diseases of adaptation. Accumulated evidence "has confirmed that a large proportion of the manifestations of disease are produced by reaction of the host and not directly by the 'causal agents' of disease, and that the components of the host's reactions are not in themselves 'specific' to any given 'causal agent'; it has confirmed that reactions of people to other people, or to the social environment may in-

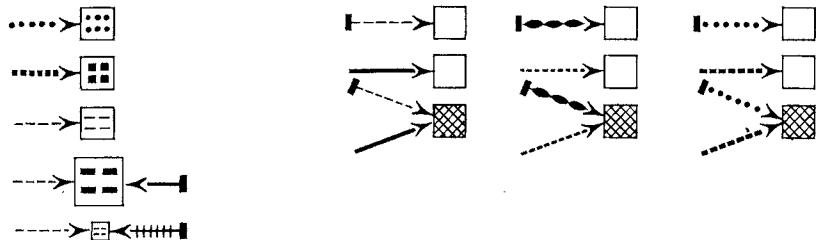

Figure 24. Left. *Conditioned lesions*. Each agent produces different lesions whose development is readily suppressed or aggravated (without being qualitatively altered) by conditioning factors. Right. *Synthetic lesions*. Identical prototypes of lesions are elicited by several combinations of in themselves inactive, essentially different agents. (Reproduced from *Exp. Med. Surg.* 24 (1966) by permission of Brooklyn Medical Press.)

fluence any physiological process or any disease." Yet the author doubts that the stress concept can provide an adequate explanation for these phenomena. He feels that "one who undertakes to criticize a theory such as the theory of stress, and to indicate that it may be inadequate today, is fortunately not required to put forward a new theory to replace it. Possibly no new theory is needed." On the other hand, the importance of conditioning factors which make stress pathogenic is clearly recognized by the statement: "One will, indeed, see hard

working, striving, impatient men who drop dead suddenly at the end of a hard day's work. If one performs population studies on a prospective basis, one is likely to find that this occurs most frequently among middle-aged and elderly men who are hyperlipidemic, who have elevated blood pressures, who have a long history of smoking cigarettes, and who have evidence of disorders of their cardiac conduction systems; and it will be very rare, indeed, that such a sudden death will be found in a healthy young woman who has none of these conditions."

THE THREE PHASES OF THE G.A.S., ADAPTATION ENERGY, AGING

The triphasic nature of the G.A.S., the concept of adaptation energy, and the theory of aging are so closely interdependent that it is most convenient to discuss them conjointly here.

Both the G.A.S. and the L.A.S. evolve in *three stages*: the alarm reaction, the stage of resistance and the stage of exhaustion. When the concept was first developed, we adopted this terminology because it seemed that the first stage represents a call to arms of the organism's defensive forces; this gradually leads to resistance when adaptation to the evocative stressor is acquired; but eventually the ability to resist is exhausted and death ensues. In the systemic form of this reaction (G.A.S.), the first manifestations to be observed during the alarm reaction are: catabolism of tissues

(with loss of body weight), pronounced thymic lymphatic involution, signs of adrenal hyperactivity (loss of lipid secretion granules from the cortex and of chromaffin material from the medulla, with hyperemia and mitotic proliferation), acute gastrointestinal erosions (which subsequently became known as stress ulcers), eosinopenia, lymphopenia and polynuclear leukocytosis.

During the stage of resistance of the G.A.S. all these changes disappear or become much less pronounced, notwithstanding continued treatment with the same dose of the evocative stressor. However, despite adequate caloric intake and an apparently perfect adaptation, resistance is eventually exhausted, and changes very similar to those of the alarm reaction reappear.

The objective manifestations of the L.A.S. likewise develop in three stages: the local alarm reaction is mainly characterized by degeneration, necrosis and/or atrophy as well as acute inflammation, hypertrophy and hyperplasia of the topically-injured area; this is followed by chronic inflammation, hypertrophy and hyperplasia of tissues at the site of irritation; and eventually there is degeneration, necrosis and/or atrophy owing to local tissue breakdown, corresponding to the local stage of exhaustion.

Most of our work on the L.A.S. was performed with the granuloma pouch technique. This lends itself particularly well to the demonstration of the local triphasic reaction. The wall of the inflammatory pouch is at first acutely damaged and inflamed, but under continued irritation it becomes sclerotic and extremely resistant to local irritation; finally, if the topical stressor is sufficiently severe, tissue breakdown results in the eventual perforation of the pouch wall and evacuation of the exudate and irritant.

Both the G.A.S. and the L.A.S. are essentially nonspecific: they can be provoked by a great variety of agents although they act respectively on the whole body or on one part of it. A good deal has been learned about the mechanism that ensures the local or systemic mobilization of defense forces, followed by the acquisition of resistance; but we know little about the causes of systemic or local exhaustion.

The maxim, "The length of life depends inversely on the rate of living," or in more popular terms, "The candle of life does not last long if you burn it at both ends," was accepted on empirical evidence much before the G.A.S. concept could have been clearly formulated. The phenomenon referred to is reminiscent of *aging* and fatigue, but we can only speculate upon its mechanism. We have all noticed that, like an inanimate machine, a living organism (or any part of it) shows wear and tear as a consequence of continuous demands upon it. But wear and tear cannot be wholly responsible for the aging process, since despite uninterrupted exposure to a stressor, at least partial adaptation can be maintained for a long time. Possibly, most of the innumerable reactions involved in adaptation are reversible, leading to soluble end-products that can be metabolized or excreted, thereby assuring recovery. However, a small percentage of these reactions may produce metabolites (possibly in the form of virtually insoluble precipitates of calcium deposits, cross-linked proteins, amyloid or "aging pigments") that may represent some of the wastes of life. Their accumulation in the cells and intercellular spaces increasingly interferes with normal function, leading eventually to death.

Normal immune function decreases with age, while autoimmunity increases. The latter observation is interesting both because of its interpretation of aging as being caused by the accumulation of undesirable waste products (here antigen = antibody complexes), and because both systemic stress and aging result in thymic lymphatic involution. Neonatal thymectomy produces changes characteristic of premature aging.

This interpretation appears to be compatible with the observation that, following

comparatively short exposure to stressors, simple rest will result in near-complete recovery, perhaps because most of the chemical wastes of short-term stress can be metabolized or excreted. However, after a whole lifetime of adaptation to the countless demands of homeostasis under constantly changing conditions, the destruction and elimination of wastes can no longer keep pace with their accumulation, probably representing what we usually consider to be tissue aging.

This concept is also quite consonant with the view that actually we have two types of *adaptation energy*: one superficial, readily accessible in times of need, but also quickly exhausted; the other deep-seated, more slowly mobilized and virtually irreplaceable. During the alarm reaction, we can call upon immediately accessible superficial adaptation energy, but of this we have only small amounts that are rapidly used up unless the demand is sufficiently mild to allow time for the mobilization of deep-seated adaptation energy and transition to the stage of resistance. Yet even this form of adaptation is not limitless, and eventually leads to exhaustion. This final stage is characterized by local tissue necrosis in the L.A.S., and in the G.A.S. by premature death if the organism is faced with fatally severe stressors, or by death at the end of a normal lifespan under ordinary conditions.

In the light of these considerations the L.A.S. and G.A.S. could be considered, respectively, as the topical and systemic telescoped equivalents of a normal lifespan. As time passes, the excessive sensitivity and adaptability of childhood is followed by the lesser responsiveness, but greater resistance, of adulthood and eventually by tissue breakdown and degeneration, with loss of adaptability, and death.

In closing this speculative section, let us call attention to the phenomena of cross-resistance and cross-adaptation, which have already been considered in describing responses to two or more simultaneously-applied stressor agents. Truly nonspecific adaptive phenomena can usually lead to cross resistance against nonspecific effects of other stressors; but if the demands made by one agent are excessive, the exhaustion of adaptation energy necessarily diminishes the ability to activate additional adaptive resources.

The concept of adaptation energy is necessarily vague, since we have no way of identifying it directly and must rely upon resistance itself to estimate its quantity. However, if we attempt to express these same thoughts in more precise chemical terms as "the accumulation of damaging waste products," we are more likely to arrive at an objective indicator of adaptability, adaptation energy meaning the ability to get rid of these wastes that, in the final analysis, may be the cause of local or systemic exhaustion in the L.A.S. and G.A.S., as well as of the phenomenon of aging.

These interpretations would also appear to be applicable to various forms of experimental progeria and premature aging, such as those induced by x-irradiation or chronic vitamin D overdosage, which undoubtedly lead to insoluble metabolic wastes, such as protein metabolites or calcium deposits.

The Three Phases of the G.A.S., Adaptation Energy, Aging

(See also our earlier stress monographs, p. xiii)

Pearl, R.: *The Biology of Death*. Philadelphia: J. B. Lippincott, 1922.

E295/22

Enunciation of hypothesis that "the length of life depends inversely on the rate of living."

Selye, H.: "Thymus and adrenals in the response of the organism to injuries and intoxications." *Br. J. Exp. Pathol.* 17: 234-248 (1936). 36,032/36

First detailed description of the "alarm reaction," characterized by adrenocortical enlargement with acute loss of lipids, thymic-lymphatic atrophy and loss of body weight. The response appears to be elicited by any damaging agent (surgical injuries, exposure to cold, restraint, fasting for forty-eight hours or more, large doses of atropine, morphine, formaldehyde, or EP). Adrenalectomy and, to a lesser extent, hypophysectomy prevent the thymus involution. "The changes caused by a drug when it is given for the first time will subside later in spite of the continued administration of this drug" but greatly shorten survival. Perhaps the adrenal enlargement, loss of body weight and the other manifestations of the alarm reaction enable the organism "to meet critical situations more efficiently."

Dosne, C., Dalton, A. J.: "Changes in the lipid content of the adrenal gland of the rat under conditions of activity and rest." *Anat. Rec.* **80**: 211-217 (1941). 81,198/41

In rats, treatment with various stressors (cold, formaldehyde) causes an initial hypertrophy and lipid loss from the adrenal cortex during the alarm reaction. This is followed by lipid storage during the resistance stage and a second period of lipid loss during the stage of exhaustion of the G.A.S.

Reid, D. D.: "Some measures of the effect of operational stress on bomber crews." *Air Ministry, A.P.* **3139**, pp. 245-258. London: HMSO, 1947. B27,155/47

Reid, D. D.: "Fluctuations in navigator performance during operational sorties." *Air Ministry, A.P.* **3139**, pp. 321-329. London: HMSO, 1947. B27,164/47

Pilots making repeated sorties over Germany during World War II showed an initial intense anticipatory anxiety with steady deterioration in efficiency on the outward journey, particularly over the enemy coast and on approaching the target. This was maximal in the phase of heavy enemy fighter opposition and persisted as long as the aircraft was over enemy territory. Following numerous sorties, neurotic manifestations and breakdown eventually occurred.

Nigeon-Dureuil, M., Rabinowicz, M., Rahandraha, T., Ratsimamanga, A. R.: "Signification des variations pondérales et biochimiques transitoires de l'hypophyse, de la surrénale et du thymus, au cours d'un stimulus continu de moyenne intensité, le froid à 6°" (Significance of the transitory ponderal

and biochemical variations of the hypophysis, adrenal, and thymus during exposure to a continuous stimulus of moderate intensity, cold at 6°). *C.R. Soc. Biol. (Paris)* **146**: 370-377 (1952). B75,131/52

In rats exposed to moderate cold, the various manifestations of the G.A.S. show periodic fluctuations, probably due to successive discharges and storage of hormones. The thymus allegedly can store corticoids and thereby provide an additional reserve. [The authors promised subsequent papers in which these concepts would be further elaborated (H.S.).]

Selye, H.: "The part of inflammation in the local adaptation syndrome." *Rev. Can. Biol.* **12**: 155-176 (1953). A97,423/53

Description of the L.A.S. and its relation to the G.A.S. Both are nonspecific reactions comprising damage and defense; they are triphasic with typical signs of "cross resistance" and "cross sensitization" during the second stage; both are singularly sensitive to "adaptive hormones" (ACTH, STH, corticoids); and if they develop simultaneously in the same individual, they greatly influence one another. The characteristics of the three phases in the L.A.S. are illustrated by Figure 25 (p. 1150).

Selye, H.: "The 'critical period' in the development of inflammation." *Acta Physiol. Lat. Am.* **3**: 188-193 (1953). B85,700/53

In rats with granuloma pouches, pretreatment of a circumscribed area with a threshold dose of an irritant causes topical resistance to subsequent administration of an otherwise fully effective dose of the same agent. This corresponds to the phase of resistance of the L.A.S.

Flückiger, E., Verzár, F.: "Überdauern der Adaptation an niedrigen atmosphärischen Druck, nachgewiesen an der Wärmeregulation" (Body temperature regulation indicating retained adaptation under reduced oxygen tension). *Helv. Physiol. Pharmacol. Acta* **11**: 67-72 (1953). B92,392/53

In rats exposed to reduced oxygen tension, the body temperature drops but returns to normal after three to four days. "This 'retained adaptation' is not dependent on the presence of the adrenals. The phenomenon can also be seen in adrenalectomized rats kept alive with corticoids."

Perlman, R. M.: "The aging syndrome." *J. Am. Geriatr. Soc.* **2**: 123-219 (1954). C34,471/54

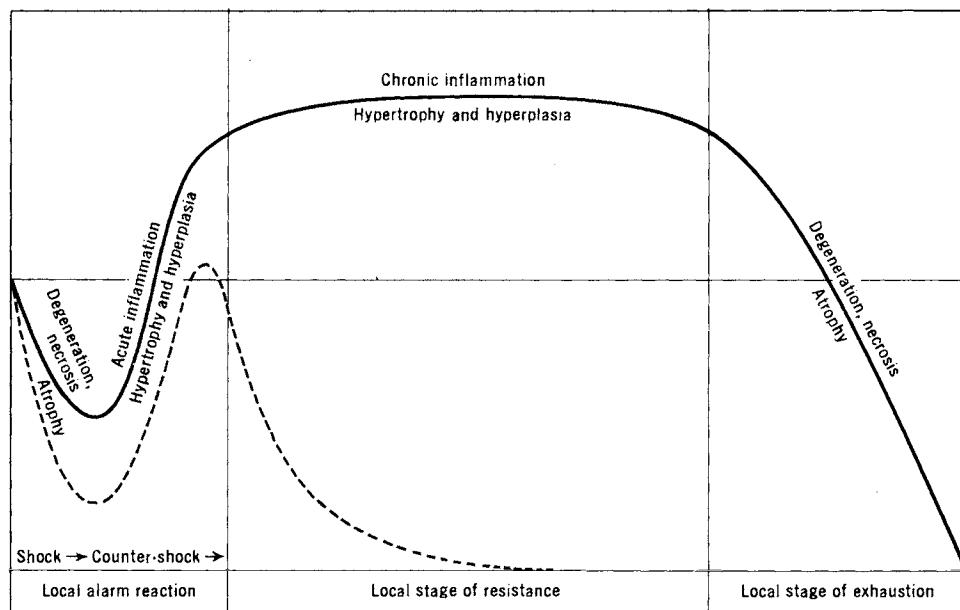

Figure 25. Typical changes in morphologic structure and topical resistance, as they occur during the three stages of the L.A.S. The heavy line represents "specific resistance," the interrupted line, "cross-resistance." (Reproduced from *Rev. Can. Biol.* 12 (1953) by permission.)

"Data are furnished to develop the thesis that aging in man is, essentially, a disease syndrome arising out of the struggle between environmental stress versus biologic resistance and relative adaptation to the effects of stressor agents."

Selye, H.: "Stress and disease." *Geriatrics* 10: 253-261 (1955). B98,390/55

Kountz, W. B., Kheim, T., Ackermann, P. G., Toro, G.: "Nutritional deficiency due to age and physiologic stress; its control by food and hormones." *J. Am. Geriatr. Soc.* 4: 1005-1020 (1956). J25,131/56

Jones, H. B.: "A special consideration of the aging process, disease, and life expectancy." *Adv. Biol. Med. Phys.* 4: 281-337 (1956). J22,383/56

Still, J. W.: "Physiology. The physiology of aging—a research approach." *J. Wash. Acad. Sci.* 48: 224-229 (1958).

G62,259/58

Emphasis upon similarities between the three phases of the G.A.S. and the three stages of life. The response to stress, and particularly the duration of the resistance phase, is characteristically shortened in the aged.

Curtis, H. J., Gebhard, K. L.: "Peaceful uses of atomic energy." *Proc. 2nd Int. Conf.* 22: 53 (1959). J11,912/59

In mice, chronic treatment with nitrogen mustard, bacterial toxins, turpentine or other stressors did not detectably shorten lifespan.

Selye, H., Prioreschi, P.: "Stress theory of aging." In: Shock, N. W., *Aging. Some Social and Biological Aspects*, No. 65, pp. 261-272. Washington: American Association Advancement Science, 1960. C76,248/60

Theoretical discussion of the relationship between aging and the exhaustion phase of the G.A.S. in the case of systemic stress, and that of the L.A.S. in the case of topical chronic stress. Premature aging of the entire organism occurs upon long continued exposure to severe stress, as in concentration camp survivors. As examples of local aging, the gradual disintegration of granuloma pouches exposed to strong local irritants and the disintegration of the "central cords" in tissue scaffolding tubes unable to rid themselves of accumulating wastes are mentioned. "The life span of an individual seems to depend on two factors: the quantity of adaptation energy that he receives at birth and the rate at which he spends it." [The concept of

accumulating "chemical scars" in the form of waste products that increasingly interfere with normal function by their mere presence is only hinted at in this first paper (H.S.).]

Geschickter, C. F., O'Malley, W. E., Rubacky, E. P.: "A hypersensitivity phenomenon produced by stress: the 'negative phase' reaction." *Am. J. Clin. Pathol.* **34**: 1-8 (1960). C88,483/60

Various stressors inhibit the anaphylactoid reaction produced by egg white in the rat, but this may be followed by a "negative phase" of hypersensitivity. "Although the 'negative phase' is similar to Selye's exhaustion stage of the general adaptation syndrome, it differs by being a more acute, frequent, and repetitive occurrence, and of a lesser degree of severity than that observed with exhaustion."

Kinsell, L. W.: "Physiologic aging and radiologic life-shortening." *Fed. Proc.* **20**: 14-21 (1961). D12,597/61

Critical review of the literature on the induction of artificial aging by ionizing radiations, and its relation to natural aging. "There would appear to be no question that radiation, in common with many other physical agents, if used in sufficient amount, can produce in any cell, tissue, or organ a state in which catabolism goes on at a greater rate than anabolism." It remains to be seen, however, whether such changes are comparable to physiologic aging. On the other hand, "the stress of a life in which the threat of sudden death is ever present must certainly influence the aging process" (99 refs.).

Platner, W. S.: "The effect of stress on the aging process." *Mo. Med.* **58**: 373-376 (1961). D6,730/61

Trujillo, T. T., Spalding, J. F., Langham, W. H.: "A study of radiation-induced aging: response of irradiated and nonirradiated mice to cold stress." *Radiation Res.* **16**: 144-150 (1962). D24,525/62

In mice, resistance to standard "cold stress" showed a linear decrease with age. The same reaction was obtained after x-irradiation. "The radiation-induced effect was considered similar to life shortening by natural aging."

Selye, H.: *Stress und Altern* (Stress and aging), p. 20. Bremen: Angelsachsen-Verlag, 1962. D26,079/62

Review of the author's earlier observations on the relationship between stress and aging.

Curtis, H. J.: "Biological mechanisms underlying the aging process." *Science* **141**: 686-694 (1963). E24,424/63

In mice, exposure to x-rays or temporary treatment with mercury produced premature aging and death, but a number of other chemical stressors, though severe, did not noticeably shorten life expectancy under the conditions prevailing in these experiments. Hence the author doubts that stress, as such, invariably reduces lifespan.

Curtis, H. J.: "Cellular processes involved in aging." *Fed. Proc.* **23**: 662-667 (1964). F13,382/64

Review of the author's earlier experiments showing that a variety of stressors, such as nitrogen mustard, typhoid toxin, typhoid toxoid, tetanus toxin, subcutaneous turpentine and so on, administered chronically up to three times a week, did not significantly shorten the life expectancy of mice. "Attempts to obtain evidence for the wear and tear theory have all shown that a generalized stress is not necessarily life shortening. This does not mean that a specific stress agent causing irreparable damage to one organ might not result in a reduced life expectancy. For example, in mercury poisoning the kidney is irreparably damaged but the animal does not die for some time. In this case a 'weak link' is created and will be the first to break as the aging process advances."

Rotondo, G.: "Sull'impiego dell'acido adenosintrifosforico e della cocarbossilasi in piloti affetti da lieve o iniziale fatica di volo" (The use of ATP and cocarboxylase in pilots suffering from light or initial flying fatigue). *Riv. Méd. Aeronaut. Spaz.* **27**: 176-192 (1964). G19,344/64

Flying fatigue in jet pilots is ascribed to the exhaustion of adaptation energy. It is beneficially influenced by combined treatment with ATP and cocarboxylase (19 refs.).

Paré, W. P.: "Premature aging as a function of long-term environmental stress." *J. Genet. Psychol.* **104**: 185-191 (1964). G41,960/64

A review on the relationship between stress and aging revealed that the BMR decreases with old age, whereas the prostate undergoes hypertrophy. In experiments on rats chronically exposed to stressors (sound, electric shocks), aging (defined in terms of BMR and prostatic hypertrophy) was in fact accelerated. The animals also showed eosinopenia and lymphopenia. It was concluded

that "an animal's environment may 'require' or 'cause' adaptive responses that produce irreversible damage and hence shorten life span. A concept such as 'normal' aging may be misleading since aging cannot be represented as a unitary concept. Aging is the cumulative effect of responses made by biological systems as these systems adapt themselves to environmental stressors" (21 refs.).

Guth, P. H., Mendick, R.: "The effect of chronic restraint stress on gastric ulceration in the rat." *Gastroenterology* **46**: 285-286 (1964). G18,489/64

Restraint is very useful for producing experimental ulcers in the rat, but after a certain time adaptation occurs, and the ulcerogenic effect of this stressor diminishes during the phase of resistance.

Ordy, J. M., Rolsten, C., Samorajski, T., Collins, R. L.: "Environmental stress and biological ageing." *Nature* **204**: 724-727 (1964). F26,091/64

Fridrich, R.: "Die Auswirkungen von Kombinationsschäden auf den bestrahlten Organismus" (The effects of combined stress on the irradiated organism). *Strahlentherapie* **124**: 302-307 (1964). G19,723/64

In mice, production of stress by traumatic injuries (removal of part of the omentum) forty-eight hours before or after x-irradiation offers considerable protection. This type of increased resistance is ascribed to the stressor effect of pituitary-adrenocortical mobilization, since it can be blocked by morphine or barbiturates which inhibit hypothalamic reactivity (40 refs.).

Paré, W. P.: "The effect of chronic environmental stress on premature aging in the rat." *J. Gerontol.* **20**: 78-84 (1965). F31,169/65

From experiments on rats exposed to repeated electroshock and then tested for muscular fatigability or thermic contraction of tail tendon fibers, it was concluded that "the stress-induced changes in swimming speed and collagen contraction were valid signs of aging, since they were irreversible."

Vecsei-Weisz, P., Kemény, V., Harangozo, M.: "Further investigations concerning functional changes in the adrenal cortex at the resistance stage of the general adaptation syndrome." *Acta Physiol. Acad. Sci. Hung.* **27**: 265-273 (1965). G34,303/65

"The resistance stage of the general adaptation syndrome has been evoked in rats by

the repeated administration of formalin, and the resulting functional changes were studied by the in vitro incubation of surviving adrenal slices. The aldosterone production was found to be augmented, the corticosterone production unaltered. After adding a progesterone precursor to the incubation medium the rate of production of corticosterone and aldosterone increased. The increase in aldosterone production after formalin treatment was equal to that in the controls. The increase in corticosterone synthesis was more pronounced in formalin-treated animals."

Ouellette, R., Perrault, H. J., Dugal, L. P.: "Effet du froid sur le testicule endocrinien: chronologie des événements" (Effect of cold on the endocrine testis: chronology of events). *Rev. Can. Biol.* **24**: 7-21 (1965).

F42,194/65

In male rats, "a time study of the response of the sexual accessories reveals the succession of events as distinct phases related to the duration of the stress and reminiscent of the three stages of the General Adaptation Syndrome."

Gray, R. M., Baker, J. M., Kesler, J. P., Newman, W. R. E.: "Stress and health in later maturity." *J. Gerontol.* **20**: 65-68 (1965).

F31,165/65

Statistical studies showed that, among elderly people, those "who had experienced the most stress during the past ten years also had the poorest health scores. In addition, the data revealed that the severely disabled persons had significantly higher stress scores than did non-disabled older persons, which indicated that they had experienced more stress than the non-disabled."

Tintera, J. W.: "Stabilizing homeostasis in the recovered alcoholic through endocrine therapy: evaluation of the hypoglycemia factor." *J. Am. Geriatr. Soc.* **14**: 126-150 (1966).

F62,090/66

People genetically predisposed to alcoholism have evidence of hypocorticoidism and hypoglycemia. "By the continued use of alcohol the organism as a whole goes through the stages of alarm reaction, resistance, and eventually exhaustion." [The data are not subject to statistical evaluation (H.S.).]

Sobel, H.: "Stress and environmental factors in aging." *Psychosomatics* **8** No. 4, Sect. 2: 21-27 (1967).

F87,136/67

Ordy, J. M., Samorajski, T., Zeman, W., Curtis, H. J.: "Interaction effects of environ-

mental stress and deutron irradiation of the brain on mortality and longevity of C57BL/10 mice." *Proc. Soc. Exp. Biol. Med.* **126**: 184-190 (1967). F90,270/67

"Contrary to expectation, stress resulted in a significant decrease in mortality and a longer life span of both the non-irradiated and brain-irradiated mice." These findings are "consistent with evolutionary theories of natural selection and survival of multicellular populations under fluctuating environmental conditions." [A certain amount of stress is undoubtedly beneficial but, depending upon its kind and quantity, the reverse is undoubtedly also true. Protection against irradiation could be ascribed to cross-resistance (H.S.).]

Lang, C. M.: "Effects of psychic stress on atherosclerosis in the squirrel monkey (*Saimiri sciureus*)."*Proc. Soc. Exp. Biol. Med.* **126**: 30-34 (1967). F90,255/67

About two years of exposure to restraint, alone or combined with conditioned avoidance, accelerated the development of atherosclerosis, increased urinary 17-KS excretion and raised serum cholesterol.

Rahe, R. H., McKean, J. D. Jr., Arthur, R. J.: "A longitudinal study of lifechange and illness patterns."*J. Psychosom. Res.* **10**: 355-366 (1967). D88,215/67

A close relationship was found between stresses (as judged by the LCU questionnaire) and the frequency of disease, especially psychiatric illness, among U.S. Navy personnel.

Stark, E., Fachet, J., Makara, G. B., Mihály, K.: "An attempt to explain differences in the hypophyseal-adrenocortical response to repeated stressful stimuli by their dependence on differences in pathways."*Acta Med. Acad. Sci. Hung.* **25**: 251-260 (1968). G63,921/68

In rats, "certain non-specific stimuli that raise the plasma corticosterone level when administered on a single occasion fail to raise it when administered repeatedly whereas others raise it independently of the number of administrations. It is suggested that stressor agents reach the CRF-secreting hypothalamic cells by different pathways, and that the CRF-activating mechanism of some stressors does adapt itself to repeated stimuli, that of others does not."

Paré, W. P.: "Effect of duration of environmental stress on stomach ulceration and

adrenal ascorbic acid."*Psychol. Rep.* **23**: 683-688 (1968). J19,594/68

In rats repeatedly exposed to electroshock over a twenty-four day period, adrenal ascorbic acid showed an initial decline, followed by a rise far above normal by the end of the experiment [corresponding to the stage of adaptation (H.S.)]. In these animals, which were not deprived of food or water, gastric lesions developed only irregularly.

Glass, D. C., Singer, J. E., Friedman, L. N.: "Psychic cost of adaptation to an environmental stressor."*J. Pers. Soc. Psychol.* **12**: 200-210 (1969). G67,952/69

"Among a group of college females, the work of adapting to unpredictable, in contrast to predictable, noise resulted in lowered tolerance for frustration and in impaired performance efficiency after termination of the noise." These findings are compatible with the theory of adaptation energy depletion, but there is still no precise concept of what is being diminished.

Hodges, J. R., Mitchley, S.: "The effect of 'training' on the release of corticotrophin in response to minor stressful procedures in the rat."*J. Endocrinol.* **47**: 253-254 (1970). H26,814/70

Martin, M. S., Martin, F., Lambert, R.: "Effet de l'habituation sur la sensibilité du rat à l'ulcère de contrainte" (Effect of habituation on the sensitivity of the rat to restraint ulcer).*C.R. Soc. Biol. (Paris)* **164**: 826-828 (1970). H33,491/70

Rahe, R. H., Mahan, J. L. Jr., Arthur, R. J.: "Prediction of near-future health change from subjects' preceding life changes."*J. Psychosom. Res.* **14**: 401-406 (1970). J14,839/70

On the basis of the LCU questionnaire, it was possible to predict illness frequency among U.S. Navy personnel on three combat cruises, thus confirming the many earlier retrospective studies documenting the association between a subject's life stress and illness rate. "The finding, then, that the life change and subsequent illness hypothesis held up in the prospective test is perhaps more impressive when it is realized these experiments dealt with a very restricted portion of the spectrum of stress and disease" (23 refs.).

Selye, H.: "Stress and aging."*J. Am. Geriatr. Soc.* **18**: 669-680 (1970). G70,439/70

Brief review of data suggesting that the

phenomenon of aging may be due to the cumulative effect of repeated exposure to stress conducive to irreversible "chemical scars" in organs.

Árvay, A., Takács, I., Ladányi, P., Balogh, A., Benkő, K.: "The effect of intensive nervous stimulation on certain physico-chemical properties of rat tail tendon and uterus collagen." *Gerontologia* **17**: 157-169 (1971).

J16,955/71

The physico-chemical properties of rat tail tendon (quantity of labile hydroxyproline, changes in thermo-isometric tension) and uterine collagen during biologic aging and exposure to various stressors are essentially similar. These and EM studies led the authors to suggest that "long-lasting intensive stress, therefore, produced changes of such a degree and character which exceeded the physiological changes characteristic of and accompanying biological ageing."

Hall, D. A.: "The use of stress as a tool in gerontological research." *Age and Ageing* **1**: 141-145 (1972).

G93,666/72

"In the author's opinion, whatever phenomenon is observed, the results obtained under conditions of stress may well bear a closer relationship to the normal ageing condition than do determinations made under the rather specialized resting conditions in which such parameters are normally measured."

Bellamy, D.: "The thymus in relation to problems of cellular growth and ageing." *Gerontologia* **19**: 162-184 (1973).

J11,032/73

The thymus involution occurring during stress was compared to that of old age, but a causal connection between the two could not be established.

Damon, A., Roen, J. L.: "Aging in the Solomon islands and the United States: test of Pearl's hypothesis." *Hum. Biol.* **45**: 683-693 (1973).

J9,933/73

Pearl's hypothesis that "the length of life depends inversely on the rate of living" has been tested in Americans and Solomon Islanders, using the resting pulse rate as an index of "the rate of living." On this basis, it is concluded that "although the present evidence is equivocal at best, Pearl's hypothesis deserves further investigation in man, with appropriate measures of pace and duration of life." [Graying of hair was used as an indicator of physiologic aging. It is questionable whether resting pulse rates are accurate indices of the stress of life, and

graying of hair hardly reflects physiologic aging (H.S.).]

Everitt, A. V.: "The hypothalamic-pituitary control of ageing and age-related pathology." *Exp. Gerontol.* **8**: 265-277 (1973).

J8,461/73

Although aging is primarily under genetic control, the speed of its development may be influenced by hormones secreted under stress (about 100 refs.). [A review without additional new data (H.S.).]

Yanase, M.: "A study on the role of brain for the establishment of adaptation to the repeated immobilization stress. II. A role of the limbic-midbrain system in the repeated immobilization stress." *J. Physiol. Soc. Jap.* **35**: 171-178 (1973) (Japanese).

J17,716/73

In rabbits, ACTH release following repeated restraint diminished as a consequence of adaptation. This was not found after sectioning of the fornix. "Therefore, hippocampal inhibition of ACTH release is considered to correlate with the inhibition of ACTH release under the repeated stress, and hippocampus may play an important role in the establishment of adaptation to the stress."

Mikulaj, L., Kvetňanský, R., Murgaš, K.: "Changes in adrenal response during intermittent and repeated stress." *Rev. Czech. Med.* **20**: 162-169 (1974).

J16,273/74

In rats the initial marked corticosterone secretion was significantly diminished after twenty to forty-two days of repeated stress (restraint, formaldehyde). On the other hand, the adrenal medulla gradually increased its ability to release catecholamines as adaptation developed.

Welch, B. L., Brown, D. G., Welch, A. S., Lin, D. C.: "Isolation, restrictive confinement or crowding of rats for one year. I. Weight, nucleic acids and protein of brain regions." *Brain Res.* **75**: 71-84 (1974).

J14,176/74

Rats living for one year under stressful conditions of isolation or crowding have a diminished DNA content in their telencephalon. The authors suggest the tentative working hypothesis that "stress or high levels of environmental stimulation may accelerate the natural aging-associated loss of neurons from the brain."

Goldstein, A. L., Hooper, J. A., Schulof, R. S., Cohen, G. H., Thurman, G. B., Mc-

Daniel, M. C., White, A., Dardenne, M.: "Thymosin and the immunopathology of aging." *Fed. Proc.* **33**: 2053-2056 (1974).

H92,570/74

Thymosin, a low molecular weight acidic polypeptide isolated from thymus tissue, is probably a hormone. Its blood concentration is high in young and low in old people. Probably, the thymus, through secretion of thymosin and perhaps other hormones, can act at a distance and influence the function and development of lymphoid cells involved in cell-mediated immunity; thereby it participates in the aging process.

Grosch, H.: "Psychovegetative Störungen bei Erschöpfungszuständen" (Psychovegetative disturbances caused by exhaustion). *Med. Welt* **25**: 310-311 (1974).

H85,385/74

Review of empirical findings concerning the eventual onset of exhaustion in patients exposed to the stress of long-lasting organic diseases.

Yunis, E. J., Greenberg, L. J.: "Immunopathology of aging." *Fed. Proc.* **33**: 2017-2019 (1974).

H92,566/74

A review of the literature suggests that thymic involution and cellular immune dysfunction may influence the pathogenesis of aging, while its etiology requires a genetically programmed system involving genes linked to immune response loci.

Walford, R. L.: "Immunologic theory of aging: current status." *Fed. Proc.* **33**: 2020-2027 (1974).

H92,567/74

Normal immune function decreases, whereas autoimmunity increases with age. Alterations in thymus function may play an important role in regulating the immunopathology of aging (106 refs.).

Good, R. A., Yunis, E.: "Association of autoimmunity, immunodeficiency and aging in man, rabbits, and mice." *Fed. Proc.* **33**: 2040-2050 (1974).

H92,568/74

A review of the literature and personal observations suggesting that primary immunodeficiency diseases of man, as well as those produced by neonatal thymectomy and the ones that develop during aging in experimental animals, are all accompanied by several autoimmune phenomena and frequently by amyloidosis. Thus, antigens or organisms otherwise forbidden access to the body can penetrate or persist, abnormally stimulating residual immunologic systems (78 refs.).

Teague, P. O.: "Spontaneous autoimmu-

nity and involution of the lymphoid system." *Fed. Proc.* **33**: 2051-2052 (1974).

H92,569/74

In mice, neonatal thymectomy elicits changes reminiscent of premature aging. "Immunization of autoimmune strain mice with nuclear antigens is followed by anti-nuclear antibody production in older but not younger animals. Treatment of animals already producing this autoantibody with thymocytes results in disappearance of autoantibody and inhibits induction of antinuclear antibody by immunization. Thymectomy of young adults resulted in accelerated appearance of antinuclear antibodies in autoimmune strains. Aged mice of autoimmune strains were found to be deficient in T-lymphocyte function by several parameters as compared to syngeneic young mice. Aged mice of a strain lacking autoimmune potential did not show this decline. Thymectomy of young adults was shown to be followed by a severe impairment in T-lymphocyte function."

Tharp, G. D., Buuck, R. J.: "Adrenal adaptation to chronic exercise." *J. Appl. Physiol.* **37**: 720-722 (1974).

J18,803/74

Observations on rats chronically forced to exercise led the authors to the conclusion that "part of the diminished in vivo corticosterone release occurring with training is due to adaptation of the adrenal gland to ACTH stimulation."

Amster, L. E., Krauss, H. H.: "The relationship between life crises and mental deterioration in old age." *Int. J. Aging Hum. Dev.* **5** (I): 51-55 (1974).

J24,302/74

Busse, E. W.: "Criteria for determination of premature aging attributed to prisoner-of-war status." *J.A.M.A.* **231**: 521 (1975).

H98,500/75

"Secondary aging refers to changes resulting from stress, trauma, and infection (all factors in combat and internment)." The life expectancy of POWs after release may be normal or increased, depending upon circumstances during internment.

Warren, S., Chute, R. N., Porter, M. W.: "The effect of parabiosis on life-span of rats stressed by radiation." *J. Gerontol.* **30**: 15-21 (1975).

Rose, R. M., Hurst, M. W.: "Plasma cortisol and growth hormone responses to intravenous catheterization." *J. Hum. Stress* **1**: 22-36 (1975).

H97,894/75

In patients, the first catheterization tended to produce parallel rises in plasma STH and cortisol, but the STH responses were much more variable. In general, the findings "suggest a definite endocrine adaptation to catheterization by the second or third hour of the experience."

Selye, H., Tuchweber, B.: "Stress in relation to aging and disease." In: Everitt, A. and Burgess, A., *Hypothalamus, Pituitary and Aging*. In press. Springfield, Ill.: Charles C Thomas. G70,417/

Chapter emphasizing the influence of stress upon life expectancy.

STRESS AND FATIGUE

We touched upon the phenomenon of fatigue in the preceding section on adaptation energy, as well as in the section on Occupations (Aerospace) which deals with flying fatigue. A great deal of empirical information has been accumulated in relation to fatigue caused by diverse occupations, athletic activities and so on. There can be no doubt that fatigue is one of the consequences of systemic stress, but its mechanism is still too incompletely understood to justify detailed discussion here.

The syndrome of "pernicious fatigue," present on arising, then relieved, but recurring during the afternoon and again relieved in the evening, has been "conceived as a common physiologic reaction to stress," and without much evidence ascribed to hypoglycemia.

Fatigue, like stress, can be general or local, affecting the entire body or only one part, for example, the CNS or the muscular system.

Stress and Fatigue

(See also our earlier stress monographs, p. xiii)

Bartley, S. H., Chute, E.: *Fatigue and Impairment in Man* (Foreword by A. C. Ivy), p. 429. New York and London: McGraw-Hill, 1947. B34,753/47

Monograph on various types of specific organ system impairments and general fatigue. A wealth of empirical information without any reference to the stress concept.

Floyd, W. F., Welford, A. T.: *Symposium on Fatigue*, p. 196. London: H K Lewis, 1953. B86,075/53

Proceedings of a symposium in which numerous specialists discussed the criteria, measurement and mechanism of fatigue. Several sections deal with the relationship between physical and mental fatigue in stress.

[No special attempt has been made to estimate stress by objective indices (H.S.).]

Brouha, L.: "Fatigue—measuring and reducing it." *Adv. Management* 19: 9-19 (1954). B92,375/54

Discussion of fatigue in relation to stress in industry.

Bartley, S. H.: "Fatigue and inadequacy." *Physiol. Rev.* 37: 301-333 (1957). C39,912/57

Review of neural, hormonal, dietary and stressor effects on various types of fatigue affecting different functions (174 refs.).

Wachholder, K.: "Müdigkeit ein allgemeines Stress-Symptom infolge der Ausschüttung von ACTH?" (Is fatigue, a general stress symptom, caused by ACTH release?). *Int. Z. Physiol. Einschl. Arbeitsphysiol.* 16: 361-364 (1957). C39,970/57

About 50 percent of the patients who received a large dose of ACTH developed a feeling of generalized fatigue, whereas 30

percent reacted by becoming refreshed and alert. Apparently, there are individual differences in responsiveness, but ACTH discharged during stress may be responsible for the associated changes in mood.

Bugard, P.: *La Fatigue* (Fatigue), p. 308. Paris: Masson, 1960. C79,049/60

Somewhat technical discussion on the somatic and psychic manifestations of fatigue with reference to the G.A.S.

Jaffe, D. S.: "Fatigue states. Asthenic reactions." In: Cantor, P. D., *Traumatic Medicine and Surgery for the Attorney*, pp. 22-34. Washington: Butterworths, 1962.

E10,309/62

A chapter in an encyclopedia on legal medicine, concerning the relationship between stress and fatigue, especially in industry or after trauma.

Bartley, S. H.: *Fatigue. Mechanism and Management*, p. 96. Springfield, Ill.: Charles C Thomas, 1965. E5,041/65

Monograph on the causes of fatigue and the chemical changes associated with it. A special section deals with the participation of the G.A.S. (63 refs.).

Edholm, O. G., Bacharack, A. L. (eds.): *The Physiology of Human Survival*, p. 581. New York and London: Academic Press, 1965. E6,283/65

A monograph on human reactions to various stressors such as heat, cold, anoxia, high altitudes, compression and decompression, nutritional damage, sleep deprivation, monotony, fatigue, emotional arousal and muscular exercise. Each chapter is written by a specialist in the field, and numerous references indicate the difference between specific defense mechanisms and the stressor effect of the agents used.

J8,264/73

Review on fatigue in various occupations, with special reference to its participation in stress and in the diseases of adaptation.

Bugard, P.: *Stress, Fatigue et Dépression. (L'Homme et les Agressions de la Vie Quotidienne)* (Stress, fatigue, and depression. Man and the aggressions of daily life), Vol. 1, p. 294; Vol. 2, p. 302. Paris: Doin Edit., 1974.

E10,487/74

Kaye, P. L.: "Pernicious' fatigue. Identification, pathogenesis, and treatment." *Behav. Neuropsychiatry* 5: 24-29 (1974).

H88,050/74

Description of a type of "pernicious fatigue" that has a clearly diurnal cycle: present on arising, then relieved; recurring in the afternoon and again relieved in the evening. One manifestation of this syndrome is an overactivity of the autonomic, particularly the vagal, system with periods of dizziness, weakness, headaches and a general feeling of misery and anxiety. Frequently, there are flat glucose tolerance curves among these patients, but this is regarded as a symptom,

not a cause of the malady. Atropine is recommended to relieve the manifestations. The syndrome of pernicious fatigue has often been ascribed to low blood sugar, and an organization called "Hypoglycemia Foundation" exists (allegedly with a twenty-five

hundred-physician membership), but according to the author its claims and methods of treatment are entirely unjustified. "The syndrome is best conceived as a common physiologic reaction to stress." Ten case reports are presented (7 refs.).

VARIOUS OTHER THEORIES

It will not be necessary to discuss the many other theories proposed for the explanation of the G.A.S., since none of them have been clearly substantiated. The publications abstracted on the following pages call attention to the possible roles played by various not previously mentioned *organs, enzymes, RNA, cAMP, toxic substances* (especially bacterial endotoxins absorbed from the intestinal tract), and concepts based on *systems models* of stress.

Various Other Theories

(See also our earlier stress monographs, p. xiii)

Kidney. Gupta, D. das, Giroud, C. J. P.: "Experimental aminonucleoside nephrosis. (I): Action of cortisone on aldosterone and corticosterone production." *Proc. Soc. Exp. Biol. Med.* **98**: 334-339 (1958).

C55,024/58

In rats with nephrosis induced by puromycin aminonucleoside, aldosterone production is increased.

Ganong, W. F., Alpert, L. C., Lee, T. C.: "ACTH and the regulation of adrenocortical secretion." *N. Engl. J. Med.* **290**: 1006-1011 (1974).

H85,990/74

Excellent and very succinct review on factors regulating corticoid production. Aldosterone release occurs in the glomerulosa which, unlike the fasciculata and reticularis, undergoes no atrophy following glucocorticoid overdosage. Aldosterone secretion by the glomerulosa, on the other hand, is stimulated by angiotensin, and this effect is not prevented by corticoid-induced adrenocortical atrophy.

Liver. Tyler, F. H., Schmidt, C. D., Eik-Nes, K., Brown, H., Samuels, L. T.: "The role of the liver and the adrenal in producing elevated plasma 17-hydroxycorticosteroid levels in surgery." *J. Clin. Invest.* **33**: 1516-1523 (1954).

B99,414/54

Metabolic studies in man suggest that "the

increased plasma levels of 17-hydroxycorticosteroid after surgery are the result of both increased adrenal secretion of these steroids and impaired hepatic removal."

Yates, F. E., Urquhart, J., Herbst, A. L.: "Impairment of the enzymatic inactivation of adrenal cortical hormones following passive venous congestion of the liver." *Am. J. Physiol.* **194**: 65-71 (1958).

C56,413/58

In rats, venous congestion of the liver severely impairs enzymatic reduction of ring A in DOC, cortisone and cortisol. The same is probably true for aldosterone. "Secondary aldosteronism of congestive heart failure may be accounted for in part by this enzymatic lesion."

Dougherty, T. F., Berliner, D. L.: "The effect of stress and ACTH on the metabolism of hydrocortisone in the liver." In: Brauer, R. W., *Liver Function*, pp. 416-417. Washington: American Institute Biological Sciences, 1958.

J11,223/58

In vitro and in vivo experiments on mice show that ACTH inhibits the steroid-conjugating capacity of the liver. This reduces the rate of excretion and increases the blood steroid level.

Bohus, B., Endrőczi, E.: "The effect of endogenous diminution of corticosteroid level on pituitary-adrenocortical function." *Acta Physiol. Acad. Sci. Hung.* **25**: 351-358 (1964).

G33,534/64

In anesthetized dogs, connection of the

adrenal vein with the hepatic portal circulation led to a rapid increase in the corticoid concentration of the adrenal vein blood. Morphine prevented this elevation. Presumably, "the plasma corticosteroid level increases the pituitary-adrenocortical activity through a hormonal feed-back mechanism."

Yates, F. E.: "Contributions of the liver to steady-state performance and transient responses of the adrenal cortical system." *Fed. Proc.* **24**: 723-730 (1965). F41,048/65

Review of data concerning the part played by the liver in maintaining blood corticoid levels during stress (34 refs.).

Lempert, B. L., Sheikman, M. B., Petrova, T. S., Zaslavskaya, M. G.: "Corticosteroid response to stress in experimental toxic hepatitis." *Biull. Èksp. Biol. Med.* **71** No. 4: 21-24 (1971) (Russian). Engl. trans.: *Bull. Exp. Biol. Med.* **71**: 367-369 (1971).

J21,619/71

In rats stressed by restraint, the rise in plasma 11-OHCS was inhibited by toxic hepatitis induced by carbon tetrachloride. The decrease in adrenocortical responsiveness "may to some extent explain the lowering of the nonspecific resistance of the animal to various pathogenic agents in diseases accompanied by lesions of the liver parenchyma."

Enzymes. Yuwiler, A., Geller, E., Schapiro, S.: "Effect of neonatal corticoids on tryptophan pyrrolase and brain serotonin." In: Németh, S., *Hormones, Metabolism and Stress. Recent Progress and Perspectives*, pp. 215-228. Bratislava: Slovak Academy of Sciences, 1973. E10,470/73

In newborn rats a single injection of cortisol induces tryptophan pyrrolase, retards body growth and diminishes the 5-HT content of the brain. These results are discussed in relation to the function of tryptophan pyrrolase in stress.

RNA, DNA. Arimura, A., Bowers, C. Y., Schally, A. V., Saito, M., Miller, M. C.: "Effect of corticotropin-releasing factor, dexamethasone and actinomycin D on the release of ACTH from rat pituitaries in vivo and in vitro." *Endocrinology* **85**: 300-311 (1969). H15,815/69

Comparative in vivo and in vitro studies in rats led the authors to conclude that: "1) dexamethasone suppresses the action of CRF at the pituitary level, 2) this dexamethasone blockade does not develop immediately, 3) dexamethasone-blockade of CRF requires a

process which involves DNA-dependent RNA synthesis, and 4) the process of ACTH release by CRF does not require RNA synthesis" (34 refs.).

cAMP. Fleischer, N., Donald, R. A., Butcher, R. W.: "Involvement of adenosine 3',5'-monophosphate in release of ACTH." *Am. J. Physiol.* **217**: 1287-1291 (1969).

H18,307/69

Experiments with theophylline, vasopressin and methylxanthine (which influence cAMP activities), as well as determinations of cAMP in the pituitaries of intact or adrenalectomized animals, "strongly support the hypothesis that cyclic AMP is involved in the release of ACTH by rat pituitary tissue in vitro."

Birmingham, M. K.: "Stress in the test tube. Effects of ACTH and adenosine-3', 5'-monophosphate (cyclic AMP) on corticosteroid and lactic acid production in vitro." *Can. Psychiatr. Assoc. J.* **15**: 635-640 (1970).

G80,312/70

Paul, M. I., Květnanský, R., Cramer, H., Silbergeld, S., Kopin, I. J.: "Immobilization stress induced changes in adrenocortical and medullary cyclic AMP content in the rat." *Endocrinology* **88**: 338-344 (1971).

H35,409/71

Fortier, C., Labrie, F.: "Regulation of secretion." In: Berson, S. A. and Valow, R. S., *Peptide Hormones*, pp. 383-391. Amsterdam: North-Holland, 1973. J12,062/73

Review on the regulation of pituitary hormone secretion, with a separate section excellently summarizing available data on the role of cAMP as a mediator of the action of releasing factors upon the adenohypophysis.

Fortier, C.: "New frontiers in neuroendocrinology." In: Mogenson, G. J. and Calaresu, F. R., *Stevenson Memorial Volume on The Limbic System*. Toronto: University of Toronto Press. In press. J12,064/

A review on the origin and nature of various releasing factors, with special reference to a cAMP-dependent protein kinase initiating the synthesis and discharge of adenohypophyseal hormones. "The general concept that extracellular homeostasis is but an extension of intracellular homeostasis" becomes increasingly evident.

Various Toxic Substances (see also First Mediator). Selye, H.: "The prevention of

adrenalin lung edema by the alarm reaction." *Am. J. Physiol.* **122**: 347-351 (1938).

A7,154/38

In rats, an alarm reaction produced by EP, formaldehyde, cold, forced exercise or surgical trauma enhances resistance to the lung edema elicited by subsequent intravenous injection of EP. "This observation invalidates the possibility that the alarm reaction increases resistance only because it delays the absorption of toxic agents into the blood stream." The pulmonary edema normally produced in rats given large amounts of sodium chloride intravenously after bilateral nephrectomy can be prevented by an alarm reaction (forced exercise). This is a good example of cross-resistance.

Selye, H.: "The effect of the alarm reaction on the absorption of toxic substances from the gastro-intestinal tract." *J. Pharmacol. Exp. Ther.* **64**: 138-145 (1938).

A8,052/38

In rats, EP or histamine (which are normally not absorbed to any significant extent from the intestinal tract) readily enter the bloodstream when given orally during an alarm reaction produced by muscular exercise or cold. "It is concluded that the increased absorption of toxic substances, such as are usually present in the alimentary tract, probably plays an important part in the causation of the general damage resulting from various non-specific noxious agents."

Rosoff, C. B., Goldman, H.: "Effect of the intestinal bacterial flora on acute gastric stress ulceration." *Gastroenterology* **55**: 212-222 (1968).

G60,200/68

In rats, polymyxin B offers significant protection against acute stress ulcers elicited by restraint, probably because this nonabsorbable antibiotic reduces the coliform bacteria in the intestine. "This change in the flora results in a decrease in the motor tone of the stomach and cecum, and in the volume and concentration of gastric acid produced in response to the stress of immobilization. The protection offered by the coliform-poor state is eliminated when endotoxin is given to antibiotic-treated animals." Conversely, systemic administration of endotoxin increases both gastric acid and stress ulcers. "It is suggested that, under the conditions induced by stress, detoxification mechanisms suffer and permit absorbed bacterial products to reach the systemic circulation and stimulate the hypothalamus."

Nagler, A. L., Levenson, S. M.: "The nature of the toxic material in the blood of rats subjected to irreversible hemorrhagic shock." *Circ. Shock* **1**: 251-264 (1974).

J19,533/74

In rats exposed to hemorrhagic shock, there appeared a passively-transferable lethal factor in the plasma that caused death when transfused into animals in mild, reversible shock.

Walker, R. I.: "Endotoxin and stress." *Lancet* August 31, 1974, pp. 527-528.

H84,663/74

Review of earlier data on the possibly inadequate elimination of endotoxins entering the portal circulation during shock. Endotoxin was found in liver homogenates of mice stressed by x-irradiation or anoxia. It was probably derived from the intestine. "These findings should prompt consideration of aseptic endotoxin in patients undergoing various situations involving prolonged stress and those who, because of poor nutrition and/or poor general state of health, may not be able to maintain normal homoeostasis between the intestinal endotoxin pool and the body."

Gans, H., Matsumoto, K.: "The escape of endotoxin from the intestine." *Surg. Gynecol. Obstet.* **139**: 395-402 (1974).

H90,517/74

Many earlier investigators believed that the increased absorption of microbes or microbial toxins could be largely responsible for the development of shock during severe stress. By use of lead acetate-sensitized rats (which are very responsive to endotoxins), it could be shown that the absorption of bacterial endotoxins from the intestine is greatly augmented during osmotic, shock (57 refs.).

Filkins, J. P.: "Blood endotoxin detoxification after trauma and endotoxemia." *Physiologist* **17**: 221 (1974).

H89,896/74

In lead-sensitized rats, the endotoxin-detoxifying ability of liver homogenates was greatly increased twenty-four hours after trauma. Possibly, "a detoxifying protein is elaborated incident to trauma or endotoxemia; it may play an important role in host-defense against shock pathogenesis."

Mathematical Models. Urquhart, J., Li, C. C.: "Dynamic testing and modeling of adrenocortical secretory function." *Ann. N.Y. Acad. Sci.* **156**: 756-778 (1969).

H10,877/69

A review of the available literature that lends itself to the construction of models representing the various factors that regulate ACTH secretion and actions. Most of the work was performed on perfused canine adrenal glands subjected to several temporal patterns of stimulation by ACTH. [Such models can incorporate all known factors that influence adrenocortical secretion (chemical composition of the blood, blood flow, nervous stimuli, genetic elements, chronologic sequence of all stimulants, etc.) but of course, *in vivo*, the number of modifying circumstances is virtually infinite. Hence these models must necessarily be restricted to a description of known stimuli and modifying circumstances, the sequence of intermediates in biosynthesis and biodegradation of hormones, and the limited number of other variables which can be established only under highly specific conditions; thus, they have little predictive value when compared to data amenable to programming in a computer (H.S.).]

Stear, E. B., Kadish, A. H. (eds.): *Hormonal Control Systems* (Proc. Symp. Rancho Santa Fe, Calif., 1967), p. 304. New York: American Elsevier, 1969. E10,611/69

Proceedings of a symposium on biologic control systems, with contributions by various experts on the regulation of corticoid secretion. Special attempts have been made to develop mathematical models that lend themselves to computer simulation. The principal advantage of such systems is described as follows: "Computer simulations (models) of biological systems require that the static and dynamic characteristics of all the pertinent components and processes of the systems be identified and quantitatively specified; computer models are truly functional—they can change state with the flow of time, and therefore they expose the incompleteness of knowledge."

Yates, F. E., Brennan, R. D.: "Study of the mammalian adrenal glucocorticoid system by computer simulating." In: Stear, E. B. and Kadish, A. H., *Hormonal Control Systems* (Proc. Symp. Rancho Santa Fe, Calif., 1967), pp. 20-87. New York: American Elsevier, 1969. J12,012/69

Mathematical interpretation of biologic data led to an attempt at computer simulation (model) of the factors influencing glucocorticoid secretion.

Rashevsky, N.: "A note on the mathemati-

cal theory of the effect of nervous stress on coronary thrombosis." *Bull. Math. Biophys.* 31: 403-416 (1969). J23,247/69

Urquhart, J., Krall, R. L., Li, C. C.: "Adrenocortical secretory function—communications and control aspects." *Automatica* 6: 193-205 (1970). J11,823/70

After reviewing their observations on the stimulation of corticoid secretion by ACTH in the canine adrenal, the authors "have developed a seventh order state variable model of this process in terms of current knowledge about the mechanisms of cortisol biosynthesis. The modeling plays a dual heuristic role: (1) at the very least, it provides a phenomenological description of adrenocortical secretory function for use in larger models of pituitary-adrenal control mechanisms, and (2) it is an aid in evaluating postulated mechanisms by which ACTH acts on the kinetic parameters of cortisol biosynthesis."

Green, J. F., Miller, N. C.: "A model describing the response of the circulatory system to acceleration stress." *Ann. Biomed. Eng.* 1: 455-467 (1973). J10,890/73

"A mathematical model of the circulatory system based on the principles of venous return is described and applied to the condition of acceleration stress."

Papaikonomou, E.: *Biocybernetics, Bio-systems Analysis and the Pituitary Adrenal System*, p. 334. Purmerend: Nooy's Drukkerij, 1974. E10,437/74

A monograph that combines insight and wit in applying the principles of systems analysis strategy and biocybernetics to the study of the pituitary-adrenocortical apparatus in relation to the G.A.S. Sayers' hypothesis about the activation of ACTH secretion by a negative feedback due to increased utilization of glucocorticoids during stress was not supported by subsequent experiments. It was replaced by the theory of Yates that stress activates a controller of the system in the hypothalamus. Then Smelik provided evidence of an integral controller of the system with a derivative controller sensitive to negative rates of change of blood glucocorticoids. It is essential in studies concerning the regulation of corticoid secretion to consider the ACTH concentration of the blood, and the blood flow, as separate input variables, and to distinguish between the effect of free and protein-bound corticoids. A diagram summarizing the author's concept will be found on p. 1106.

Yates, F. E., Maran, J. W.: "Stimulation and inhibition of adrenocorticotropin release." In: Greep, R. O. and Astwood, E. B., *Handbook of Physiology. Section 7. Endocrinology*, Vol. 4, Part 2, pp. 367-404. Washington, D.C.: American Physiological Society, 1974. E10,758/74

General review of interactions in the hypothalamo-pituitary-adrenocortical system during stress with an attempt to summarize it in

the mathematical model presented in Figure 26.

Lumsden, D. P.: "Towards a systems model of stress: feedback from an anthropological study of the impact of Ghana's Volta river project." In: Sarason, I. and Spielberger, C., *Dimensions of Anxiety and Stress*. (In press). J15,030/

An attempt to present a model of stress as an open system, based mainly on anthro-

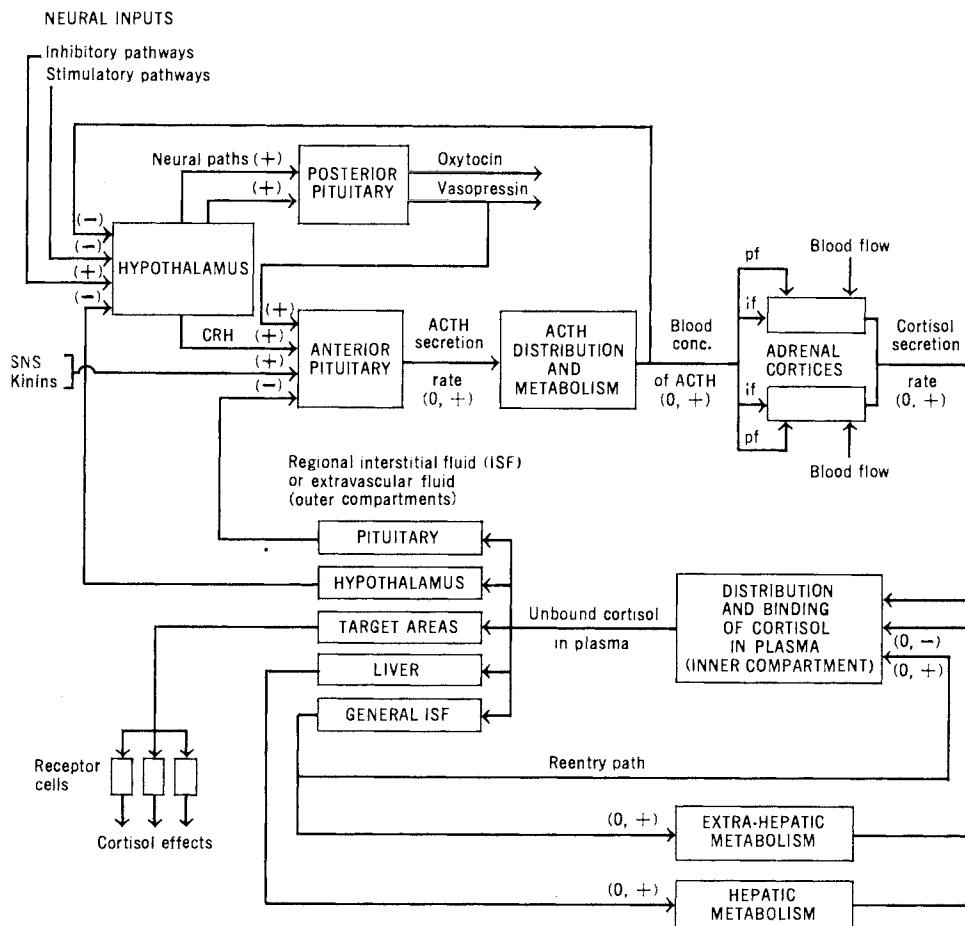

Figure 26. Complete block diagram of adrenal glucocorticoid control system. If, input forcing of adrenal by ACTH; pf, parametric forcing of adrenal (hypertrophic effect) caused by ACTH over a longer time period. Parametric effect of changes in adrenal blood flow is also indicated. The designators 0,+ and 0,- indicate that signals in pathways are restricted in values (e.g., there are no negative masses or frequencies and removal processes or inhibitors are negative in effects. Sign restrictions described in Dallman and Yates, *Ann. N.Y. Acad. Sci.* **156**: 696-721/1969. (Reproduced from *Handbook of Physiology* (1974), Section 7. Endocrinology, Fig. 8, p. 386, by permission of F. E. Yates and J. W. Maran and the American Physiological Society.)

pologic studies within the frame of Ghana's Volta river project (about 100 refs.).

Varia. Tuttle, E.: "Intracellular biochemical adaptation process therapy theory." *Rev. Gastroenterol.* **20:** 893-912 (1953).

J12,184/53

Highly speculative review on the mechanism of the G.A.S. (84 refs.).

Briggs, F. N., Munson, P. L.: "Studies on the mechanism of stimulation of ACTH secretion with the aid of morphine as a blocking agent." *Endocrinology* **57:** 205-219 (1955).

C7,791/55

In rats, morphine blocked ACTH secretion induced by various stressors (histamine, EP, vasopressin, laparotomy) or unilateral adrenalectomy, whereas these stimuli were effective in anesthetized controls. The action of exogenous ACTH was not blocked by morphine, showing that the drug fails to interfere directly with the response of the adrenal cortex.

Goldstein, M. S., Ramey, E. R.: "Non-endocrine aspects of stress." *Perspect. Biol. Med.* **1:** 33-47 (1957).

C61,319/57

While the importance of the G.A.S. (and particularly of the pituitary-adrenocortical axis) in adaptation is recognized, the non-endocrine aspects of stress responses are considered to be equally indispensable and are described in detail.

Dedichen, J., Laland, P., Laland, S. G.: "The effect of material prepared from ox blood on cold stress in mice." *Acta Pathol. Microbiol. Scand.* **58:** 219-224 (1963).

E22,664/63

High molecular material prepared from ox blood after exposure to stress significantly reduces the mortality of cold-stressed mice. "It is suggested that the material is related to a hypothetical resistance factor mentioned in the work of Raškova and Vaneček."

Wilder, J.: *Stimulus and Response. The Law of Initial Value*, p. 352. Bristol: John Wright & Sons, 1967.

E630/67

Monograph on the law of initial value, which states that the higher the initial value of some physiologic parameter (blood pressure, pulse rate), the more pronounced is its tendency to decrease and the smaller its tendency to rise under the influence of various agents. Numerous observations are mentioned which indicate that this law plays an important role in determining variable courses of changes characteristic of the G.A.S. (843 refs.).

VII. VARIOUS OTHER RELATED TOPICS

LEGAL IMPLICATIONS

Stress as a cause of disease has often been invoked in the courts to support the cases of plaintiffs who developed various illnesses following exposure to unusual demands for adaptation, especially at work or in concentration camps. Pertinent data that may be useful to the attorney will be found in the sections dealing with the corresponding stressors, such as noise, magnetism, vibration, shift work, aerospace, travel, ATC activities, industry (particularly mining), trauma and so on.

Of course it must be realized that stress is rarely the sole cause of any disease; yet it may play a role in almost all maladies, especially those discussed in the section Diseases of Adaptation (such as hypertension, cardiac accidents, neuropsychiatric disorders, peptic ulcers, sudden death of unknown cause, and even diabetes, asthma, menstrual disturbances or impotence).

The most important thing to remember in the evaluation of such cases is that diseases of stress are always pluricausal, in that they depend on both the stressor and the conditioning circumstances (genetic predisposition, previous illness, antecedent surgical operations, diet). It is evident that in all such lawsuits, if the defendant is found to be responsible for exposing the plaintiff to undue stressors, the main problem is to determine the relative parts played by stress and by conditioning factors respectively. This can never be accomplished with absolute quantitative accuracy, since neither the stressor effects nor the conditioning factors can be measured precisely. Yet a fairly close approximation of the defendant's share in the responsibility has often been possible when the attorneys have based their case on well-supported data in the medical literature, evaluated in collaboration with competent physicians.

It is not within the scope of this treatise, nor the field of competence of its author, to discuss the topic of jurisprudence adequately, but a few points that have often been raised in connection with the legal implications of stress might be enumerated briefly.

1. Both physical and emotional stressors can cause illness.
2. A great variety of diseases and disabilities may be precipitated by stress, even those not usually considered to be diseases of adaptation. As previously stated, in every person the weakest, most predisposed organ system will break down under the general demand of adaptation to stress, as the weakest link breaks in a chain exposed to mechanical stress.
3. The "survivor syndrome" of previous concentration camp inmates has clearly demonstrated that stress can induce delayed manifestations long after the stressor has ceased to act. This is especially true of psychologic disturbances or of psychogenic so-

matic lesions. Indeed, it has been argued that even the offspring of concentration camp inmates may be damaged, because they are brought up by parents with permanently warped mental attitudes. Although these delayed effects have been studied mainly on the large available population of concentration camp survivors, the conclusions presumably are applicable to persons exposed to other stressors of equal severity and duration.

4. Stress undoubtedly increases accident proneness (for example, in industry, driving, aerospace, travel, ATC work and combat).

5. Acting as a witness, judge, attorney or juror can in itself be extremely stressful and can influence performance in sensitive individuals.

These are a few of the most striking facts that emerge from the study of the pertinent literature, but their evaluation in the light of the laws of each country must be left up to legal experts.

Legal Implications

Review of the role played by the G.A.S. in legal medicine.

Sparkman, D. R.: "Trauma or strain and heart disease. Causal relationship." *Calif. Med.* 94: 72-76 (1961).

D1,913/61

To clarify the problems of the cardiac patient under workmen's compensation laws, a special committee of the Washington State Heart Association stated that a "causal relationship of trauma to heart disease may exist under the following circumstances: Sudden death from acute coronary disease (or coronary occlusion with myocardial infarction, or acute coronary insufficiency) in which symptoms develop during the course of or immediately following exertion or strain that is both excessive and unusual for the particular individual concerned; this exertion or strain may be either physical or emotional." In the years 1950-59, 77 percent of the claims for cardiac damage made in the state of Washington were for myocardial infarction or acute coronary insufficiency following unusual effort. Since CHD is progressive, it is difficult to ascertain when a given

stress at work may have contributed to an eventual infarct. Data on steps taken by several states concerning a causal relationship of stress to heart disease are reviewed (20 refs.).

General characterization of stress ulcers, mainly for the benefit of attorneys.

PHILOSOPHIC IMPLICATIONS

The philosophic and particularly the behavioral implications of research on the somatic and mental consequences of the stress and G.A.S. concepts have stimulated a great deal of work, not only by professional philosophers and behavioral scientists, but also by theologians, writers of fiction and nonfiction, paleontologists, motion picture and television producers, painters, and recently, even choreographers. My own thoughts on this subject were stated most concisely in *Stress Without Distress*, with a short summary on pp. 32-34 of this book.

As Dubos has so poignantly put it, human life is shaped by three classes of determinants: (1) the genetic code, (2) adaptation to environmental sources, and (3) the ability to choose among alternatives.

Actually these three factors are all interdependent, in that our genetic makeup determines the type of responsiveness to environmental stimuli and the ability to choose among possible alternatives.

A clear distinction between the specific and the nonspecific, as well as an awareness of the fundamental fact that specificity is always relative (with an infinite range between the two extremes of total specificity and total nonspecificity), are by no means limited to medicine and physiology. Our whole philosophy of life, and especially the justification of our behavior, must take these factors into consideration. It has been a most stimulating experience to attempt the development of a code of behavior based exclusively on natural laws, particularly those regulating efficient homeostasis. There appears to be a great similarity between the laws governing the maintenance of a healthy equilibrium, and those assisting us to achieve the satisfaction of success in reaching whatever goal we consider worthwhile, both on the somatic and on the mental

level. Of course, our efforts represent only a beginning; much more work is needed to develop the applications of a natural code of behavior to the innumerable problems encountered during a normal lifespan. However, we have identified a few examples of clearcut similarities between the somatic behavior of a person on the cellular and molecular level on the one hand, and his efficient aim-oriented attitude toward the challenges of his environment (including his society) on the other. Even this beginning offers hope to replace superstition, and blind faith in allegedly infallible authorities, by guidelines based on scientific research subject to objective verification.

Philosophic Implications

Selye, H.: "Creative health for all Canadians." *Health* (Toronto) **31**: 14-15 (1963).

E24,123/63

First attempt to formulate a code of behavior based upon natural laws, particularly the results of stress research.

Mason, J.: "Don't eliminate tension." *Bus. Management* August 1964, pp. 37-38.

J17,432/64

On the basis of speculative considerations on the effect of stress upon the body, the author concludes that "a reasonable number of anxieties and personal conflicts are often good for employees."

Farber, S. M., Mustacchi, P., Wilson, R. H. L. (eds.): *Man Under Stress*, p. 173. Berkeley and Los Angeles: University of California Press, 1964. E4,227/64

Proceedings of a symposium organized by the University of California. A group of physicians, surgeons and basic research men (among them Brock Chisholm, René Dubos, Seymour Farber, Stanley Sarnoff, Hans Selye and Paul Dudley White) discussed the various aspects of stress, particularly in relation to the philosophy of life, social environment, cardiovascular disease, space medicine and so on. Most of the speakers refrained from highly technical discussions, but key references to scientific papers are given.

Arangüena-García-Inés, C.: "El médico neohipocrático y la conducta del hombre ante el stress" (The neohippocratic physician and the behavior of man in relation to stress). *Folia Clin. Int. (Barc.)* **17**: 27-32 (1967).

J22,402/67

The author develops an entirely new philosophic interpretation of disease on the basis of the stress concept.

Reeves, R. B. Jr.: "What happens to the patient's religion?" *Delaware Med. J.* **45**: 40-43 (1973). J19,880/73

A pastor describes his experience in the change of the religious feelings of patients in hospitals. "We are dismayed by our own humanity, unable to accept our creatureliness as proper to our being, unable to love ourselves. This, of all the stresses a patient may suffer, can be the most disturbing."

Laszlo, E.: *Introduction to Systems Philos-*

ophy, p. 328. New York, San Francisco and London: Harper & Row, 1973. E10,096/73

Selye, H.: "Stress without distress in teamwork." *Viewpoint* November 1973.

J4,207/73

Brief outline of the behavioral lessons derived from the stress concept as applied to daily problems. Essentially a preview of the points developed in *Stress Without Distress*.

Leyhausen, P.: "The biological basis of ethics and morality." *Sci. Med. Man* 1: 215-235 (1974). J19,699/74

A biologic approach to the understanding of ethics (what we mean when we term something good or bad) and morality (what to do about something that is good or bad). The naturalists called "peristostable" those characteristics which developed in every case, even under the most diverse conditions, and "peristolabile" those characteristics which varied more readily, depending upon postnatal influences. "In other words, there never was any question of characteristics or traits being developed by genes alone," as environmental factors were always considered to be vital conditions. Altruistic behavior is one of the favorite examples of the anti-Darwinist critique; to substantiate a biologic basis for moral and ethical behavior, "we must first show that evolution in some ways and certain cases rewards sacrifice, including self-sacrifice, and that this fact neither directly contravenes the principle of the 'survival of the fittest' nor is excluded by it." Even refraining from suicide is an act of altruism if we consider our lives a liability we owe to God and/or society. If, in schools of fish, some swim at the periphery where they are most exposed to attack, this protects those in the central core through what the author considers "altruism." Certain instincts are used only once in a lifetime; they are called "templates" for the whole series of possible life events, and are kept in a state of readiness. Such "Innate Releasing Mechanisms" represent an a priori code of conduct. These and other considerations lead the author to outline a biologic basis for ethics and morality, but no effort is made to translate this into a prescriptive code of behavior in daily life.

Maston, J. W.: "The integrative approach in medicine. Implications of neuroendocrine mechanisms." *Perspect. Biol. Med.* 17: 333-347 (1974). H87,007/74

Discussion of the relative merits of "inte-

grative" and "analytical" approaches to exploring the stress response. Special emphasis is placed upon the facts that, at least in higher animals, the characteristic pituitary-adrenal responses are largely affected by CNS stimuli, and that the stressor effect of each agent is only relatively nonspecific since it is influenced by various responses characteristic of individual agents and conditioning factors.

Selye, H.: "Stress and distress. The first preview of a forthcoming book on how you and your patients can master stress." *Physicians World* 2 No. 3: 25-28 (1974).

J4,239/74

Brief, popular summary of *Stress Without Distress*, with special emphasis upon the behavioral implications of stress research and an attempt to formulate a code of ethics based exclusively on natural laws.

Dubos, R.: "Homeostasis, illness, and biological creativity." *Lahey Clin. Found. Bull.* 23: 94-100 (1974). J17,042/74

Excellent lecture on homeostatic reactions regulating man's somatic and mental behavior in health and disease. Human life is shaped by three classes of determinants: (1) the genetic code, (2) adaptation to environmental forces and (3) the ability to choose among alternatives.

EPILOGUE

At the end of this treatise I would like to present in retrospect some general thoughts that have occurred to me during the long labor of writing this work.

First, it may be useful to point out for those who see the finished product that it represents forty years of work, which began in 1935 when we performed the first primitive experiments published the following year in a brief letter to the editor of *Nature*. In the years since then I have spared no time or effort in my untiring drive to clarify the role of nonspecific reactions affecting living beings in health and disease. I have written quite a number of reviews and smaller monographs on the subject, always postponing the task of the "grand synthesis" until I had more evidence and understood the subject better. However, there seems to be no natural endpoint in sight. I keep on learning more and more, but I am afraid that my ability to learn and understand begins to lag behind both the explosive growth of information to be dealt with and my own capacities of evaluation.

EPILOGUE

At the end of this treatise I would like to present in retrospect some general thoughts that have occurred to me during the long labor of writing this work.

First, it may be useful to point out for those who see the finished product that it represents forty years of work, which began in 1935 when we performed the first primitive experiments published the following year in a brief letter to the editor of *Nature*. In the years since then I have spared no time or effort in my untiring drive to clarify the role of nonspecific reactions affecting living beings in health and disease. I have written quite a number of reviews and smaller monographs on the subject, always postponing the task of the "grand synthesis" until I had more evidence and understood the subject better. However, there seems to be no natural endpoint in sight. I keep on learning more and more, but I am afraid that my ability to learn and understand begins to lag behind both the explosive growth of information to be dealt with and my own capacities of evaluation.

Today, at the age of 68 I feel that the best service I can render to those interested in my favorite subject, stress, is to coordinate and compile what I know as best I can, before I lose the strength to undertake such a gigantic task. Now that the concepts of stress and of the diseases of adaptation are clearly defined, I think it is important to give a panoramic overview of the subject, for with the tremendous increase in data it becomes increasingly difficult to retain the proper perspective. As in all correlative subjects—such as understanding of the nervous system, intermediate metabolism or endocrine activity—even the most profound study of one restricted area is meaningless if its manifold interactions with other parts are neglected. Many specialists know a great deal about individual aspects of stress research, but few (if any) generalists are still capable of seeing the field as a whole. Even if some subjects had to be merely catalogued with little or no interpretation, it is better to have a manageable synopsis, no matter how imperfect, than to possess no general overview at all.

Only by carefully compiling a data inventory, a veritable encyclopedia of stress research, can this holistic approach be attempted. It is for this reason that I collected every publication that we could trace through the literature and every bit of information that we managed to obtain by personal research. Of the 110,000 references in my documentation service I have selected about 7 percent, either because they dealt with fundamental problems or themselves provided key bibliographies that would help the reader find virtually anything pertaining to stress in medicine, biochemistry, or daily life that he might choose to pursue further.

Fortunately, I have had a very large staff of excellent coworkers to assist me both with the laboratory and the bibliographic research required for compiling this encyclopedia; yet in order to maintain a unified perspective, I wrote every line of it myself. I know that many chapters could have been presented much better had I delegated them to experts in each respective topic, but then we would have ended up with yet another of those monumental, disjointed handbooks or proceedings of symposia on stress, in which some topics are repeated or overemphasized, others overlooked. Probably the time is not far away when volumes of this scope can no longer be written by any one author (in fact it occurred to me in my more pessimistic moments, while involved in this task, that perhaps that time had already arrived), but at any rate, I have attempted to present a balanced picture of my topic.

As I approach the end of my career I do not regret having had to sacrifice virtually my whole private life to accomplish this task, nor even, to be honest, the hardships I had to inflict upon my many coworkers who—some enthusiastically, some by necessity—helped me with my effort, which certainly could not have been achieved without them. The occasional doubt and remorse that I must admit to having experienced has left no permanent scar, for as I said in the introductory outline, I do believe in “altruistic egoism,” in trying “to earn thy neighbor’s love”—meaning the love of most neighbors, even at the unavoidable expense of irritating a few. I have spent my life guided by these principles, and as far as possible, have tried to encourage my coworkers to do likewise. Scientific objectivity demands, of course, that I admit to being somewhat prejudiced by four decades of one-sided activity, but at the end of this labor I still believe that I could not have used either my own time or that of my associates any better by doing something else. At the present period of history, stress in health and disease is medically, sociologically and philosophically the most meaningful subject for humanity that I can think of.

I am considering with my editors the possibility of writing a second edition or annual addenda as time goes by, if this work proves to be successful as a guide to future stress

research. Indeed, it may be necessary, owing to advances in stress research and the deterioration of one of its guardians, to use the present monograph merely as a basis for a more detailed encyclopedia to be written later, in which the advantage of a single coordinating author would have to be sacrificed in favor of an editor assigning each section to a more qualified specialist.

Meanwhile, let me conclude by expressing the hope that, even as it stands, uneven in workmanship and incomplete, this treatise will, at least for some time to come, help investigators find their way through the mass of information that has accumulated on the role of stress in health and disease.

SUBJECT INDEX

In this index, an arrow is used to indicate the effect of one agent upon another. For example, ACTH → inflammation indicates the effect of ACTH upon inflammation; blood vessels ← corticoids indicates the effect of corticoids upon blood vessels. The symbol + is employed when two or more agents act conjointly (for example, electricity + adrenalectomy). Only such simple signs are used. Letters or numerals identifying structural details of chemical compounds do not determine the placement of the entry (for example, γ-aminobutyric acid is entered under A, 5-HT under H, and so on).

It would defeat the purpose of indexing if we were to place *stress* as the keyword with each entry. Therefore, entries are indexed as factors concerned with stress. Boldface numerals refer to principal discussions of a subject. Figures relating to a particular topic are indexed by their number followed (in parentheses) by the number of the page on which they appear.
